4. If the red LEDs did light, as explained above, then go to Step 6. If the red LEDs do NOT light, as explained above, then go on to Step 5.

5. Restart the affected port network:
  - 1 Restart the PN by resetting its Expansion Interface circuit pack using `reset port-network P level 2`, using the port network's number of the affected PN. (Use the `list cabinet C` command to determine the port network's number for a given cabinet and carrier.)
6. Test the new IPSI or Tone-Clock circuit pack to verify that it is functioning properly, using `test tone-clock location long`, and verify that the system is operational by placing several phone calls. Where possible, try calls into, out from, and within the affected port network.

## Port Networks with Two Tone-Clock Circuit Packs

Notes:

1. Use `list cabinet C` to determine the port network's number of the cabinet and carrier containing the Tone-Clock circuit pack to be replaced. If both of a PN's Tone-Clock circuit packs need to be replaced, first replace and test the one in standby mode by either:
  - 1 Entering `status port-network` to display its status
  - 1 Making sure its amber LED is off

Make sure it is healthy and active before replacing the second one.

The active/standby state of a Tone-Clock circuit pack may also be determined by looking at its LED. A continuously lit red LED on the Tone-Clock circuit pack indicates a reported fault on one or more of the maintenance objects on the circuit pack. Flashing patterns of the yellow and green LEDs correspond to the following service states:

| Condition                                      | Tone-Clock Circuit State | Explanation                                                                                       |
|------------------------------------------------|--------------------------|---------------------------------------------------------------------------------------------------|
| Flashing yellow 2.7 seconds on, .3 seconds off | Active                   | An external timing source is being used as a synchronization reference. <sup>1</sup>              |
| Flashing yellow .3 seconds on, 2.7 seconds off | Active                   | The local oscillator on the Tone-Clock circuit pack is being used as a synchronization reference. |
| Yellow on continuously                         | Active                   | The circuit pack has been reset but has not been told which synchronization source to use.        |
| Yellow LED off                                 | Standby                  | The circuit pack is in standby mode, (neither generating tones nor supplying clocks).             |
| <b>1 of 2</b>                                  |                          |                                                                                                   |

| Condition                                                                                                 | Tone-Clock Circuit State | Explanation                                                                                                                                      |
|-----------------------------------------------------------------------------------------------------------|--------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------|
| "Jingle bells" green and yellow<br>.1 sec on, .2 sec off, .1 sec on,<br>.4 sec off, .4 sec on, .4 sec off | Standby                  | Maintenance software is testing the standby circuit pack (the standby Tone-Clock is providing tones).                                            |
| Double blink yellow .3 sec on, .3 sec off, .3 sec on, 2.4 sec off                                         | Active                   | TN2182 has lost all external references and is in holdover mode.                                                                                 |
| Other green and yellow patterns                                                                           | Active                   | Maintenance software is testing the active circuit pack.                                                                                         |
| Random yellow                                                                                             | Standby                  | If the circuit pack is a TN2182, the yellow LED may come on and off intermittently as ETR-PTs on the board are used for tone detection services. |
| <b>2 of 2</b>                                                                                             |                          |                                                                                                                                                  |

1. For a Tone-Clock in the master port network, the external source is the primary or secondary DS1 source, or a Stratum 3 clock. For a Tone-Clock in a slave port network, the external source is the Expansion Interface circuit pack.

1. If the Tone-Clock circuit pack to be replaced is active, then switch to the other Tone-Clock circuit pack by the following procedure:
  - a. **set tone-clock location**, where *location* is the physical address of the standby Tone-Clock circuit pack.

**Note:**

For a critical-reliability system (duplicated PNC), the system generally expects a PN to have its "preferred" Tone-Clock circuit pack active. For the first PN in a given cabinet, this is carrier A. For a second PN in the cabinet, this is carrier E.

- b. If the interchange was not successful, the standby Tone-Clock circuit pack may be defective. In particular, if the error message **must use override** is displayed, fix the standby Tone-Clock circuit pack before attempting to replace the active one.
2. Pull out the defective Tone-Clock circuit pack. No calls should be affected. If this is a TN2182 circuit pack, some ETR-PTs may be in use and removal of the pack will affect some individual users. It may be less disruptive to busyout the standby TN2182 before removing it.
3. Insert a new Tone-Clock circuit pack of the appropriate code in the same slot where the defective Tone-Clock circuit pack was removed.
4. Test the new Tone-Clock circuit pack using **test tone-clock location long** to make sure it is functioning properly. If the Tone-Clock circuit pack is being replaced due to loss of clocks, the Clock Health Inquiry (#46) will still report a failure, proceed with the next step.

- To verify that the new Tone-Clock circuit pack can generate clocks for the system, switch to the new Tone-Clock with `set tone-clock location override`, and enter `test tone-clock location`. If the new Tone-Clock circuit pack is able to generate system clocks, there will be no system disruption.

**! CAUTION:**

If the new Tone-Clock circuit pack is not able to generate system clocks, this procedure becomes destructive. The system will detect a loss of clock and recover by resetting the PN (PN cold restart).

After the restart, the faulty Tone-Clock circuit pack will be in standby mode.

- Place several phone calls.

## IPSI/Tone Clock LED States

For the TN2312 IPSI circuit pack, there are four LEDs on the IPSI's faceplate. The top three LEDs are the standard ones found on any TN circuit pack. The fourth LED imitates the TN2182B Tone-Clock's amber LED. The active/standby state of an IPSI or Tone-Clock circuit pack may also be determined by looking at its LEDs. A continuously lit red LED on the circuit pack indicates a reported fault on one or more of its MOs. Flashing patterns of the yellow and green LEDs correspond to the following service states:

**Table 267: LED Condition/Tone-Clock Circuit States 1 of 2**

| Condition                                            | Tone-Clock Circuit State | Explanation                                                                                               |
|------------------------------------------------------|--------------------------|-----------------------------------------------------------------------------------------------------------|
| Flashing yellow<br>2.7 seconds on<br>0.3 seconds off | Active                   | An external timing source is being used as a synchronization reference <sup>1</sup> .                     |
| Flashing yellow<br>0.3 seconds on<br>2.7 seconds off | Active                   | The local oscillator on the IPSI or Tone-Clock circuit pack is being used as a synchronization reference. |
| Yellow on continuously                               | Active                   | The circuit pack has been reset but has not been told which synchronization source to use.                |
| <b>S8700-series Fiber-PNC:</b> yellow LED off        | Standby                  | The circuit pack is in standby mode, (neither generating tones nor supplying clocks).                     |
|                                                      |                          | <b>1 of 2</b>                                                                                             |

**Table 267: LED Condition/Tone-Clock Circuit States 2 of 2**

| 3856 (q)         |              |                                                     | MAJ                     | ON           | <code>set tone-clock<br/>location override<sup>1</sup></code> |
| 3857<br>3858 (r) |              |                                                     | MAJ                     | ON           | <code>busyout/release<br/>ipserver-interface</code>           |
| 3872 (s)         | 0            |                                                     |                         |              | <code>set tone-clock<br/>location override<sup>1</sup></code> |
| 3999 (t)         | Any          |                                                     |                         |              |                                                               |
|                  |              |                                                     |                         |              | <b>2 of 2</b>                                                 |

1. For a TN2312 IPSI supported port network, use the command `set ipserver-interface`.

2. Minor alarms on this MO may be downgraded to Warning based on the value in `set options`.

Notes:

- a. **Error Type 0:** run the short test sequence first. If every test passes, run the long test sequence. Refer to each appropriate test's description, and follow its recommended procedures.
- b. **Error Type 1:** this error indicates the circuit pack totally stopped functioning or it was physically removed from the system.

**Note:**

The alarm is logged approximately 11 minutes after the circuit pack is removed/ SAKI Sanity test (#53) fails.

If the circuit pack is not present in the system, insert a circuit pack in the slot indicated by the error to resolve the error.

If the circuit pack is present in the system, it is faulty and must be replaced. See [Replacing the IPSI or Tone-Clock Circuit Pack](#).

If the faulty circuit pack is in standby mode, a MINOR alarm is raised, but no other system action is taken. If the circuit pack is the active Tone-Clock, further effects of this error depend on the system's reliability option.

**Table 269: Effects of Tone-Clock Failures Depending on Reliability MTAR**

| Reliability Option | Effects                                                                                                          |
|--------------------|------------------------------------------------------------------------------------------------------------------|
| Standard           | EPN goes down                                                                                                    |
| Duplex             | PN goes down.                                                                                                    |
| High               | IPSI interchange in IPSI connected PN<br>non IPSI connected PN goes down                                         |
| Critical           | IPSI interchange in IPSI connected PN<br>Interchange to standby Tone-Clock circuit pack in non IPSI connected PN |
|                    |                                                                                                                  |

If an interchange is attempted in an MCC PN *and* the system is unable to activate the standby Tone-Clock, Emergency Transfer is activated. When this happens, both circuit packs are faulty and must be replaced. See [Replacing the IPSI or Tone-Clock Circuit Pack](#).

If a successful interchange occurs in response to a failure of the active Tone-Clock or if a standby Tone-Clock fails, the faulty Tone-Clock should be replaced.

- c. **Error Type 18:** the indicated IPSI or Tone-Clock circuit pack has been made unavailable by `busyout tone-clock location` or `busyout ipserver-interface location`. This error applies only to high- or critical-reliability systems (an active Tone-Clock may not be busied out). To resolve this error, enter `release tone-clock location`, or `release ipserver-interface location`.

- d. **Error Type 23:** the circuit pack has been logically administered but not physically installed. Installing the circuit pack will resolve the alarm.
- e. **Error Type 125:** a wrong circuit pack is inserted in the slot where this circuit pack is logically administered. To resolve this problem, either:
  - 1. Remove the wrong circuit pack, and insert the logically administered circuit pack.
  - or
  - Use the `change circuit-pack` command to re-administer this slot to match the circuit pack inserted.
- f. **Error Type 126:** the port network specified in the **PORT** field of the error log entry booted up without a Tone-Clock circuit pack, or with a one that cannot communicate at all with the system. The error is logged five minutes after the port network is restarted. If no circuit pack is present, install one of the proper code. If there is a circuit pack present, replace it. See [Replacing the IPSI or Tone-Clock Circuit Pack](#).
- g. **Error Type 257:** this error indicates transient communication problems with this circuit pack. This error is not service-affecting and no action is required.
- h. **Error Type 513:** this circuit pack has an on-board hardware failure. Replace the circuit pack using the procedure described in [Replacing the IPSI or Tone-Clock Circuit Pack](#).
- i. **Error Type 769:** this error can be ignored, but look for other errors on this circuit pack.
- j. **Error Type 1025:** this error is not service-affecting, and no action is required.
- k. **Error Type 1538:** the circuit pack was taken out of service because of an excessive rate of uplink messages. Use `test tone-clock location long` to reset the circuit pack and put it back into service. If the command is not successful, replace the circuit pack using the procedure described in [Replacing the IPSI or Tone-Clock Circuit Pack](#). If the alarmed circuit pack is the active Tone-Clock of a duplicated pair, first interchange Tone-Clocks using `set tone-clock location` to avoid a service outage. If the error occurs again within 15 minutes, follow normal escalation procedures.
- l. **Error Type 2049 or 2305:** these errors indicate the loss of one or more clock signals from the reported IPSI or Tone-Clock circuit pack, which was active at the time of the error. The effect of any of these errors is described in the table for Error Type 1. Diagnosis of the problem is the same for all four Error Types, with the exception noted below.
  - 1. Examine the Error Log for errors reported against circuit packs in the same port network, especially TDM-CLK, TONE-BD, and EXP-INTF. Follow the repair or replacement procedures indicated for any such errors found.
  - 2. If the error is not corrected by resolving errors found in step 1, the IPSI or Tone-Clock circuit pack should be replaced. See [Replacing the IPSI or Tone-Clock Circuit Pack](#).

**Note:**

Replacing the circuit pack and retesting it with `test tone-clock` is not adequate to retire this alarm and return the IPSI or Tone-Clock circuit pack to full service; the Clock Health Inquiry test (#46) will continue to fail. Because the ability to generate clocks was considered lost, once any repairs have been made it is necessary to enter `set tone-clock location override`, forcing the circuit pack to become active. If the problem was not corrected, this action may cause a disruption in service for active digital facilities users.

3. If error **2305** or **3848** persists, all clock signals from the indicated board were lost.

If the reported Tone-Clock circuit is in a port network with duplicated Tone-Clocks, the problem may lie with the circuit pack responsible for selecting the active Tone-Clock circuit (the t/c selector, the active EXP-INTF circuit pack).

The t/c selector circuit pack of interest is the one which was active at the time the error was logged. This is the currently active t/c selector, unless there has been an EXP-INTF link switch. In order to determine whether an interchange has occurred since the TONE-BD error, examine the `display initcauses` log for EXP-LNK entries in the error log for expansion link interchanges.

If the t/c selector circuit pack was not replaced as part of the previous step, replace it now. Follow procedures described in [EXP-INTF \(Expansion Interface Circuit Pack\)](#) for the Expansion Interface, or [Reseating and replacing server circuit packs](#) in *Maintenance Procedures (03-300432)*.

4. If the error has not been corrected at this point, there is a problem with the TDM bus within the port network containing the reported Tone-Clock circuit. This may include TDM bus intercarrier cables, bus terminators, bent pins on the backplane, and errors on any circuit pack plugged into the same port network. See [TDM-BUS \(TDM Bus\)](#).

- m. **Error Type 2561:** a Tone-Clock circuit pack, with a different circuit-pack code as required for this system, has been inserted in the port slot as shown in the Error Log. To resolve this error, see [Replacing the IPSI or Tone-Clock Circuit Pack](#) for an appropriate circuit pack code and replace the Tone-Clock circuit pack according to the procedures indicated for this system. The meanings of the Aux Data values are as follows:

|      |                                                                                                                                                        |
|------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1002 | A TN756 Tone-Clock circuit pack (instead of a TN2312) is in a standard- or duplex-reliability system's PN.                                             |
| 1003 | Either a TN741, TN714, TN768, TN780, or TN2182 Tone-Clock circuit pack (instead of a TN2312 IPSI) is in a standard- or duplex-reliability system's PN. |
| 1004 | Either a TN741 or TN714 Tone-Clock circuit pack (instead of a TN768, TN780, TN2182, or TN2312) is in a high- or critical-reliability system's PN.      |
| 1005 | Same as for aux value 1004.                                                                                                                            |

- n. **Error Type 3329:** the system attempted but failed to interchange IPSI or Tone-Clock circuit packs. (This error occurs only in port networks with duplicated Tone-Clocks.) The fault may

lie in the standby Tone-Clock or in the circuit pack that controls selection of the active Tone-Clock (the *t/c selector*). The goal of the following procedure is to ensure that both Tone-Clocks can be interchanged to while either *t/c-selector* circuit pack is active.

1. Examine the Error Log for errors reported against circuit packs in the same port network, paying special attention to TDM-CLK, TONE-BD, DUPINT, SW-CTL, and EXP-INTF. Follow the procedures indicated for any such errors found. After eliminating the above potential problem sources, proceed with the following steps.
2. Determine which circuit pack was controlling the choice of Tone-Clock at the time the error occurred.

The *t/c-selector* circuit pack of interest is the one which was active at the time the error was logged. An EXP-LNK interchange since the time of the error may have made that circuit pack the current standby. Determine whether an interchange affecting the *t/c selector* has occurred since the TONE-BD error. Look for EXP-LNK entries in the error log for PNC interchanges, which would affect the EXP-INTF.

3. If the *t/c selector* has not undergone an interchange since the error occurred, go to the next step. If such an interchange has taken place, interchange back to the formerly active *t/c selector*. Use `set expansion-interface`. If the interchange attempt fails due to other errors, resolve those problems first.
4. Interchange the IPSI or Tone-Clock circuits, using `set tone-clock location`. If the command succeeds, the interchange that previously failed has been accomplished and the problem has been satisfactorily resolved. If it fails, proceed to the next step. You may want to proceed in any case to definitively test all relevant components.
5. Interchange the *t/c selector* using `set expansion-interface`. If errors prevent this interchange, resolve them first.
6. Attempt again to interchange Tone-Clocks with `set tone-clock location`.

If the Tone-Clock interchange failed for both *t/c selectors*, replace the standby Tone-Clock circuit pack which could not be interchanged into and return to this step. (See [Replacing the IPSI or Tone-Clock Circuit Pack](#).) Test the new circuit pack as follows:

- a. Enter `set tone-clock location`.
- b. Enter `set expansion-interface`.
- c. Enter the `set tone-clock location` command again.

If these commands successfully complete, the problem has been resolved.

If these commands successfully complete, the problem has been resolved.

If the IPSI or Tone-Clock circuit packs successfully interchange when one EXP-INTF is active, but not when the other one is, the *t/c-selector* circuit pack on the failing side is suspect.

- d. Replace the EXP-INTF board that is active when the Tone-Clock interchange fails. For the Expansion Interface, see [EXP-INTF \(Expansion Interface Circuit Pack\)](#). Follow procedures in [Reseating and replacing server circuit packs](#) in *Maintenance Procedures (03-300432)*, and “Reliability Systems: A Maintenance Aid” for the DUPINT circuit pack
- e. Make sure the new t/c selector is active and execute `set tone-clock location`.
- f. If both Tone-Clocks can be interchanged into, and interchanges succeed when either t/c selector is active, the problem has been resolved.
- o. **Error Type 3840:** this error is not service-affecting and can be ignored. It indicates that the circuit pack has received a bad control message from the switch.
- p. **Error Type 3848:** the IPSI or Tone-Clock circuit pack had a loss of clock. If error 2305 is also logged, see Note ([k](#)).
- q. **Error Type 3856:** the IPSI or Tone-Clock circuit pack had a loss of clock. If error 2305 is also logged, see Note ([l](#)) for Error Type 2305.
- r. **Error Type 3857 and 3858:** these errors are reported by software when an uplink message is received from the active IPSI’s Archangel firmware. Both Error Types indicate that a loss of one or more clock signals were detected by the archangel, and subsequently restored by changing the CLKSEL lead.

**Note:**

Whenever, the active archangel detects a loss of clock, it will alternate the state of the CLKSEL lead until the lost clock signals are restored.

If the IPSI archangel restores the clock signals by activating the [A] IPSI/Tone-Clock, then Error Type 3857 is reported. If the clock signals are restored by activating the [B] IPSI/Tone-Clock, then Error Type 3858 is reported. A Cold 2 Restart should occur in a port network immediately after Error Type 3857 or 3858 is reported.

**Duplex Reliability** — Since there is only one IPSI in the port network, Error Type 3858 can never occur. When Error Type 3857 occurs, it means the [A] IPSI archangel experienced a loss of clock, but clocking was subsequently restored using the [A] IPSI/Tone-Clock.

**High or Critical Reliability** — If the [B] IPSI is active and the [A] IPSI is healthy when Error Type 3857 is reported, then software attempts to initiate an IPSI interchange to activate the archangel and PKT-INT on the [A] IPSI, thereby ensuring that the active Tone-Clock, PKT-INT, and archangel are all on the same IPSI. If the [A] IPSI is unhealthy, then software initiates a transition to EI-Fallback mode. If the [A] IPSI is active when Error Type 3857 is reported, it means the archangel for the [A] IPSI had to switch the state of the CLKSEL lead more than once to restore the lost clock signals.

When Error Type 3858 is reported, if the [A] IPSI is active and the [B] IPSI is healthy, then software attempts to initiate an IPSI interchange to activate the archangel and PKT-INT on the [B] IPSI. If the [B] IPSI is unhealthy, then software initiates a transition to EI-Fallback mode. If the [B] IPSI is active when Error Type 3858 is reported, it means the archangel for the [B] IPSI had to switch the state of the CLKSEL lead more than once to restore the lost clock signals.

For the high and critical reliability configurations, Error Type 2305 should be logged against TONE-BD for the standby IPSI/Tone-Clock after Error Type 3857 or 3858 is reported.

- s. **Error Type 3872:** an IPSI or Tone-Clock circuit pack had a loss of Data Clocks. This error will impact mainly users on station connected to Digital circuit packs. These users could be with out service. If error 2049 is also logged see Note [\(k\)](#).
- t. **Error Type 3999:** the circuit pack sent a large number of control channel messages to the switch within a short period of time. If Error Type 1538 is also present, then the circuit pack was taken out of service due to hyperactivity. If Error Type 1538 is not present, then the circuit pack has not been taken out of service, but it has generated 50% of the messages necessary to be considered hyperactive. This may be completely normal during heavy traffic periods. However, if this Error Type is logged when the circuit pack is being lightly used, it may indicate a problem with the circuit pack or the equipment attached to it.

## Demand test descriptions and error codes

Investigate tests in the order presented. By clearing errors associated with the first test, errors generated from other tests may also be cleared. Click on the link to see the full description of the test, error codes, and recommended actions.

**For a system with a TN768, TN780, or TN2182 circuit pack:**

| Order of Investigation                                           | Short Test Sequence | Long Test Sequence | Reset Board Sequence | D/ND <sup>1</sup> |
|------------------------------------------------------------------|---------------------|--------------------|----------------------|-------------------|
| <a href="#">SAKI Sanity Test (#53)</a>                           |                     |                    | X                    | D                 |
| <a href="#">Clock Health Inquiry Test (#46)</a>                  | X                   | X                  |                      | ND                |

| <a href="#">TDM Bus Clock Slip Inquiry Test (#149)</a>           | X                   | X                  |                      | ND                |
| <a href="#">TDM Bus Clock PPM Inquiry Test (#150)</a>            | X                   | X                  |                      | ND                |
| <a href="#">TDM Bus Clock Parameter Update Test (#151)</a>       | X                   | X                  |                      | ND                |
| <a href="#">Board Type Check Test (#574)</a>                     | X                   | X                  |                      | ND                |
| <a href="#">Standby Reference Health Check Test (#651) (a)</a>   |                     | X                  |                      | ND                |

1. D = Destructive; ND = Nondestructive

### Notes:

- a. This test runs only on the standby IPSI or Tone-Clock circuit in a port network with duplicated Tone-Clocks (high- or critical-reliability systems). The circuit pack must be a TN780 with firmware version 2 or above.

## TONE-PT (Tone Generator)

| MO Name in Log | Alarm Level | Initial Command to Run                   | Full Name of MO |
|----------------|-------------|------------------------------------------|-----------------|
| TONE-PT        | MAJ<br>MIN  | <code>test tone-clock location</code>    | Tone Generator  |
|                | WRN         | <code>release tone-clock location</code> |                 |

**Note:**

Replacing the IPSI or Tone-Clock circuit pack requires a special procedure which is described in [TONE-BD \(Tone-Clock Circuit Pack\)](#). That section also describes the LED display for this board.

The tone generator resides on the IPSI or Tone-Clock circuit pack and provides all system tones such as dial tone, busy tone, and so on. If an active tone generator fails, its port network may not have tones (see [Tone Generator Transmission Test \(#40\)](#). For instance, a user may go off-hook and hear no dial tone. This problem will affect only users on the same port network where the faulty IPSI or Tone-Clock circuit pack resides. The system will be able to process certain type of calls (that is, internal calls will succeed while outgoing calls will not).

The IPSI or Tone-Clock circuit pack also provides the clocks for the system and can serve as the synchronization reference. Therefore, when resolving alarms, use the [TDM-CLK \(TDM Bus Clock\)](#), [SYNC \(Port Network Synchronization\)](#), and [TONE-BD \(Tone-Clock Circuit Pack\)](#) repair procedures.

See [TONE-BD \(Tone-Clock Circuit Pack\)](#) for a discussion of the relationship of Tone-Clock circuit packs with the various reliability options.

---

## Error log entries and recommended actions

Table 270: TONE-PT Error Log Entries 1 of 2

| Error Type               | Aux Data | Associated Test                    | Alarm Level             | On/Off Board | Recommended Action                                |
|--------------------------|----------|------------------------------------|-------------------------|--------------|---------------------------------------------------|
| 0 ( <a href="#">a</a> )  | 0        | Any                                | Any                     | Any          | <code>test tone-clock location<sup>1</sup></code> |
| 1 ( <a href="#">b</a> )  | 17664    | Tone Generator Audit/ Update (#41) | MAJ<br>MIN <sup>2</sup> | ON           | <code>test tone-clock location r 2</code>         |
| 18 ( <a href="#">c</a> ) | 0        | busyout tone-clock location        | WRN                     | OFF          | <code>release tone-clock location</code>          |
|                          |          |                                    |                         |              | <i>1 of 2</i>                                     |

**Table 270: TONE-PT Error Log Entries 2 of 2**

| Error Type | Aux Data | Associated Test                        | Alarm Level             | On/Off Board | Recommended Action                         |
|------------|----------|----------------------------------------|-------------------------|--------------|--------------------------------------------|
| 130 (d)    |          |                                        | MIN                     | ON           | <code>test tone-clock location</code>      |
| 257 (e)(g) | 17667    |                                        | MIN                     | ON           |                                            |
| 513 (f)(g) | 17666    | Tone Generator Audit/ Update (#41)     | MIN                     | ON           | <code>test tone-clock location r 3</code>  |
| 769 (h)    |          | Tone Generator Transmission Test (#40) | MAJ<br>MIN <sub>2</sub> | ON           | <code>test tone-clock location long</code> |
| 1025 (i)   |          | Tone Generator Crosstalk (#90)         | MAJ<br>MIN <sub>2</sub> | ON           | <code>test tone-clock location long</code> |
| 1281 (j)   | Any      | Tone Generator Audit/ Update (#41)     | MIN                     | OFF          | <code>test tone-clock location r 3</code>  |
|            |          |                                        |                         |              | <i>2 of 2</i>                              |

1. IPSI circuit packs require the *location* qualifier; Tone-Clock circuit packs do not.

2. MAJOR alarm if the alarmed IPSI or Tone-Clock circuit pack is not duplicated; MINOR if it is duplicated within the same PN.

Notes:

- a. **Error Type 0:** run the short test sequence first. If every test passes, run the long test sequence. Refer to each appropriate test's description, and follow its recommended procedures.
- b. **Error Type 1:** A failure in the tone generation facility on the indicated circuit pack has been detected. Replace the circuit pack. See [Replacing the IPSI or Tone-Clock Circuit Pack](#).
- c. **Error Type 18:** the IPSI or Tone-Clock circuit pack has been made unavailable using `busyout tone-clock location`. It only applies to systems which have the high- or critical-reliability option administered, because only a standby Tone-Clock circuit may be made busy by that command. To resolve this error, execute `release tone-clock location` for the alarmed circuit pack.

**Note:**

IPSI circuit packs require the *location* qualifier; Tone-Clock circuit packs do not.

- d. **Error Type 130:** the circuit pack has been removed or has been insane for more than 11-minutes. To clear the error, reinsert or replace the circuit pack.
- e. **Error Type 257:** the tone generation facility is having problems verifying that tones have been connected as requested
- f. **Error Type 513:** The tone generation facility may or may not be able to generate tones.

- g. **Error Type 257 and 513:** infrequent errors, at a rate which does not bring up an alarm, probably do not affect service, unless there are customer complaints of no tones, or incorrect tones which can not be explained in any other way. However, if an alarm is raised because this error is being repeatedly logged, then the circuit pack should be replaced. See [Replacing the IPSI or Tone-Clock Circuit Pack](#).
- h. **Error Type 769:** The tone generator transmission test failed. See the description for Test #40.
- i. **Error Type 1025:** The tone generator crosstalk test failed. See the description for Test #90.
- j. **Error Type 1281:** **tone-generation** administration requires a TN780 or TN2182 Tone-Clock, or a TN2312 IPSI circuit pack, but the existing Tone-Clock circuit does not provide the needed functionality. The Base Tone Generation Set on page 1 or the custom tones beginning on page 2 of the **tone-generation** screen may have values not supported by the existing Tone-Clock.

Error Type 1281 indicates that the **tone-generation** screen has custom tones translated and that the alarmed tone board does not support the customized tones. TN768 tone boards do not support any customized tones. TN780 tone boards support up to 6 of the following customized frequencies/levels only:

|                           |                          |
|---------------------------|--------------------------|
| Silence                   | 404Hz at 11.0 dB         |
| 350Hz at 17.25 dB         | 404Hz at 16.0 dB         |
| 425Hz at 4.0 dB           | 480Hz + 620Hz at 24.0 dB |
| 425Hz at 11.0 dB          | 404Hz + 425Hz at 11.0 dB |
| 425Hz at 17.25 dB         | 375Hz + 425Hz at 15.0 dB |
| 440Hz at 17.25 dB         | 404Hz + 450Hz at 11.0 dB |
| 350Hz + 425Hz at 4.0 dB   | 1000Hz at 0.0 dB         |
| 350Hz + 440Hz at 13.75 dB | 1000Hz at +3.0 dB        |
| 480Hz at 17.25 dB         | 525Hz at 11.0 dB         |
| 620Hz at 17.25 dB         | 1400Hz at 11.0 dB        |
| 440Hz + 480Hz at 19.0 dB  |                          |

## Demand test descriptions and error codes

Investigate tests in the order presented. By clearing errors associated with the first test, errors generated from other tests may also be cleared. Click on the link to see the full description of the test, error codes, and recommended actions.

| Order of Investigation                                           | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|------------------------------------------------------------------|---------------------|--------------------|-------------------|
| <a href="#">SAKI Sanity Test (#53)</a>                           |                     | X                  | D                 |

| <a href="#">Board Type Check Test (#574)</a>                     | X                   | X                  | ND                |
| <a href="#">Standby Reference Health Check Test (#651)</a>       |                     | X                  | ND                |

1. D = Destructive; ND = Nondestructive

## TR-LN-BD (Analog Trunk/Line Board)

See [XXX-BD \(Common Port Circuit Pack/Media Module\)](#).

## TSC-ADM (Administered Temporary Signaling Connections)

| MO Name in Log | Alarm Level | Initial Command to Run | Full Name of MO                              |
|----------------|-------------|------------------------|----------------------------------------------|
| TSC-ADM        | none        | none                   | Administered Temporary Signaling Connections |

No alarms are generated for Administered Temporary Signaling Connections (TSC-ADM, also called ADM TSCs).

Administered temporary signaling connections (TSC) provide a path through ISDN-PRI networks for supplementary D-channel messages. ISDN-PRI applications such as the Distributed Communications System (DCS) use temporary signaling connections to exchange user information across an ISDN-PRI network. What makes Administered TSCs unique is that these particular TSCs stay active for an extended period of time, similar to a permanent data connection. These ADM TSCs are used for DCS features that require Non-Call Associated (NCA) TSCs, and the ADM TSC provides the logical channel function in a DCS network.

An NCA TSC is a virtual connection established within a D-channel without associating any B-channel connections. The connection provides user-to-user service by exchanging USER INFORMATION messages without associated B-channel connections.

An Administered TSC is a special NCA TSC defined for the DCS over the ISDN-PRI D-channel. The ADM TSC has an administratively defined endpoint and is established for an extended period of time.

There are two types of ADM TSCs:

- 1 Permanent: these are established by the originating PBX (near-end ADM TSC) or by the terminating PBX (far-end ADM TSC). Once these ADM TSCs are established, they remain active.
- 1 As-Needed: these are established only when needed.

ADM TSC maintenance provides a strategy to verify that a far end can respond to an ISDN-PRI USER INFORMATION TSC heartbeat message, thereby indicating that user-user signaling is functioning. In addition, maintenance can retrieve the status of the ADM TSC's connection state.

Since ADM TSCs are administered on a per signaling-group basis, the health of an ADM TSC also depends on the state of the D-channel or D-channel pair administered per signaling group. See [ISDN-SGR \(ISDN-PRI Signaling Group\)](#) documentation for details on ISDN-PRI NFAS and D-channel backup maintenance.

The two administration commands for ADM TSCs are as follows:

- 1 `add signaling-group number`
- 1 `change signaling-group number`

The two maintenance commands for ADM TSCs are:

```

1 test tsc-administered signaling-group-number [/tsc-index]
1 status tsc-administered signaling-group-number [/tsc-index]

```

---

## Error log entries and recommended actions

Table 271: TSC-ADM Error Log Entries

| Error Type       | Aux Data    | Associated Test       | Alarm Level | On/Off Board | Recommended Action |
|------------------|-------------|-----------------------|-------------|--------------|--------------------|
| 3840 to 3967 (a) | tsc index # | test tsc-administered |             |              |                    |

Note:

a. **Error Types 3840 - 3967:** there is no test to clear these Error Types.

Any of these errors indicates that a TSC Heartbeat Inquiry test was run on an active far-end Administered TSC from the switch. Upon receiving the heartbeat message, the network communicated that the call was unable to complete. As a result, the error was logged.

1. Check the signaling group status of the D-channel or D-channel pair using `status signaling-group grp#` for the Administered TSC.
2. Check the status of the Administered TSC using `status tsc-administered`.
3. Also check the administration of the Administered TSC on the switch.

This error may only be affecting service for some DCS customers. Upon receipt of this error condition, the switch will tear down and re-establish the ADM TSC within 20 minutes.

The **Port** field in the error log contains the signaling group number for TSC-ADM errors.

---

## Demand test descriptions and error codes

| Order of Investigation                            | Short Test Sequence | Long Test Sequence | D/ND           |
|---------------------------------------------------|---------------------|--------------------|----------------|
| <a href="#">TSC Heartbeat Inquiry Test (#604)</a> |                     |                    | Nondestructive |

## TTR-LEV (TTR Level)

| MO Name | Alarm Level       | Initial Command to Run                                 | Full Name of MO |
|---------|-------------------|--------------------------------------------------------|-----------------|
| TTR-LEV | MAJ<br>MIN<br>WRN | See the <a href="#">Repair Procedure for TTR-LEV</a> . | TTR Level       |

TN748 and TN420 Tone Detector circuit packs and TN744 Call Classifier circuit packs provide tone receivers for detecting various types of signaling tones. These circuit packs are shared resources that serve every user of the PBX. This discussion uses the following terms and abbreviations (note that the Maintenance-Related System-Parameters screen uses different names than the alarm and error logs):

| Type of Tone Receiver                  | MO       | Also Known As                            | Location          |
|----------------------------------------|----------|------------------------------------------|-------------------|
| Dual-Tone Multifrequency Tone Receiver | DTMR-PT  | Touch-Tone Receiver (TTR)                | 4 per TN420/TN748 |
| General-Purpose Tone Detector          | GPTD-PT  | Call-Progress Tone Receiver (CPTR)       | 2 per TN420/TN748 |
| Call Classifier                        | CLSFY-PT | Call-Classification Tone Receiver (CCTR) | 8 per TN744       |

TN748s and TN420s each have 4 DTMR-PTs and 2 GPTD-PTs. DTMR-PTs interpret dual-tone multifrequency (DTMF) calling signals and translate them into logical digits 0 through 9, \*, and #. GPTD-PTs detect call-progress tones, modem answer tones, and transmission test tones.

TN744 Call Classifier circuit packs have 8 CLSFY-PTs. These ports detect DTMF tones and classify network and MFC (multifrequency compelled) signaling tones. (That is, CLSFY-PTs can function as DTMR-PTs or GPTD-PTs, and have other additional capacities).

When a user goes off-hook to place a call, dial tone is returned to the user, indicating that a tone detector is connected and ready to receive and interpret tones. The tone detector is in use until the total number of digits needed is collected or until a time-out occurs. If every tone detector in the system is being used simultaneously, the next user to go off-hook will not receive dial tone until a tone detector becomes available. It is therefore necessary to have a sufficient number of tone detectors in the system to prevent delays in receiving dial tone. The `list measurements tone-receiver` command shows the level of tone detector usage.

In order to prevent dial-tone delays and other shortcomings in system performance, threshold levels for the 3 types of tone receivers are administered on the System-Parameters Maintenance screen. Whenever the number of tone receivers in service falls below the administered threshold for that type of tone receiver, an alarm is logged against the TTR Level MO. At this point, the system is operating properly, but call processing capacity is reduced. Another alarm is logged if the number falls to zero. At this point, system operation is severely compromised.

Typical causes of these events are:

1. The threshold for GPTD-PTs or DTMR-PTs is administered incorrectly on the Maintenance-Related System-Parameters screen.
2. Too many GPTD-PTs, DTMR-PTs, or CLSFY-PTs have been taken out of service, possibly by maintenance software or a demand busyout.
3. A tone detector circuit pack has been removed or suffered a fatal failure, resulting in the loss of all its ports.
4. The system has an insufficient number of TN748/TN744/TN420 circuit packs.

---

## Repair Procedure for TTR-LEV

To resolve a TTR-LEV alarm:

1. Enter **display errors** and use the TTR-LEV Error Log Table to determine which type of tone receiver has fallen below its threshold.
2. Enter **change system-parameters maintenance**, and check the administered value. On the screen, TTR represents DTMR-PTs, CPTR represents GPTD-PTs, and Call Classifier represents CLSFY-PTs. If the threshold value is set too high, change it to a lower value and wait a minute for the alarm to clear.

To determine the correct thresholds, first find the total number of TN478/TN420 Tone Detector and TN744 Call Classifier circuit packs in the system using **list configuration**. Then calculate the total number of tone receiver ports of each type. Each Tone Detector circuit pack has 4 TTR (DTMR) ports and 2 CPTR (GPTD) ports. Each TN744 Call Classifier circuit pack has 8 Call Classifier (CLSFY-PT) ports.

For each type of tone receiver, if the total number of ports installed in the system is less than the administered threshold, either add more circuit packs to the system or reduce the threshold to match the number already in the system. If the TTR Level alarm is still present, proceed to Step 3.

3. Enter **display errors** for Error Type 18 and look for GPTD-PTs, DTMR-PTs, or CLSFY-PTs that have been busied out.

For each of the busied-out ports:

- a. Determine why the port was busied out.
- b. If the port can be placed back into service, test the port using **test port location**.
- c. If every test passes, enter **release port** and wait 1 minute for the TTR Level alarm to clear.

If this does not clear the TTR Level alarm, proceed to Step 4.

4. Enter `display alarms` and determine the location of the circuit pack with the alarmed GPTD-PT, DTMR-PT, or GPTD-PT.

Run `test board location 1 r 3` for that circuit pack.

If this does not clear the TTR Level alarm, replace the Tone Detector or Call Classifier circuit pack with the alarmed GPTD-PT, DTMR-PT, or CLSFY-PT.

---

## Error log entries and recommended actions

**Table 272: TTR-LEV Error Log Entries**

| Error Type | Aux Data | Associated Test | Alarm Level                | On/Off Board | Recommended Action |
|------------|----------|-----------------|----------------------------|--------------|--------------------|
| 1 (a)      | 1        |                 |                            |              |                    |
| 2 (b)      | 2        |                 | WRN<br>(See message below) | OFF          |                    |
| 3 (c)      | 3        |                 |                            |              |                    |
| 4 (d)      | 4        |                 | WRN                        | OFF          |                    |
| 5 (e)      | 5        |                 |                            |              |                    |
| 6 (f)      | 6        |                 | WRN                        | OFF          |                    |
| 7 (g)      | 7        |                 | MAJ                        | OFF          |                    |
| 8 (h)      | 8        |                 | MIN                        | OFF          |                    |
| 9 (i)      | 9        |                 | MIN                        | OFF          |                    |

The TTR-LEV Alarm is upgraded to MAJOR if the Base Tone Generator is set to 12 (France).

Notes:

- a. **Error Type 1:** does not indicate a current error condition. It indicates that the number of DTMR ports in service was below the administered threshold, but is now equal to or greater than the threshold. These errors are typically generated during boot time or other transitional states when the ports are being brought into service.
- b. **Error Type 2:** the total number of DTMR ports currently in service is below the administered threshold. To clear the alarm, see [Repair Procedure for TTR-LEV](#).
- c. **Error Type 3:** does not indicate a current error condition. It indicates that the number of GPTD ports in service was below the administered threshold, but is now equal to or greater than the threshold. These errors are typically generated during boot time or other transitional states when the ports are being brought into service.

- d. **Error Type 4:** the total number of GPTD ports currently in service is below the administered threshold. To clear the alarm, see [Repair Procedure for TTR-LEV](#).
- e. **Error Type 5:** does not indicate a current error condition. It indicates that the number of Call Classifier ports (CLSFY-PT) service was below the administered threshold, but is now equal to or greater than the threshold. These errors are typically generated during boot time or other transitional states when the ports are being brought into service.
- f. **Error Type 6:** the total number of Call Classifier ports (CLSFY-PT) currently in service is below the administered threshold. To clear the alarm, see [Repair Procedure for TTR-LEV](#).
- g. **Error Type 7:** there are currently no DTMR ports in service. To clear the alarm, see [Repair Procedure for TTR-LEV](#).
- h. **Error Type 8:** there are currently no GPTD ports in service. To clear the alarm, see [Repair Procedure for TTR-LEV](#).
- i. **Error Type 9:** there are currently no Call Classifier ports (CLSFY-PT) in service. To clear the alarm, see [Repair Procedure for TTR-LEV](#).

## UDS1-BD (UDS1 Interface Circuit Pack)

| MO Name in Log | Alarm Level | Initial Command to Run             | Full Name of MO             |
|----------------|-------------|------------------------------------|-----------------------------|
| UDS1-BD        | MAJ<br>MIN  | <code>test board location 1</code> | UDS1 Interface Circuit Pack |
|                | WRN         | <code>test board location</code>   |                             |

The UDS1 Interface circuit pack provides an interface to the DS1 facility.

The maintenance strategy for the TN464 UDS1 Interface circuit pack (UDS1-BD) is very similar to the maintenance strategy for the TN767 DS1 Interface circuit pack (DS1-BD). The same commands are used for administering and testing the boards. The differences in maintenance strategy between the boards are due to the UDS1 circuit pack's direct interface to the Packet bus which is used for ISDN-PRI signaling (ISDN-PLK). While both the TN464 and TN767 can support ISDN-PRI B-channels, ISDN-PRI D-channel signaling applications require a TN464 UDS1 circuit pack. See the following table for a list of USD1 Interface circuit packs:

| Circuit Pack Code       | 24-channel | 32-channel | Tie Trunk Signaling | CO Trunk Signaling | DID Trunk Signaling | OPS Line Signaling |
|-------------------------|------------|------------|---------------------|--------------------|---------------------|--------------------|
| TN2242                  | X          | X          | X                   |                    |                     |                    |
| TN464C/D/E/F<br>TN464GP | X          | X          | X                   | X                  | X                   | X<br>(24-chl only) |
| TN2464                  | X          | X          | X                   | X                  | X                   | X                  |

**Note:**

For information about other DS1 circuit packs, see [DS1-BD \(DS1 Interface Circuit Pack\)](#).

The UDS1 maintenance strategy includes logging inline errors reported by the UDS1 Interface circuit pack, running tests for error diagnosis and recovery, and raising or clearing maintenance alarms.

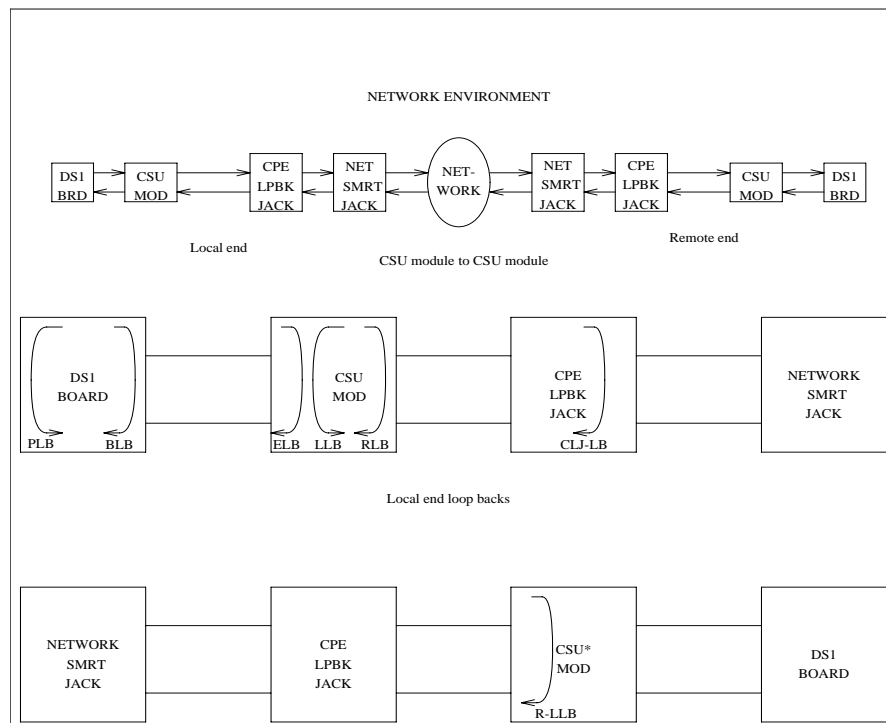

The TN464F or later circuit pack combined with an 120A1 CSU module forms an Enhanced Integrated CSU. The 120A1 CSU module, when combined with the functionality provided by the TN464F hardware and firmware, and switch software, provides functionality equivalent to an external stand-alone ESF T1 CSU. The 120A1 CSU module connects to the TN464F circuit pack on the I/O connector panel on the back of the port carrier. The CSU module thus becomes an integrated part of the system. Throughout the document, the term 120A1 will mean a 120A1 or higher suffix CSU module.

The Enhanced Integrated CSU is for use in the United States of America with 1.544-Mbps DS1 service. For further details on the 120A1 CSU module refer to *Installing and Operating a 120A Channel Service Unit with Avaya Communication Manager*.

The UDS1-BD and 120A1 CSU module support on-demand loopback tests that assist in the detection of faults between the UDS1-BD circuit pack and the CSU module, between the Integrated CSU and the optional Customer Premises Loopback Jack, or between the Integrated CSU and remote CSU.

[Figure 92: High Level Overview Of Loopback Points](#) gives a high level overview of the loopback points.

**Figure 92: High Level Overview Of Loopback Points**

The following list of acronym definitions are for the [Figure 92: High Level Overview Of Loopback Points](#):

- 1 PLB = Payload Loopback
- 1 BLB = Board Loopback
- 1 ELB = Equipment Loopback
- 1 LLB = Line Loopback
- 1 RLB = Repeater Loopback
- 1 CLJ = CPE Loopback Jack
- 1 R-LLB = Remote Line Loopback

- 1 SMRT = Smart Jack
  - 1 LPBK = Loopback
- 

---

## TN464GP/TN2464BP UDS1 Circuit Packs with Echo Cancellation

The TN464GP and TN2464BP UDS1 circuit packs feature an integrated echo canceller. Echo cancellation is a Software Right-To-Use feature that can be turned on as needed. Echo cancellation supports channels carrying voice and is not intended for channels that support data. The TN464GP/TN2464BP have the capability to detect modem tone and turn off echo cancellation accordingly for the duration of a data call. Echo cancellation on the TN464GP/TN2464BP is administrable per channel. The echo cancellation circuitry on a given TN464GP/TN2464BP is driven by administrable parameters.

The TN464GP/TN2464BP circuit packs are intended for use with ATM, IP, wideband, or other complex services which are likely to have problems with echo.

Echo cancellation on a TN464GP/TN2464BP is a right-to-use feature that is activated by means of the License File. Echo cancellation is enabled on the System-Parameters Customer-Options screen. The **Maximum Number of DS1 Boards with Echo Cancellation** field on the System-Parameters Customer-Options screen indicates the number of DS1 boards on which echo cancellation is activated for a specific customer.

The DS1 Circuit Pack screen for the TN464GP/TN2464BP circuit packs has fields to support echo cancellation: **Echo Cancellation**, **EC Direction**, and **EC Configuration**. The **Echo Cancellation** field appears when the Echo Cancellation feature is activated on the System-Parameters Customer Options screen. The **EC Direction** and **EC Configuration** fields appear when the **DS1 Echo Cancellation** field is enabled.

- 1 **EC Direction** determines the direction from which echo will be eliminated, either inward or outward.
- 1 **EC Configuration** is the set of parameters used when cancelling echo. This information is stored in firmware on the UDS1 circuit pack.

Echo cancellation is turned on or off on a per trunk-group basis using **change trunk-group**. If the TRUNK GROUP field, **DS1 Echo Cancellation** is **y**, echo cancellation is applied to every TN464GP/TN2464BP trunk member in that trunk group. The echo cancellation parameters used for a given trunk member are determined by the Echo Cancellation Configuration Number administered on the DS1 Circuit Pack screen for that specific trunk's board.

### Note:

It is not necessary to busyout a port or trunk group to change the DS1 Echo Cancellation field on the Trunk Group screen. However, the modified setting does not take effect until one of the following occurs:

- 1 Port is busied out/released

- 1 Trunk Group is busied out/released
- 1 Test trunk group is executed
- 1 Periodic maintenance runs

Echo cancellation on the TN464GP/TN2464BP is selectable per channel, even though it is administrable on a per trunk-group basis. For example, if all but two ports on a TN464GP/ TN2464BP need to have echo cancellation applied, those two ports must be put in a trunk group where the **DS1 Echo Cancellation** field is **n**. The remaining ports are in a trunk group(s) where the **DS1 Echo Cancellation** field is **y**. A user can cancel echo coming from the network (far-end echo) or coming from the switch (near-end echo).

---

## The TN464 UDS1 Circuit Pack

The TN464C, D, E, F, and GP Universal DS1 Interface circuit packs provide an interface to the DS1 facility, and are designed to support 24 DS0 channels on a 1.544-Mbps DS1 link, or 32 DS0 channels on a 2.048-Mbps link. The DS0 channels can be administered as trunks to other switches, lines to off-premises stations, ports to line-side PRI terminating devices, or ports to other line-side non-PRI terminating devices. (DS0 channels on TN464/Bs can only be administered as trunks to other switches.) For more information about how TN464 ports can be used, see the following MOs:

- 1 [ISDN-SGR \(ISDN-PRI Signaling Group\)](#)
- 1 [ISDN-TRK \(DS1 ISDN Trunk\)](#)
- 1 [ISDN-PLK \(ISDN-PRI Signaling Link Port\)](#)
- 1 [\\_PE \(Processor Ethernet\) Alarms](#)
- 1 [TIE-DS1 \(DS1 Tie Trunk\)](#)
- 1 [CO-DS1 \(DS1 CO Trunk\)](#)
- 1 [DID-DS1 \(Direct Inward Dial Trunk\)](#)
- 1 [OPS-LINE \(DS1 Off-Premises Station Line\)](#)
- 1 [WAE-PORT \(Wideband Access Endpoint Port\)](#)

**Note:**

For information about other DS1 circuit packs, see [DS1-BD \(DS1 Interface Circuit Pack\)](#).

**Note:**

The TN464GP provides Echo Cancellation, and in addition, the TN464GP firmware may be updated using the firmware download feature.

Throughout this Maintenance Object (UDS1-BD), the term TN464 will mean any TN464C or higher suffix UDS1 circuit pack. If part of this section refers to a specific suffix TN464 board, it will be noted as such.

TN464 circuit packs support the following:

- 1 Digital Tie, CO, and DID trunks
- 1 DS1 off-premises (OPS) lines
- 1 Narrowband and wideband access endpoint ports
- 1 ISDN-PRI trunks and accompanying signaling channel
- 1 PRI endpoint ports (PE-BCHL) and accompanying signaling channel

The TN464 supports digital Tie, CO, and DID trunks, and OPS lines. On-board firmware performs call control signaling for the Tie, CO and DID trunks and OPS lines. ISDN-PRI trunk and PRI-endpoint signaling (Q.921, Q.931) is received and generated by system software and is transmitted on a system link through the TN1655 Packet Interface and packet bus to the UDS1 where it is placed on the D channel. Signaling over the DS1 link has to be synchronized between the transmitting and receiving ends to ensure error-free communication. See [SYNC \(Port Network Synchronization\)](#) for details.

Each trunk, line, or endpoint has its own maintenance strategy, but all depend on the health of the UDS1 Interface circuit pack. See the following Maintenance Objects for details:

[TIE-DS1 \(DS1 Tie Trunk\)](#)

[CO-DS1 \(DS1 CO Trunk\)](#)

[DID-DS1 \(Direct Inward Dial Trunk\)](#)

[OPS-LINE \(DS1 Off-Premises Station Line\)](#)

[ISDN-TRK \(DS1 ISDN Trunk\)](#)

[ISDN-PLK \(ISDN-PRI Signaling Link Port\)](#)

[ISDN-SGR \(ISDN-PRI Signaling Group\),](#)

[WAE-PORT \(Wideband Access Endpoint Port\)](#)

[\\_PE \(Processor Ethernet\) Alarms.](#)

---

## Circuit Pack Administration and Options

The DS1 configuration for each circuit pack is administered on the DS1 Circuit Pack screen. **Bit Rate** is set to 1.544 Mbps for 24-channel systems, and 2.048 Mbps for 32-channel systems. **Country Protocol** is used to drive layer-3 protocol decisions based on PRI specifications for a given country (not those related to specific features). Different UDS1 circuit packs may be administered with different Country Protocols, allowing the switch to act as a gateway between two incompatible ISDN-PRI implementations (for example, between two different countries). US systems use country protocol 1.

Set **Near-End CSU Type** to **other** for no CSU installed or for an external CSU such as an ESF T1 CSU, or set to **integrated** for the 120A1 CSU module or the 401A T1 sync splitter. Setting the field to **integrated** causes additional fields to appear for administering the Enhanced Integrated CSU module. Set **E1 Sync-Splitter** to **y** if a 402A or 403A E1 sync splitter is used to provide timing to an ATM switch. Set **Echo Cancellation** to **y** if the echo cancellation right-to-use feature is enabled and the TN464GP/TN2464BP or higher suffix board is to supply echo cancellation.

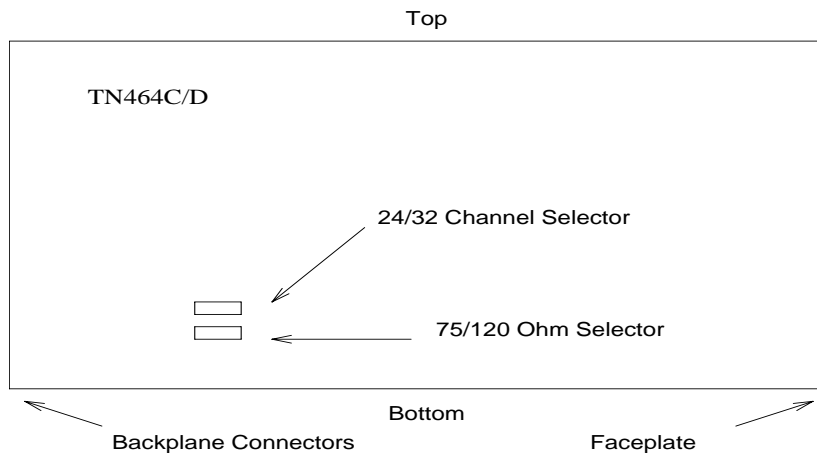

**Note:**

Set the **Echo Cancellation Plan** on the **EC Configuration** field of the DS1 Circuit Pack screen. Note that Plan 1 uses a 96-ms echo tail and introduces 6dB of loss for additional cancellation.

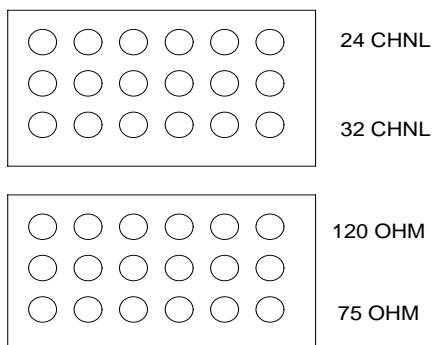

In addition, other fields define such parameters as framing modes, line coding, companding mode and so on. For further details refer to *Installing and Operating a 120A Channel Service Unit with Avaya Communication Manager*.

Two option jumpers located on the side of the TN464C/D circuit pack must be installed correctly. The figures on the following page show how to configure the circuit pack for 24- or 32-channel DS1, and for 75\*W (coaxial) or 120\*W trunk connections. The channel selection must match the parameters administered on the corresponding DS1 Circuit Pack screen. (US applications use 24 channels.)

**Figure 93: TN464C/D DS1 Option Jumpers**

**Figure 94: TN464C/D DS1 Option Jumpers (cont'd)**

Insert the jumpers into the blocks so as to join the center row of pins and the row designating the desired options.

The option switch located on the component side of the TN464E/F circuit pack must be set correctly. [Figure 95: TN464E/F DS1 Option switches](#) shows how to configure the circuit pack for 24-channel or 32-channel DS1. The channel selection must match the parameters administered on the corresponding DS1 Circuit Pack screen. (US applications use 24 channels.)

**Figure 95: TN464E/F DS1 Option switches**

## Error log entries and recommended actions

**Table 273: UDS1-BD Error Log Entries 1 of 5**

| Error Type     | Aux Data | Associated Test                           | Alarm Level             | On/Off Board | Recommended Action            |

|                   |                 |                                    |                                |                     | <b>4 of 5</b>                  |

**Table 273: UDS1-BD Error Log Entries 5 of 5**

| <b>Error Type</b> | <b>Aux Data</b> | <b>Associated Test</b> | <b>Alarm Level</b> | <b>On/Off Board</b> | <b>Recommended Action</b> |
|-------------------|-----------------|------------------------|--------------------|---------------------|---------------------------|
| 3999 (af)         | Any             | None                   |                    |                     |                           |
|                   |                 |                        |                    |                     | <b>5 of 5</b>             |

1. Run the short test sequence first. If every test passes, run the long test sequence. Refer to the appropriate test's description, and follow its recommended procedures.
2. If ports are assigned to the circuit pack, then a minor alarm is raised. If no ports are assigned to the circuit pack, then a warning alarm is raised. The alarm is raised after the circuit pack has been missing for a period of 15 minutes. Warning alarms are also raised against any ports administered on the circuit pack.
3. Minor alarms on this MO may be downgraded to Warning based on values on the `set options` screen.
4. Major alarms on this MO may be downgraded to minor or warning alarms based on values set on the `set options` screen.

**Notes:**

- a. **Error Type 1:** indicates that the circuit pack has stopped functioning or is not fully administered. The alarm is logged about 15 minutes after the circuit pack has been removed or 11 minutes after the SAKI test (#53) fails.

To be fully administered, a UDS1 circuit pack must meet all of the following conditions:

- 1 Have an entry in the circuit plan using `change circuit-pack`
- 1 Be administered using `add ds1 location`
- 1 Be physically inserted into the correct slot

If the circuit pack has an entry in the circuit plan and either of the other conditions are not met, a MINOR alarm is logged. To resolve the error:

1. Make sure that all conditions for administration are met and that a functioning UDS1 circuit pack is inserted in the correct slot.

or

2. Completely remove the UDS1-BD from the system:
  - a. Remove any administered DS1 trunks, access endpoints or PRI endpoints associated with the circuit pack from their trunk groups.
  - b. Execute `remove ds1 location` and `change circuit-pack location`.

If every administration condition is met for this circuit pack and the red LED is still on, follow the instructions for LED alarms without Alarm Log entry or with Error Type 1 in *LED Descriptions for Avaya Aura™ Communication Manager Hardware Components (03-602804)*

- b. **Error Type 18:** the UDS1 Interface circuit pack was busied out by `busyout board location`.

c. **Error Type 23:** the UDS1-BD circuit pack is not completely administered. To be fully administered, the UDS1 circuit pack must:

- 1 Have an entry in the circuit plan using `change circuit-pack`
- 1 Be administered using `add ds1 location`
- 1 Be physically inserted into the correct slot

A DS1 (UDS1-BD and DS1-BD) differs from most circuit packs in that inserting the circuit pack into the switch is not enough to make the board usable. It must also be administered with `add ds1`.

d. **Error Type 125: (no Aux Data):** an incorrect circuit pack is inserted in the slot where the USD1 circuit pack is logically administered. To resolve this problem, do one of the following:

- 1 Remove the incorrect circuit pack, and insert the correct logically administered circuit pack.
- 1 Use `change circuit-pack` to re-administer this slot to match the circuit pack inserted.

**Aux Data 3:** the 24-/32-channel option jumper setting on the circuit pack does not match the option set on the DS1 Circuit Pack administration screen. The circuit pack must be physically removed to see the setting of the jumper.

e. **Error Type 257:** associated with the Common Port Circuit Pack Maintenance test. See [XXX-BD \(Common Port Circuit Pack/Media Module\)](#) for details.

f. **Error Type 513:** the UDS1 Interface circuit pack has detected a transient hardware problem. The value in the Aux Data field indicates the type of hardware problem:

| Aux Data | Problem              |
|----------|----------------------|
| 4352     | External RAM failure |
| 4353     | Internal RAM failure |
| 4355     | Internal ROM failure |

If the UDS1 board detects only one of these hardware problems, then the error will disappear when none of these faults are detected for 10 minutes. If the same Aux Data value is logged more than once in a 24-hour period, the circuit pack should be replaced.

g. **Error Type 514:** LAN External RAM Error. This error occurs when there is a hardware fault in the external RAM. The RAM is used for message buffering to and from the Packet bus. This error should not occur frequently. If it does (10 times within 30 minutes), the circuit pack should be replaced.

- h. **Error Type 769:** transmit FIFO Underflow Error. This error occurs when the circuit pack cannot find the “end of frame” bit when transmitting a frame to the Packet bus. An alarm is raised if this error occurs three times within 10 minutes. Clear the alarm using the following commands: **busyout board location, reset board location, test board location long, release board location**. If the error recurs within 10 minutes, replace the circuit pack.
- i. **Error Type 770:** unable to Write LAN Translation RAM Error. This error occurs when a call is aborted because there are no available translation RAM locations for the call connection attempt. An alarm is raised if this error occurs two times within 10 minutes. Clear the alarm using the following commands: **busyout board location, reset board location, test board location long, release board location**. If the error recurs within 10 minutes, replace the circuit pack.
- j. **Error Type 1300:** CSU module/T1 sync splitter missing or E1 synchronization splitter (E1SS) missing.

**CSU module/T1 sync splitter missing:** The **Near-End CSU Type** field on the **add ds1** screen is **integrated** but the 120A1 CSU module or the 401A T1 sync splitter is not physically connected (or is improperly connected) to the UDS1 board on the back of the port carrier.

If using the 120A1 CSU module or the 401A T1 sync splitter, plug (or replug) the CSU module/T1 sync splitter into the UDS1 circuit pack’s connector on the I/O connector panel on back of the carrier. Otherwise, set the **Near-End CSU Type** field using the **change ds1** screen to **other**.

If this error remains after plugging the CSU module/T1 sync splitter into the board’s connector, there could be a problem with the I/O connector panel.

**E1 synchronization splitter missing:** The **E1 Sync-Splitter** field on the **add ds1** screen is **y**, but the 402A or 403A E1 synchronization splitter is not physically connected (or is improperly connected) to the UDS1 board on the back of the port carrier.

If using the 402A or 403A E1 synchronization splitter, plug (or replug) the E1SS into the UDS1 circuit pack’s connector on the I/O connector panel on back of the carrier. Otherwise, set the **E1 Sync-Splitter** field using the **change ds1** screen to **n**.

If this error remains after plugging the E1SS into the board’s connector, there could be a problem with the I/O connector panel.

- k. **Error Type 1301:** CSU module/T1 sync splitter not expected or E1 synchronization splitter not expected.

**CSU Module/T1 Sync Splitter not expected:** The 120A1 CSU module or the 401A T1 sync splitter is physically connected to the UDS1 board on the back of the port carrier, but the **Near-End CSU Type** field on the **add ds1** screen is not set to **integrated**.

If the 120A1 CSU module or the 401A T1 sync splitter is to be used, use **change ds1** to set the **Near-End CSU Type** field to **integrated**. Otherwise, physically remove the 120A1 CSU module or the 401A T1 sync splitter from the back of the port carrier.

**E1 synchronization splitter not expected:** The 402A or 403A E1 synchronization splitter is physically connected to the UDS1 board on the back of the port carrier, but the **E1 Sync-Splitter** field on the `add ds1` screen is not set to **y**.

If the 402A or 403A E1 synchronization splitter is to be used, use `change ds1` to set the **E1 Sync-Splitter** field to **y**. Otherwise, physically remove the 402A or 403A E1 synchronization splitter from the back of the port carrier.

- i. **Error Type 1302:** DS1 configuration error. Attempting to use the 120A1 CSU module with a UDS1 circuit pack that is configured for 32-channel (2.048-Mbps) operation. The CSU module only works with a DS1 board configured for 24-channel (1.544-Mbps) operation in the United States of America.
- m. **Error Type 1303:** DS1 circuit pack suffix incorrect for CSU module/T1 sync splitter or for E1 synchronization splitter.

**DS1 circuit pack suffix incorrect for CSU module/T1 sync splitter:** The **Near-End CSU Type** field on the `add ds1` screen is set to **integrated** but the DS1 circuit pack is not a TN464F or higher suffix UDS1 board.

If the 120A1 CSU module or the 401A T1 sync splitter is to be used, remove the circuit pack and replace it with a TN464F or higher suffix board. Otherwise, use `change ds1` to set the **Near-End CSU Type** field to **other**.

**DS1 circuit pack suffix incorrect for E1 synchronization splitter:** The **E1 Sync-Splitter** field on the `add ds1` screen is set to **y** but the DS1 circuit pack is not a TN464F or higher suffix UDS1 board.

If the 402A or 403A E1 synchronization splitter is to be used, remove the circuit pack and replace it with a TN464F or higher suffix board. Otherwise, use `change ds1` to set the **E1 Sync-Splitter** field to **n**.

- n. **Error Type 1310:** BLB failure. This error occurs when the DS1 Board Loopback (BLB) demand test fails. Repeat the test using `busyout board location, test ds1-loop location ds1/csu-loopback-tests, release board location`. If the BLB test continues to fail, replace the TN464F circuit pack.
- o. **Error Type 1311:** ELB failure. This error occurs when the Equipment Loopback (ELB) test fails for the Integrated CSU (I-CSU) module/T1 sync splitter or for the 402A or 403A E1 synchronization splitter. This test is executed by the I-CSU/E1SS during I-CSU/E1SS power-up/reset (i.e.- UDS1 board physically inserted and 120A1 CSU module, the 401A T1 sync splitter, or the 402A or 403A E1SS is already installed) or when the 120A1 CSU module, the 401A T1 sync splitter, or the 402A or 403A E1SS is plugged on to an already initialized UDS1 DS1 board.

**Note:**

For the **I-CSU/T1 sync splitter** only, the ELB test is also executed as part of `test ds1-loop location ds1/csu-loopback-tests`. Try to clear the alarm using `busyout board location`, `test ds1-loop location ds1/csu-loopback-tests`, and `release board location`. If the ELB test continues to fail, then either the UDS1 board, the CSU module, or the I/O cable between the backplane and the CSU module, or any combination thereof, failed. Try to isolate where the failure is occurring by re-executing the test and by replacing one piece of hardware at a time.

- p. **Error Type 1312:** RLB failure. This error occurs when the Repeater Loopback (RLB) test fails for the Integrated CSU (I-CSU) module/T1 sync splitter or for the 402A or 403A E1 synchronization splitter. This test is executed by the I-CSU/E1SS during I-CSU/E1SS power-up/reset (i.e., DS1 board physically inserted and 120A1 CSU module or the 401A T1 sync splitter, or the 402A or 403A E1SS is already installed) or when the 120A1 CSU module or the 401A T1 sync splitter, or the 402A or 403A E1SS is plugged on to an already initialized DS1 board.

**Note:**

For the **I-CSU/T1 sync splitter** only, the RLB test is also executed as part of the `test ds1-loop location ds1/csu-loopback-tests`. Try to clear the alarm using `busyout board location`, `test ds1-loop location ds1/csu-loopback-tests`, and `release board location`. If the RLB test continues to fail, replace the CSU module.

- q. **Error Type 1313:** CPE Loopback Jack deactivation error. This error occurs when the UDS1 circuit pack could not deactivate a CPE Loopback Jack on power-up/reset or upon software request.

Try to clear the alarm using `busyout board location`, `test ds1-loop location end-loopback/span-test`, and `release board location`. If the attempt to deactivate the CPE Loopback Jack continues to fail, other steps must be taken to deactivate the loopback.

- r. **Error Type 1314:** far CSU Loopback deactivation error. This error occurs when the UDS1 circuit pack could not deactivate a far-end CSU loopback on power-up/reset or upon software request.

Try to clear the alarm using `busyout board location`, `test ds1-loop location end-loopback/span-test`, and `release board location`. If the attempt to deactivate the Far CSU loopback continues to fail, escalate the problem.

- s. **Error Types 1400, 1401:** echo cancellation errors are logged when:

- 1 **Error 1400:** echo canceller function failed. The Echo Canceller Function test, which is executed by firmware, failed.
- 1 **Error 1401:** echo canceller memory failed. The Echo Canceller Memory test, which is executed by firmware, failed.

Echo Cancellation is no longer being supplied by the board. Clear the alarm using the following commands: **busyout board location**, **test board location long**, and **release board location**. If Test #1420 (Echo Canceller test) fails, replace the circuit pack.

- t. **Error Type 1537:** LAN Bus Timeout Error. This error occurs when the circuit pack transmits too many bytes on the LAN bus for a single frame. This condition may be caused by an on-board fault or by faulty data received on one of the circuit pack's external ports. If any of the ports on this circuit pack are alarmed, refer to the repair procedures for those Maintenance Objects.

If the error occurs three times within 10 minutes, the board is isolated from the Packet bus and the board is alarmed. To clear the alarm and restore the board to the Packet bus, use **busyout board location**, **reset board location**, **test board location long**, and **release board location**.

If the problem persists, and there are no PKT-BUS alarms or port alarms, then replace the circuit pack.

- u. **Error Type 1538:** the hyperactive circuit pack is out-of-service and may exhibit one or more of the following symptoms:

- 1 The common circuit pack level tests such as Test #50 and/or Test #52 abort with Error Code 2000.
- 1 The tests run on the ports of this circuit pack return a NO-BOARD result.
- 1 A busyout/release of the circuit pack has no effect on test results.
- 1 A **list configuration** command shows that the circuit pack and ports are properly installed.

The circuit pack is isolated from the system and every trunk or port on this circuit pack is placed into the out-of-service state. The system will try to restore the circuit pack within 20-30 minutes. When no faults are detected for 20-30 minutes, the UDS1 Interface circuit pack is restored to normal operation. Every trunk or port of the UDS1 Interface circuit pack is then returned to the in-service state.

If the board is not restored to normal operation or the error recurs after the board was restored to normal operation, escalate the problem.

- v. **Error Types 3073 to 3160:** for releases of G3V4 and higher, Error Type 3073 shows that this board is receiving slips. The Aux Data contains the last slip count reported.
- w. **Error Type 3330:** LAN critical error. A critical failure has been detected in the Packet bus interface of the circuit pack. This failure may be due to an on-board fault or a Packet bus fault. If the Packet bus is alarmed, see [PKT-INT \(Packet Interface\)](#) for recommended repair procedures.

This error isolates the board from the Packet bus and raises an alarm. If the Packet bus is not alarmed, enter **busyout board location**, **reset board location**, **test board location**, and **release board location**. This should clear the alarm and restore the board to the Packet bus.

If the problem persists, and there are no PKT-BUS alarms, then replace the circuit pack.

- x. **Error Types 3585 to 3601:** for later releases of G3V4 and beyond, Error Type 3585 shows that this board is receiving misframes. The AUX Data contains the last misframe count reported.
- y. **Error Type 3840:** not service-affecting. No action is required. These errors are reported by the circuit pack when it receives a bad control channel message from the switch. The auxiliary data identifies the following error events:

| Aux Data | Event               |
|----------|---------------------|
| 4096     | Bad major heading   |
| 4097     | Bad port number     |
| 4098     | Bad data            |
| 4099     | Bad sub-qualifier   |
| 4100     | State inconsistency |
| 4101     | Bad logical link    |

- z. **Error Type 3841:** the UDS1 Interface circuit pack has detected a transient hardware logic error (for example, program logic inconsistency). This error will disappear when no faults are detected for 100 minutes. The value in Aux Data indicates the type of hardware problem.
- aa. **Error Type 3842:** bad translation RAM location found error. This error is not service-affecting. No action is required. A Bad Translation RAM is detected, but the call continues by using another translation location.
- ab. **Error Type 3843:** LAN Receive Parity Error. This error occurs when the circuit pack detects an error in a received frame from the Packet bus. These errors are most likely caused by a Packet bus problem, but may be due to a circuit pack fault.  
  - See [PKT-INT \(Packet Interface\)](#) to determine whether the problem is isolated to this circuit pack or is caused by Packet bus faults.
- ac. **Error Type 3900:** provides status information about a CPE Loopback Jack test. The value in the Aux Data field indicates the status of the loopback test.

| Aux Data | Test Status                                       |
|----------|---------------------------------------------------|
| 1        | Test is currently running                         |
| 2        | Failed because loopback could not be activated    |
| 3        | Failed because test pattern could not be detected |
| 4        | Test has been terminated                          |

ad. **Error Type 3901:** provides status information about a Far CSU Loopback test. The value in the Aux Data field indicates the status of the loopback test.

| Aux Data | Test Status                                       |
|----------|---------------------------------------------------|
| 1        | Test is currently running                         |
| 2        | Failed because loopback could not be activated    |
| 3        | Failed because test pattern could not be detected |
| 4        | Test has been terminated                          |

ae. **Error Type 3902:** provides status information about a One-Way Span test. The value in the Aux Data field indicates the status of the span test.

| Aux Data | Test Status                                    |
|----------|------------------------------------------------|
| 1        | Test is currently running                      |
| 2        | Failed because test could not be activated     |
| 3        | Test pattern was not received from the far end |
| 4        | Test has been terminated                       |

**Note:**

**G700:** If the One-Way Span test is run between a circuit pack and a DS1 Interface Media Module on a Media Gateway, the test will fail because the DS1 Media Module does not frame-align its test pattern.

af. **Error Type 3999:** indicates that the circuit pack sent a large number of control channel messages to the switch within a short period of time. If Error Type 1538 is also present, then the circuit pack was taken out-of-service due to hyperactivity. If Error Type 1538 is absent, then the circuit pack was not taken out-of-service, but it has generated 50% of the messages necessary to be considered hyperactive. This might be completely normal during heavy traffic periods. However, if this Error Type is logged when the circuit pack is being lightly used, it might indicate a problem with the circuit pack or the equipment attached to it.

## Demand test descriptions and error codes

Investigate tests in the order presented. By clearing errors associated with the first test, errors generated from other tests may also be cleared. Click on the link to see the full description of the test, error codes, and recommended actions.

| Order of Investigation                                   | Short Test Sequence | Long Test Sequence | Reset Board Sequence | test ds1-loop | D/ND <sup>1</sup> |

## VAL-BD (Voice announcements over LAN Circuit Pack)

| MO Name in Log | Alarm Level | Initial Command to Run                | Full Name of MO                               |
|----------------|-------------|---------------------------------------|-----------------------------------------------|
| VAL-BD         | MIN         | <code>test board location long</code> | Voice announcements over the LAN Circuit Pack |
|                | WRN         | <code>test board location</code>      |                                               |

The Voice announcements over the LAN (VAL) TN2501AP provides per-pack announcement storage time of up to one hour, up to 31 playback ports, and allows for announcement file portability over a LAN. The VAL circuit pack also allows for LAN backup and restore of announcement files and the use of user-provided (.WAV) files. The circuit pack also provides the ability to download new versions of the firmware to itself.

---

## Error log entries and recommended actions

Table 274: VAL-BD Error Log entries 1 of 2

| Error Type                | Aux Data  | Associated Test                       | Alarm Level | On/Off Board | Recommended Action                      |
|---------------------------|-----------|---------------------------------------|-------------|--------------|-----------------------------------------|
| 1 (a)                     | 0         | Sanity                                | MIN         | ON           |                                         |
| 18 (b)                    | 0         |                                       | WRN         | OFF          | <code>release board location</code>     |

| 3840 (r)       | 4096–4102 |                                                 |             |              |                                      |
| 3841 3843 (s)  |           |                                                 |             |              |                                      |
| 3842 (t)       |           | Receive FIFO Overflow Error Counter test (#596) |             |              |                                      |
| 3844 (u)       | Any       |                                                 |             |              |                                      |
| 3845 (v)       | Any       |                                                 |             |              |                                      |
| 3846 (w)       | Any       |                                                 |             |              |                                      |
| 3848 (x)       | Any       |                                                 |             |              |                                      |
| 3851 (y)       | Any       |                                                 |             |              |                                      |
| 3852 (z)       | Any       |                                                 |             |              |                                      |
| 3853 (aa)      | Any       |                                                 |             |              |                                      |
| 3854 (ab)      | Any       |                                                 |             |              |                                      |
| 3855 (ac)      | Any       |                                                 |             |              |                                      |
| 3856 (ad)      | Any       |                                                 |             |              |                                      |
|                |           |                                                 |             |              | <b>2 of 2</b>                        |

Notes:

- a. **Error Type 1:** circuit pack stopped functioning or is not physically present.
  1. Verify that the circuit pack is present (`list config board location`).
  2. If circuit pack is present, reset the circuit pack (`reset board location`).
  3. If the error persists, replace the circuit pack.

- b. **Error Type 18:** the VAL circuit pack is busied out. Release the circuit pack.
- c. **Error Type 217:** applies to 10 circuit packs:
  - 1. Remove the circuit pack(s) against which the error is logged.
- d. **Error Type 257:** transient communication problem between switch and circuit pack.
  - 1. Ignore this error, unless the Control Channel Loop test (#52) fails.
  - 2. If Test #52 fails, replace the circuit pack. Repetitive failures of the Control Channel Loop test indicate circuit pack hardware failure.
- e. **Error Type 513:** circuit pack detected and reported hardware failure.
  - 1. Reset the circuit pack (*reset board location*).

Aux Data:

|      |                                |
|------|--------------------------------|
| 4352 | External RAM error             |
| 4353 | Internal RAM error             |
| 4355 | ROM Checksum error             |
| 4356 | Angel Message Corruption error |
| 4357 | Instruction set error          |

- f. **Error Type 769:** logic error. By itself this error can be ignored, but it can result in other Error Types being reported.

g. **Error Type 1281, 1290–1295:** critical hardware or firmware error.

| If the switch detects:  | Then the switch:     |
|-------------------------|----------------------|
| 1 error,                | Resets circuit pack. |
| 3 errors in 15 minutes, | Raises MINOR alarm.  |

Error Type descriptions are as follows:

|      |                                |
|------|--------------------------------|
| 1290 | Global HDLC error              |
| 1291 | Main RAM/ROM error             |
| 1292 | CPU error                      |
| 1293 | Insane on-board processor      |
| 1294 | On-board translation RAM error |
| 1295 | (Aux 3) RSCL link down         |
|      | (Aux 0) RSCL keepalive failure |

1. Attempt to clear the alarm (**reset board location**).
  2. If the alarm persists, replace the circuit pack.
- h. **Error Type 1537, 1796:** a hyperactive VAL circuit pack has exceeded the error threshold and has been removed from service.
1. Attempt to clear the alarm (**reset board location**).
  2. If the error recurs within 15 minutes, replace the circuit pack.
- i. **Error Type 1794:** packet bus transmit buffers have overflowed.
1. Attempt to clear the alarm (**reset board location**).
  2. If the error recurs within 15 minutes, replace the circuit pack.
- j. **Error Type 1798:** unable to write translation RAM.
1. Attempt to clear alarm (**reset board location**).
  2. If the alarm recurs within 15 minutes, replace the circuit pack.
- k. **Error Type 2049:** packet Interface test (#598) failed.
1. Attempt to clear the alarm (**test board location 1 r 3**).
  2. If alarm does not clear, reset the circuit pack (**reset board location**).
  3. If circuit pack resets, execute Packet Interface test (#598) several times.
  4. If Packet Interface test (#598) continues to fail, replace the circuit pack.

**l. Error Type 2305-2306:** error in received frame from packet bus. Most likely a packet bus problem.

Error Type 2305 - Received invalid LAPD frame.

Error Type 2306 - Detected parity error on received frame

Invalid LAPD frame errors occur when the frame:

- 1 contains a bad Cyclic Redundancy Check (CRC)
- 1 is greater than the maximum length
- 1 violates the link-level protocol

1. Run `test board location` and see if the condition clears.
2. If the condition persists, execute the [Invalid LAPD Frame Error Counter Test \(#597\)](#) and determine whether the condition clears.
3. If the condition persists, execute the [Packet Interface Test \(#598\)](#) to verify circuit pack integrity.
4. If the Packet Interface test (#598) fails, see [PKT-BUS \(Packet Bus\)](#) for repair procedures.

**m. Error Type 2561–2668:** system software received an indication that the socket was closed due to an error. Errors are reported as log only. Errors logged here are for the sockets that had *no* processor channels associated with them, for example, sockets to read SNMP data. The counter base is offset by the application type of the application associated with this socket that is down. The Aux Data field of the log entry contains this application's number, for example, a SNMP application would have its application number in the Aux Data field.

**Note:**

2561–2668 is a range of reserved numbers for future applications. 2570 currently represents an SNMP socket failure.

**n. Error Type 2817–2819:** Congestion Query test (#600) failed.

Error Type 2817 - Every buffer exhausted

Error Type 2819 - Utilized buffers exceed threshold

See [Congestion Query Test \(#600\)](#) for repair procedures.

**o. Error Type 3073:** Remote Socket Control Link (RSCL) or [Link Status Test \(#601\)](#) failed. This failure can be due to:

- 1 This circuit pack
- 1 The packet bus
- 1 The packet interface circuit pack.

**If:**

**Then:**

|                                 |                           |
|---------------------------------|---------------------------|
| RSCL disconnects at link level  | Link fails                |
| Link cot be reconnected quickly | Switch raises MINOR alarm |

p. **Error Type 3330:** critical failure in Packet bus interface.

Below, Error Types correspond to descriptions.

| If the switch detects:  | Then it:             |
|-------------------------|----------------------|
| 1 error,                | Resets circuit pack. |
| 2 errors in 15 minutes, | Raises MINOR alarm.  |

1. Attempt to clear the alarm (**reset board location**).
2. If alarm persists, replace circuit pack.

q. **Error Type 3586 and 3999:** switch removed hyperactive circuit pack that reported threshold number of errors. One or more of the following symptoms can be present:

1. Circuit pack port tests return NO BOARD.
1. List configuration command shows circuit pack and ports are installed properly.

| If Error Type 3999:                | And traffic volume is: | Then:                                                                                                                                                                                                  |
|------------------------------------|------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Does not accompany Error Type 3586 | Heavy                  | Circuit pack is in service, but sent at least half hyperactive threshold. With heavy traffic, this is normal.                                                                                          |
| Does not accompany Error Type 3586 | Light                  | Circuit pack is in service, but sent at least half hyperactive threshold. With light traffic, this error indicates a problem with the circuit pack, its links, or the equipment attached to the links. |
| Accompanies Error Type 3586        | Either Light or Heavy  | Switch removed hyperactive circuit pack.                                                                                                                                                               |

1. Enter **busyout board location** and **release board location** to reset the circuit pack.
2. Allow 30 minutes for condition to clear itself.
3. To re-establish circuit pack into service manually, enter **busyout board location**, **reset board location**, and **release board location**.
4. If error recurs within 15 minutes, replace the circuit pack.
5. If the same error occurs on a different circuit pack, follow normal escalation procedures.

- r. **Error Type 3840:** circuit pack received bad control channel message from switch. The Aux Data value displays the cause of the error event:

| Aux Data | Error Cause                |
|----------|----------------------------|
| 4096     | Bad major heading          |
| 4097     | Bad port number            |
| 4098     | Bad data                   |
| 4099     | Bad sub-qualifier          |
| 4100     | State inconsistency        |
| 4101     | Bad logical link           |
| 4102     | Bad application identifier |

- s. **Error Type 3841, 3843:** errors do not affect service.

Error Types correspond to the error descriptions.

|      |                         |
|------|-------------------------|
| 3841 | Internal firmware error |
| 3843 | Bad translation RAM     |

These errors do not affect service, however, they can cause reports of other errors that do affect service.

If Error Type 3843 begins to affect service, it escalates to Error Type 1294 (See Note [g](#)).

- t. **Error Type 3842:** packet interface receive buffers overflowed.

If this error occurs frequently, the overflow can be congesting the circuit pack.

See [Receive FIFO Overflow Error Counter Test \(#596\)](#).

- u. **Error Type 3844:** LAPD frame contains LAPD Protocol Error. By themselves, these errors do not affect service.
- v. **Error Type 3845:** Angel interprocessor error. By themselves, these errors do not affect service.
- w. **Error Type 3846:** main interprocessor error. By themselves, these errors do not affect service.
- x. **Error Type 3848:** main internal channel error. By themselves, these errors do not affect service.
- y. **Error Type 3851:** unable to write LAN translation RAM error. By themselves, these errors do not affect service.
- z. **Error Type 3852:** LAN external RAM error. By themselves, these errors do not affect service.

- aa. **Error Type 3853:** interprocessor LAPD frame error. By themselves, these errors do not affect service.
- ab. **Error Type 3854:** interprocessor LAPD protocol error. By themselves, these errors do not affect service.
- ac. **Error Type 3855:** memory allocation error. By themselves, these errors do not affect service.
- ad. **Error Type 3856:** high CPU occupancy error. By themselves, these errors do not affect service.

---

## Demand test descriptions and error codes

Investigate tests in the order presented. By clearing errors associated with the first test, errors generated from other tests may also be cleared. Click on the link to see the full description of the test, error codes, and recommended actions.

| Order of Investigation                                          | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |

1. D = Destructive; ND = Nondestructive

## VAL-PT (Voice Announcements over LAN Packet/Port)

| MO Name in Log | Alarm Level | Initial Command to Run         | Full Name of MO |
|----------------|-------------|--------------------------------|-----------------|
| VAL-PT         | MAJ<br>MIN  | <i>test port location long</i> | VAL Port        |
|                | WRN         | <i>test port location</i>      |                 |

---

### [S8300 / G700 / G450 / G350 / G430 / G450](#)

The MG- (Voice announcements) maintenance object provides per board announcement storage time of up to 20 minutes (15 playback ports and 1 recording port that can also be used as a playback port), and allows for announcement file portability via LAN connectivity. MG- also allows for LAN backup and restore of announcement files and the use of customer provided waveform (.WAV) files.

The MG- hardware is located on the Media Gateway motherboard. Communication Manager maintenance supports the MG- by using a virtual board concept to allow for board insertion and maintenance testing. The virtual slot location is V9.

---

---

### [S8700 | S8710 | S8720 | S8500](#)

A remote socket control link (RSCL) connects the VAL and the server to pass call-control and other management information. Because one link serves every port on the circuit pack, maintenance of the RSCL is part of the VAL circuit pack maintenance.

---

---

## VAL Congestion Controls

The switch activates congestion controls on VAL when it detects buffers exceeding the threshold. The switch releases the congestion controls when the VAL reports that its buffer level has returned to normal levels.

| If congestion:                    | Then the switch:    |
|-----------------------------------|---------------------|
| Persists for a 14-minute interval | Raises MINOR alarm  |
| Exhausts buffers                  | Raises MINOR alarm  |
| Ceases for 12 minutes             | Retires MINOR alarm |

---

## Error log entries and recommended actions

| Error Type | Aux Data | Associated Test                | Alarm Level | On/Off Board | Recommended Action              |
|------------|----------|--------------------------------|-------------|--------------|---------------------------------|
| 0 (a)      | 0        | Any                            | Any         | Any          | <i>test port location 1</i>     |
| 1 (b)      | 0        | SCOTCH Sync Looparound (#1275) | MIN         | ON           | <i>test port location 1 r 3</i> |
| 257 (c)    | 0        |                                | WRN         | OFF          |                                 |
| 3585 (d)   | 0, 1     | TDM Looparound Test (#1285)    | MAJ         | ON           | <i>test port location 1 r 3</i> |

Notes:

- a. **Error Type 0:** there is no short test sequence for this MO. Every test is available in the long test sequence. Refer to each appropriate test's description, and follow its recommended procedures.
- b. **Error Type 1:** SCOTCH Synchronous Looparound Test (#1275) failed.
  1. Test the port (*test port location long*).
  2. See [SCOTCH Synchronous Looparound Test \(#1275\)](#) for repair procedures.
- c. **Error Type 257:** VAL port detected overrun or underrun condition that can indicate a hardware problem.
  1. Test for hardware problem (*test port location long*).

2. See [SCOTCH Synchronous Looparound Test \(#1275\)](#) repair procedures to verify repair.
  3. Clear the alarm (`test port location long clear`).
- d. **Error Type 3585:** TDM Looparound Test (#1285) failed.
1. Test the port (`test port location long`).
  2. See the [TDM Looparound Test \(#1285\)](#) repair procedure.

---

## Demand test descriptions and error codes

Investigate tests in the order presented. By clearing errors associated with the first test, errors generated from other tests may also be cleared. Click on the link to see the full description of the test, error codes, and recommended actions.

| Order of Investigation                                     | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|------------------------------------------------------------|---------------------|--------------------|-------------------|
| <a href="#">TDM Looparound Test (#1285)</a>                |                     | X                  | D                 |
| <a href="#">SCOTCH Synchronous Looparound Test (#1275)</a> |                     | X                  | D                 |

1. D = Destructive, ND = Nondestructive

## VC-BD (Voice Conditioner Circuit Pack)

| MO Name in Log | Alarm Level      | Initial Command to Run       | Full Name of MO                |
|----------------|------------------|------------------------------|--------------------------------|
| VC-BD          | MAJ<br>MIN       | <i>test board location 1</i> | Voice Conditioner circuit pack |
|                | WRN <sup>1</sup> | <i>test board location</i>   |                                |

1. See [XXX-BD \(Common Port Circuit Pack/Media Module\)](#).

### CAUTION:

If the TN788 Voice Conditioner circuit pack (VC-BD) is not Vintage 2 or later, it must be replaced.

The TN788 Voice Conditioner circuit pack (VC-BD) is a service circuit pack that provides conditioning for the audio signals from multimedia equipment based on the CCITT H.221 standard. The TN788 transcodes, gain adjusts, and bridges the audio bit streams demultiplexed by the TN787 (MMI) circuit pack and transmits encoded, exclusive audio conference sums onto the TDM bus so that the MMI can multiplex the audio, video, and data streams for the H.221 endpoints.

## Error log entries and recommended actions

Table 275: VC-BD Error Log Entries

| Error Type      | Aux Data    | Associated Test                       | Alarm Level | On/Off Board | Recommended Action              |
|-----------------|-------------|---------------------------------------|-------------|--------------|---------------------------------|
| 0 (a)           | 0           | Any                                   | Any         | Any          | <i>test board location</i>      |
| 1 (b)           | Any         | None                                  | MIN         | ON           |                                 |
| 18 (c)          | 0           | <i>busyout board location</i>         | WRN         | OFF          | <i>release board location</i>   |
| 257 (d)         | Any         | Control Channel Looparound Test (#52) | MIN         | ON           | <i>test board location r 20</i> |
| 513 (e)         | 4352-4357   |                                       |             |              |                                 |
| 769 (f)         | 4358        |                                       |             |              |                                 |
| 1025 (g)        | 4363        | NPE Audit Test (#50)                  |             |              |                                 |
| 1281 (h)        | Any         | SAKI Sanity test (#53)                | MAJ         | ON           |                                 |
| 1293 - 1294 (i) | 46088-46096 | SAKI Sanity test (#53)                | MIN         | ON           |                                 |
| 1538 (j)        | 46082       |                                       | MIN         | ON           |                                 |

## Notes:

- a. **Error Type 0:** run the short test sequence first. If every test passes, run the long test sequence. Refer to each appropriate test's description, and follow its recommended procedures.
- b. **Error Type 1:** the circuit pack stopped functioning or it was removed from the system. This alarm is logged approximately 11 minutes after the circuit pack is removed and/or the SAKI Sanity test (#53) fails.

To resolve this error, insert a circuit pack in the same slot as the error indicates, if the circuit pack is not already in the system. Or, if the circuit pack is in the system and the red LED is on, then follow instructions for Red alarms.

 **CAUTION:**

If the TN788 Voice Conditioner circuit pack (VC-BD) is not Vintage 2 or later, it must be replaced.

- c. **Error Type 18:** this circuit pack is busied out by `busyout board location`.
- d. **Error Type 257:** transient communication problems exist between the switch and this circuit pack. Execute `test board location` and see the repair procedures for the [Control Channel Looparound Test \(#52\)](#).
- e. **Error Type 513:** the circuit pack detected an on-board hardware failure. The reported Aux Data values correspond to the following detected errors:

| Error | Description           |
|-------|-----------------------|
| 4352  | External RAM error    |
| 4353  | Internal RAM error    |
| 4355  | ROM Checksum error    |
| 4357  | Instruction set error |

Reset the circuit pack by executing `busyout board location`, `reset board location`, and `release board location`. When it is reset, the circuit pack executes a set of tests to detect the presence of any of the above faults. The detection of one these errors during initialization causes the circuit pack to lock-up and appear insane to the system. See the repair procedures in footnote (a) for Error Type 1.

- f. **Error Type 769:** the circuit pack detects a program logic error. While no action is required, this error may lead to errors of other types being reported against this circuit pack.
- g. **Error Type 1025:** the circuit pack cot update NPE memory and read it back. This Error Type can be ignored, but it may lead to other Error Types being reported against this circuit pack.
- h. **Error Type 1281:** a critical hardware failure has been detected on the circuit pack. Use `busyout board location`, `reset board location`, followed by `release board location`. If Test #53 passes, the on-board circuitry is healthy. Use `test board location long clear` to retire the alarm. If Test #53 fails, replace the circuit pack.

- i. **Error Type 1293 and 1294:** the circuit pack detected a critical hardware failure. Reset the circuit pack with `busyout board location`, `reset board location`, and `release board location`. [Circuit Pack Restart Test \(#594\)](#) passes, then the on-board circuitry is healthy. Retire the alarm by entering `test board location long clear`. If the Circuit Pack Restart test (#594) fails, replace the circuit pack.

The reported Error Types correspond to the following detected errors:

| Error Type | Description                         |
|------------|-------------------------------------|
| 1293       | On-board auxiliary processor insane |
| 1294       | Internal memory access error        |

- j. **Error Type 1538:** the circuit pack is hyperactive — it is flooding the switch with messages sent over the control channel. The circuit pack is taken out of service when a threshold number of these errors is reported to the switch. Clear the alarm by using `busyout board location`, `reset board location`, `test board location long clear`, and `release board location`. If the error recurs within 10 minutes, then replace the circuit pack.

---

## Demand test descriptions and error codes

| Order of Investigation                                | Short Test Sequence | Long Test Sequence | D/ND           |
|-------------------------------------------------------|---------------------|--------------------|----------------|
| <a href="#">Control Channel Looparound Test (#52)</a> | X                   | X                  | Nondestructive |

 **CAUTION:**

If the TN788 Voice Conditioner circuit pack (VC-BD) is not Vintage 2 or later, it must be replaced.

## VC-DSPPT (Voice Conditioner DSP Port)

| MO Name in Log | Alarm Level       | Initial Command to Run    | Full Name of MO            |
|----------------|-------------------|---------------------------|----------------------------|
| VC-DSPPT       | MAJ<br>MIN<br>WRN | <i>test port location</i> | Voice Conditioner DSP Port |

Each Voice Conditioner circuit pack (VC-BD) provides two types of resources:

- 1 Transcoder Resources used for encoding and decoding audio formats
- 1 Summer Resources used for summing audio from different sources

The eight Voice Conditioner DSP ports are the transcoder resources on the VC-BD.

---

## Error log entries and recommended actions

**Table 276: VC-DSPPT Error Log Entries**

| Error Type  | Aux Data | Associated Test                             | Alarm Level | On/Off Board | Recommended Action              |
|-------------|----------|---------------------------------------------|-------------|--------------|---------------------------------|
| 0 (a)       | 0        | Any                                         | Any         | Any          | <i>test port location</i>       |
| 18 (b)      | 0        | <i>busyout port location</i>                | WRN         | OFF          | <i>release port location</i>    |
| 257 (c)     | Any      | VC DSP NPE Crosstalk Test (#1103)           | MIN         | ON           | <i>test port location 1 r 3</i> |
| 513 (d)     | Any      | VC DSP Port Local TDM Loopback test (#1104) | MIN         | ON           | <i>test port location r 3</i>   |
| 778-781 (e) | Any      | VC Port Reset DSP test (#1106)              | MAJ         | ON           |                                 |
| 1025 (f)    |          |                                             | WRN         | ON           |                                 |
| 1281 (g)    | Any      | VC DSP Port DSP Loopback test (#1105)       | MIN         | ON           | <i>test port location r 3</i>   |
| 3840 (h)    |          |                                             |             |              |                                 |

Notes:

- a. **Error Type 0:** run the short test sequence first. If every test passes, run the long test sequence. Refer to each appropriate test's description, and follow its recommended procedures.
- b. **Error Type 18:** this port has been busied out by `busyout port location`.
- c. **Error Type 257:** the NPE Crosstalk test (#6) failed.
- d. **Error Type 513:** the [VC DSP Port Local TDM Loopback Test \(#1104\)](#) failed. Run the long test sequence.
- e. **Error Type 778 - 781:** a critical hardware failure has been detected on the circuit pack. Reset the port by `busyout port location` and `reset port location`. If the VC Reset DSP test (#1106) passes, then the on-board circuitry is healthy. Retire the alarm with `test port location long clear`.
- f. **Error Type 1025:** the VC DSP port reported loss of framing on the Service channel between the VC and MMI circuit packs.
- g. **Error Type 1281:** the [VC DSP Port DSP Looparound Test \(#1105\)](#) failed.
- h. **Error Type 3840:** the DSP corresponding to this port on the VC circuit pack reported a firmware error. No action is required.

---

## Demand test descriptions and error codes

Investigate tests in the order presented. By clearing errors associated with the first test, errors generated from other tests may also be cleared. Click on the link to see the full description of the test, error codes, and recommended actions.

| Order of Investigation                                      | Short Test Sequence | Long Test Sequence | Restart Sequence | D/ND <sup>1</sup> |

1. D = Destructive; ND = Nondestructive

## VC-LEV (Voice Conditioner Resource Level)

| MO Name in log | Alarm Level | Initial Command to Run                             | Full Name of MO                  |
|----------------|-------------|----------------------------------------------------|----------------------------------|
| VC-LEV         | MAJ         | See <a href="#">Resolving VC-LEV Errors/Alarms</a> | Voice Conditioner Resource Level |

The MMCH feature must be enabled on the **System-Parameters Customer-Options** screen before you can change these fields.

The Voice Conditioner (VC) Resource Level MO monitors VC efficiency by tracking the number of VC ports that are in-service, and then comparing that number with the value entered in the VC field on the System-Parameters Maintenance screen. This **VCs** field is located under the Minimum Maintenance Thresholds section. The **VCs** field contains the minimum number of VC ports needed for the Multimedia Call Handling (MMCH) feature, and is an administrable field. The **VCs** field must contain a number between 0 and 126, and is entered by the system administrator. The MMCH feature must be enabled in the License File and corroborated by the System-Parameters Customer-Options screen before the **VCs** field can be changed to a number greater than **0**. For example, administering **8** in that field means 1 circuit pack. The algorithm for determining that a low level of VC resources exists uses the number entered in the **VCs** field, and the number of VCs that are in-service in the system.

Each VC circuit pack contains 16 physical ports: 8 ports are reserved for VC-DSPPT ports, and the remaining 8 ports are designated as VC-SUMPT ports. The 8 DSP ports are made up of 4 encoder and 4 decoder resources that encode and decode audio formats. Thus, *one VC circuit pack is required for every 8 ports of MMCH port capacity*. If the number of in-service VC ports falls below the MMCH port capacity (value entered on the System-Parameters Maintenance screen under the Minimum Maintenance Thresholds section and in the **VCs** field), a VEC-LEV error is logged. If this outage continues for 15 minutes a MAJOR alarm is raised.

---

## Resolving VC-LEV Errors/Alarms

VC ports are a key part of the MMCH feature, any loss in the number of ports available for use degrades the MMCH customer defined service level.

If a VC circuit pack or port is busied out using **busyout board** or **busyout port**, these out-of-service ports are not included in the VC level calculation, thus allowing a technician to busyout a VC circuit pack for maintenance reasons without causing a MAJOR alarm to be raised.

### Note:

When diagnosing a VC-LEV problem, resolve any alarms raised against VC-BD or VC-DSPPT MOs. Clearing VC-BD or VC-DSPPT alarms may clear the VC-LEV alarm.

The VC circuit pack is maintained by the software similarly to the Tone Detector circuit pack. Tone Detector circuit packs may be removed and reinserted in any port-board slot without administration. The same rule applies to VC circuit packs. If a VC circuit pack is removed from service logically (by failing the Archangel sanity scan test) or is removed from service physically (by physically removing the circuit pack from the carrier), no error/alarm is raised against VC-BD or VC-DSPPT MOs. Therefore, if a VC-LEV error/alarm exists, and none has been raised against VC-BD or VC-DSPPT MOs, a VC circuit pack may have been removed from service causing the VC-LEV error/alarm. To resolve a VC-LEV MAJOR alarm, restore the number of VC ports available for service to be equal to or more than the calculated port capacity (value entered in the `VCs` field).

To determine how many VC circuit packs are needed for the MMCH feature:

1. Display the System-Parameters Maintenance screen by executing `display system-parameters maintenance`.
2. Locate the number listed in the Minimum Maintenance Threshold (`VCs`) field. The MMCH feature requires one VC circuit pack for each four ports listed in the Minimum Maintenance Threshold (`VCs`) field.
3. Divide the Minimum Maintenance Threshold value by 8 to determine the number of VC circuit packs needed. For example, a port capacity of 12 listed in the Minimum Maintenance Threshold (`VCs`) field would require 2 VC circuit packs.
4. Use `list configuration` to verify that the number of VC circuit packs listed agrees with the required number of VC circuit packs (determined in step 3). If the number of VC circuit packs listed in the step 3 differs from the calculated number, restore the number of VC circuit packs to the correct value, in order to resolve the VC-LEV alarm.

---

## Error log entries and recommended actions

**Table 277: VC-LEV Error Log Entries**

| Error Type | Aux Data | Associated Test | Alarm Level | On/Off Board | Recommended Action |
|------------|----------|-----------------|-------------|--------------|--------------------|
| 1 (a)      | Any      | None            | MAJ         | OFF          |                    |

Notes:

- a. **Error Type 1:** the number of VC resources in the system that are in service has fallen below the calculated minimum value. If the number of in-service VC ports falls below the MMCH port capacity (value entered in the Minimum Maintenance Threshold `VCs` field on the system parameters maintenance screen), a VEC-LEV error is logged.

If this outage continues for 15 minutes a MAJOR alarm is raised. To resolve this alarm, correct the out-of-service problem:

1. See [VC-DSPPT \(Voice Conditioner DSP Port\)](#) and [VC-BD \(Voice Conditioner Circuit Pack\)](#) to resolve any associated alarms.
2. If a VC-LEV error/alarm exist and none has been raised against VC-BD or VC-DSPPT MOs, a VC circuit pack may have been removed from service causing the VC-LEV error/alarm. To resolve a VC-LEV MAJOR alarm, restore the number of VC ports available for service to be equal to or more than the calculated port capacity. See [Resolving VC-LEV Errors/Alarms](#) for details.

---

## Demand test descriptions and error codes

There are no demand tests for VC-LEV.

## VC-SUMPT (Voice Conditioner Summer Port)

| MO Name in Log | Alarm Level       | Initial Command to Run    | Full Name of MO               |
|----------------|-------------------|---------------------------|-------------------------------|
| VC-SUMPT       | MAJ<br>MIN<br>WRN | <i>test port location</i> | Voice Conditioner Summer Port |

Each Voice Conditioner circuit pack (VC-BD) provides two types of resources:

- 1 Transcoder Resources that are used for encoding and decoding audio formats
- 1 Summer Resources that are used for summing audio formats from different sources.

The Voice Conditioner Summer Ports (VC-SUMPT) are the summer resources on the VC-BD. There are 8 such ports on a VC-BD.

---

## Error log entries and recommended actions

**Table 278: VC-SUMPT Error Log Entries**

| Error Type | Aux Data | Associated Test                            | Alarm Level | On/Off Board | Recommended Action               |
|------------|----------|--------------------------------------------|-------------|--------------|----------------------------------|
| 0 (a)      | 0        | Any                                        | Any         | Any          | <i>test port location</i>        |
| 18 (b)     | 0        | <i>busyout port location</i>               | WRN         | OFF          | <i>release port location</i>     |
| 130 (c)    |          |                                            | WRN         | ON           | <i>test port location</i>        |
| 257 (d)    | Any      | VC DSP NPE Crosstalk Test (#1103)          | MIN         | ON           | <i>test board location 1 r 3</i> |
| 513 (e)    | Any      | VC Summer Port Local Loopback test (#1100) | MIN         | ON           | <i>test board location r 3</i>   |

Notes:

- a. **Error Type 0:** run the short test sequence first. If every test passes, run the long test sequence. Refer to each appropriate test's description, and follow its recommended procedures.
- b. **Error Type 18:** this port has been busied out with *busyout port location*.
- c. **Error Type 130:** the circuit pack has been removed or has been insane for more than 11 minutes. To clear the error, replace or reinsert the circuit pack.
- d. **Error Type 257:** the [VC DSP Port NPE Crosstalk Test \(#1103\)](#) failed.
- e. **Error Type 513:** the [VC Summer Port Local TDM Looparound Test \(#1100\)](#) failed.

---

## Demand test descriptions and error codes

Investigate tests in the order presented. By clearing errors associated with the first test, errors generated from other tests may also be cleared. Click on the link to see the full description of the test, error codes, and recommended actions.

## WAE-PORT (Wideband Access Endpoint Port)

| MO Name in Log | Alarm Level | Initial Command to Run <sup>1</sup>           | Full Name of MO               |
|----------------|-------------|-----------------------------------------------|-------------------------------|
| WAE-PORT       | MIN         | <code>test access-endpoint extension 1</code> | Wideband Access Endpoint Port |
|                | WRN         | <code>test access-endpoint extension</code>   |                               |

1. For additional repair information, see also [DIG-BD \(Digital Line Circuit Pack\)](#) and [MG-DS1 \(DS1 Interface Media Module\)](#).

Wideband Switching supports end-to-end connectivity between customer endpoints at data rates from 128 to 1536 kbps over T1 facilities and to 1984 kbps over E1 facilities. Communication Manager switching capabilities support wideband calls comprised of multiple DS0s that are switched end-to-end as a single entity.

Wideband Switching extends the Administered Connections feature to include non-signaling wideband access endpoints. Endpoint application equipment with direct T1 or E1 interfaces may connect directly to the switch's line-side facilities; application equipment without T1 or E1 interfaces requires a terminal adapter such as a DSU/CSU. The terminal adapter or endpoint application equipment is connected to the TN464C Universal DS1 circuit pack, and to the DS1 Interface Media Module.

### Note:

Not all tests that run on circuit packs are applicable to media modules. These tests will abort with error code 1412. This error can be ignored.

These endpoints are administered as wideband access endpoints and have no signaling interface to switch; they simply transmit and receive data. (Some applications detect and respond to the presence or absence of data). Calls are initiated from these endpoints using the Administered Connections feature.

Multiple access endpoints on one line-side UDS1 circuit pack or DS1 Interface Media Module facility are separate and distinct within the facility. Endpoint application equipment must be administered to send and receive the correct data rate over the correct DS0s. Every Administered Connection originating from a wideband access endpoint uses the entire bandwidth administered for the endpoint. An incoming call with a different data rate than that administered for the endpoint can be routed to the endpoint.

Although Wideband Access Endpoints are used primarily for line-side facilities, these endpoints can also be administered on network DS1 facilities to connect Communication Manager to non-switched network services, such as the Avaya fractional T-1 service. An example of this is the Avaya Static Integrated Network Access, where a trunk group to AT&T 4ESS Switched Services shares an access T-1 facility with a Wideband Access Endpoint. In this case, the Wideband Access Endpoint is connected to the AT&T fractional T-1 service, and it does not terminate on local endpoint equipment, but is connected to a far-end CPE via the dedicated fractional T-1. All Wideband Access Endpoint functionality and operation is identical on both

line-side and network facilities. However, because maintenance capabilities are limited to the Wideband Access Endpoint interface, and because faults can occur end-to-end, troubleshooting procedures based on an end-to-end view of the network is required.

Wideband access endpoint port maintenance provides a strategy to maintain a wideband access endpoint port via a port on the Universal DS1 interface circuit pack or the DS1 Interface Media Module hardware. The maintenance strategy covers logging wideband access endpoint port hardware errors, running tests for port initialization, periodic and scheduled maintenance, demand tests, and alarm escalation and resolution. Two different port service states are specified in the wideband access endpoint port maintenance:

- 1 *out-of-service*: the port is in a deactivated state and cannot be used for calls
- 1 *in-service*: the port is in an activated state and can be used for calls

If the DS1 Interface circuit pack or the DS1 Interface Media Module is out of service, every port on it is taken out of service, and a Warning alarm is raised.

## Error log entries and recommended actions

Table 279: WAE-PT Error Log Entries

| Error Type     | Aux Data | Associated Test                          | Alarm Level | On/Off Board | Recommended Action                          |
|----------------|----------|------------------------------------------|-------------|--------------|---------------------------------------------|
| 0 <sup>1</sup> | 0        | Any                                      | Any         | Any          | <i>test access-endpoint extension</i>       |
| 18 (a)         | 0        | <i>busyout access-endpoint extension</i> | WRN         | OFF          | <i>release access-endpoint extension</i>    |
| 130 (b)        |          |                                          | WRN         | ON           | <i>test access-endpoint extension</i>       |
| 1281 (c)       |          | Conference Circuit Test (#7)             | MIN         | ON           | <i>test access-endpoint extension 1 r 4</i> |
| 1537 (d)       |          | NPE Crosstalk Test (#6)                  | MIN         | ON           | <i>test access-endpoint extension 1 r 3</i> |
| 1793 (e)       |          |                                          |             |              | <i>test board location long</i>             |
| 3840 (f)       | Any      | Port Audit and Update (#36)              |             |              |                                             |

1. Run the short test sequence first. If every test passes, run the long test sequence. Refer to each appropriate test's description, and follow its recommended procedures.

### Notes:

- a. **Error Type 18:** the wideband access endpoint has been busied out by *busyout access-endpoint extension*. No calls can be made to this extension.
- b. **Error Type 130:** the circuit pack or media module has been removed or has been insane for more than 11 minutes. To clear the error, reinsert or replace the circuit pack or media module.

- c. **Error Type 1281:** the Conference Circuit test (#7) failed on this port. See Test #7 for repair procedures.
- d. **Error Type 1537:** the NPE Crosstalk test (#6) failed on this port. See Test #6 for repair procedures.
- e. **Error Type 1793:** the TN464C UDS1 Interface circuit pack or the DS1 Interface Media Module has failed. See [UDS1-BD \(UDS1 Interface Circuit Pack\)](#) or [MG-DS1 \(DS1 Interface Media Module\)](#).
- f. **Error Type 3840:** the Port Audit and Update test (#36) failed due to an internal system error. Enter `status access-endpoint extension` and verify the status of the port. If the wideband access endpoint port is out of service, enter `release access-endpoint extension` to put it back into service. Retry the test command.

1. D = Destructive; ND = Nondestructive

## XXX-BD (Common Port Circuit Pack/Media Module)

| MO Name in Log      | Alarm Level       | Initial Command to Run           | Full Name of MO                                       |
|---------------------|-------------------|----------------------------------|-------------------------------------------------------|
| XXX-BD <sup>1</sup> | MAJ<br>MIN<br>WRN | <code>test board location</code> | Common Port Circuit Pack/<br>Media Module maintenance |

1. Refer to the appropriate circuit pack or media module documentation for the correct MO name displayed in this field.

Common Port Circuit Pack maintenance is a set of common tests used by many circuit packs and media modules. The common portion of these circuit packs/media modules is the generic hardware that interfaces with the TDM bus. The XXX-BD designation is also used on SAT displays when `reset board` is entered with an empty circuit pack or media module slot, or with a circuit pack or media module type that is in conflict with the actual board type administered for that slot.

When any of the Common Port circuit packs or media modules are physically removed from the backplane, no alarm will be logged for approximately 11 minutes. In the case of the following, approximately 21 minutes will elapse before an alarm is logged:

- 1 TN754 Digital Line
- 1 TN758 Pooled Modem
- 1 TN566 EMBEDDED AUDIX
- 1 TN2224 Digital Line Board
- 1 MM712 Digital Line Media Module
- 1 MM717 Digital Line Media Module
- 1 MM720 BRI Media Module
- 1 MM722 BRI Media Module
- 1 MM312 Digital Line Media Module
- 1 IMM-DCP Integrated Digital Line Board
- 1 VMM-2BRI Integrated BRI Media Module
- 1 TIM521 Juniper BRI Media Module

When a circuit pack or media module that has been removed is alarmed, the alarm type is minor and is classified as an on-board alarm. The time delay permits maintenance activity to be performed without triggering an additional alarm.

Alarms are logged against only those common port circuit packs or media modules on which ports have been administered. In a heavily loaded system, the interval between the removal of a Common Port circuit pack or media module and the logging of the alarm may be several minutes longer.

[Table 280: Common MOs](#) contains the list of common circuit pack and media module maintenance objects:

| 23 (c)         | 0        | None                                                      | WRN         | OFF          |                                   |
| 36 (d)         | 4368     | none                                                      |             |              |                                   |
| 125 (e)        |          | None                                                      | MIN         | ON           |                                   |
| 217 (f)        | 0        | None                                                      | WRN         | ON           |                                   |
| 257 (g)        | 65535    | Control channel Looparound Test (#52)                     | MIN         | ON           | <i>test board location r 20</i>   |
| 267 (h)        | 0        | None                                                      | WRN         | ON           |                                   |
| 513 (i)        | Any      | None                                                      | MIN         | ON           | <i>test board location</i>        |
| 769 (j)        | 4358     | None                                                      |             |              |                                   |
| 1025 (k)       | 4363     | NPE Audit Test (#50)                                      |             |              | <i>test board location 1 r 20</i> |
| 1281 (l)       |          | Ringing Application Test (#51)                            | MIN         | ON           | <i>test board location r 2</i>    |
| 1412 (m)       |          |                                                           |             |              |                                   |
| 1538 (n)       | Any      | None                                                      | WRN<br>MIN  | ON           |                                   |
| 1793 (o)       |          | Neon Test (#220)                                          | MIN         | ON           | <i>test board location r 2</i>    |
| 3840 (p)       | Any      | None                                                      |             |              |                                   |
| 3999 (q)       | Any      | None                                                      |             |              |                                   |

1. Run the short test sequence first. If every test passes, run the long test sequence. Refer to each appropriate test's description, and follow its recommended procedures.

Notes:

- a. **Error Type 1:** the circuit pack or media module stopped functioning or has been physically removed from the system. The alarm is logged approximately 11 minutes after removal of the circuit pack or failure of the SAKI Sanity Test (#53).

Check for the physical presence of the circuit pack or media module in the slot indicated by the alarm. If the circuit pack or media module is absent, insert one of the proper type. If the circuit pack or media module is present and its red LED is lit, see the LED alarms without an Alarm Log entry or with Error Type 1 section in *LED Descriptions for Avaya Aura™ Communication Manager Hardware Components (03-602804)*.

- b. **Error Type 18:** the circuit pack or media module has been busied out. Release the circuit pack or media module using **release board location**.

- c. **Error Type 23:** the circuit pack or media module has been logically administered but not physically installed. The alarm should clear when the circuit pack or media module is installed.

If the circuit pack or media module is already installed:

1. Run **test board location long** and look at any test failures or Error Codes generated.
2. If the test does not clear error 23, then execute **reset board location** and run the long test again.
3. If the reset/test does not clear error 23, replace the circuit pack or media module.

- d. **Error Type 36:** this error applies only to the Maintenance/Test circuit pack (TN771B or TN771C). The error indicates that the hardware associated with the Analog Trunk Testing port of the circuit pack failed to initialize. Note that when this error occurs, the Maintenance/Test circuit pack may report an invalid vintage. Although this error is not service-affecting, the Maintenance/Test circuit pack should be replaced.

- e. **Error Type 125:** the circuit pack or media module physically installed in the slot does not match the type that is administered for that slot. Do one of the following:
1. Remove the incorrect circuit pack or media module and replace it with one of the type that is administered for that slot.
  1. Use **change circuit-pack** or **change media-module** to re-administer the slot so that it matches the board that is installed, and follow with **reset board location**.

- f. **Error Type 217:** this error applies to the Maintenance/Test circuit pack (TN771D), Tone Detector (TN748B, TN748C, or TN748D), and Call Classifier (TN748) circuit packs. For the Maintenance/Test circuit pack, the error indicates that there is more than one Maintenance/Test circuit pack in the port network. For the Tone Detector or Call Classifier packs, the error indicates that there are more than 10 circuit packs in the system. Remove the circuit pack against which the error is logged.

- g. **Error Type 257:** transient communication problems between the switch and this circuit pack or media module. Execute `test board location` and refer to the repair procedures for the [Control Channel Looparound Test \(#52\)](#).
- h. **Error Type 267:** transient communication problems with this circuit pack or media module. This error is not service-affecting and no action is required.
- i. **Error Type 513:** This error indicates an on-board hardware failure. The system will continuously test the circuit pack or media module and report the results approximately every 10 minutes. If the hardware problem is resolved, the alarm should clear in approximately 30 minutes. If the alarm does NOT clear in 30 minutes, then the circuit pack or media module should be replaced.
- j. **Error Type 769:** this error can be ignored, but look for other errors on this circuit pack or media module.
- k. **Error Type 1025:** this error is not service-affecting and no action is required.
- l. **Error Type 1281:** no ringing current is detected. Run Test #51, Ringing Application Test, and follow the procedures for [Ringing Application Test \(#51\)](#).
- m. **Error Type 1412:** Test is not applicable to media modules or gateways. This error can be ignored. No action is necessary.
- n. **Error Type 1538:** the hyperactive circuit pack or media module is out-of-service and may exhibit one or more of the following symptoms:
  - 1. The common circuit pack/media module level tests such as Test #51 and/or Test #220 are aborting with Error Code 2000.
  - 2. The tests run on the ports of this circuit pack or media module are returning with a NO-BOARD.
  - 3. A busyout/release of the circuit pack or media module has no effect on test results.
  - 4. A `list configuration` command shows that the circuit pack or media module and ports are properly installed.

If the XXX-BD is not a TN754 Digital Line Circuit Pack (DIG-BD) or Digital Line Media Module, and if this error happens again within 15 minutes, then replace the circuit pack or media module. If the XXX-BD is a TN754 Digital Line Circuit Pack (DIG-BD) or Digital Line Media Module, then check the alarm level. If the alarm level is a WARNING, this indicates that users are probably causing the hyperactivity by adjusting or changing their digital stations. If the circuit pack or media module is very hyperactive, then this alarm will be upgraded to a MINOR alarm within 1 hour. If the alarm level is a MINOR alarm, then replace the circuit pack or media module.
- o. **Error Type 1793:** no neon current is detected. Run `test board location` and follow the procedures for [Neon Test \(#220\)](#).
- p. **Error Type 3840:** this error is not service-affecting and no action is required.
- q. **Error Type 3999:** the circuit pack or media module sent a large number of control channel messages to the switch within a short period of time. If Error Type 1538 is also present, then the circuit pack or media module was taken out-of-service due to hyperactivity. If Error Type

1538 is absent, then the circuit pack or media module was not taken out-of-service, but it has generated 50% of the messages necessary to be considered hyperactive. This may be completely normal during heavy traffic periods. However, if this Error Type is logged when the circuit pack or media module is being lightly used, it may indicate a problem with the circuit pack or media module, or the equipment attached to it.

---

## Demand test descriptions and error codes

Investigate tests in the order presented. By clearing errors associated with the first test, errors generated from other tests may also be cleared. Click on the link to see the full description of the test, error codes, and recommended actions.

## CO Port Diagnostic Test (#3)

For ground start trunks, circuit pack or media module port relays are operated and checked to see if the port can detect and apply ground on the Tip lead. This test also verifies that there is no external ground on the Ring lead. In the absence of other failures, the circuit pack or media module should be replaced only if this test fails with the CO line disconnected.

This test also checks the on-board programmable transmission circuits that allow the circuit pack or media module to support transmission characteristics of several different countries.

This test runs on [CO-TRK \(Analog CO Trunk\)](#) and [DIOD-TRK \(DIOD Trunk\)](#).

## Battery and Power Supply Query Test (#5)

The Battery and Power Supply Query Test queries the PN's Maintenance circuit pack for the status of the battery pack and battery charger, then reports the result. In a DC-powered system, this test should never fail. On AC-powered systems, the test turns the battery charger status LED on and off to determine if the battery charger is connected.

Depending on the cabinet type, this test runs on the following maintenance objects:

- | [AC-POWER](#)
- | [CABINET \(Cabinet Sensors\)](#)
- | [CARR-POW \(Carrier Power Supply\)](#)
- | [DC-POWER \(Single-Carrier Cabinet Environment\)](#)
- | [EMG-XFER \(Emergency Transfer\)](#)
- | [EXT-DEV \(External Device Alarm\)](#)
- | [POWER](#)
- | [RMC-ENV \(Power/Fan Sensors\)](#)
- | [SER-BUS \(Serial Communication Bus\)](#)

| Error Code    | Test Result | Description / Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|---------------|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1005          | ABORT       | <p>The battery charger is not connected. DC-powered cabinets do not have battery backup, so ignore this error if this is a DC-powered cabinet. If the system has a UPS and no battery charger and batteries, ignore this error since the batteries and charger are not required with certain UPSs. Otherwise:</p> <ol style="list-style-type: none"> <li>1. Verify that the battery charger is switched on.</li> <li>2. Unplug one battery.</li> <li>3. Switch off the charger and remove its white power cord.</li> <li>4. Verify that the power cord has at least 106 VAC.</li> <li>5. Verify that the connector on the rear of the charger is properly inserted.</li> <li>6. Re-insert the charger power cord and switch on the charger.</li> <li>7. Plug the battery back in.</li> <li>8. Run the test environment. The batteries may need charging if it was drained if there were power outages. Reconnect the battery charger to recharge. If Test #5 is run before the batteries are completely charged, the test fails with Error Code 2. If Abort 1005 occurs again, escalate the problem.</li> <li>9. Wait 30 hours and rerun the test.</li> </ol> |
| 2000          | ABORT       | <p>Response from the test was not received within the time allowed.</p> <ol style="list-style-type: none"> <li>1. Retry the command at 1-minute intervals up to 5 times.</li> <li>2. For AC-powered systems, if the test continues to ABORT with Error Code 2000, check for system powering problems with the A carrier. Look for and resolve every AC-POWER and CARR-POW alarm in a multicarrier cabinet system. Repeat the test.</li> <li>3. For AC-powered systems, if the test continues to ABORT with a 2000 Error Code, check for and resolve every MAINT (Maintenance circuit pack) error in a PN. Repeat the test.</li> </ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 2028          | ABORT       | <p>An internal system error prevented the Battery Charger status LED from being turned off.</p> <ol style="list-style-type: none"> <li>1. Since this test is not relevant for DC-powered systems, there may be internal system problems. Retry the command at 1-minute intervals up to 5 times.</li> </ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
| <b>2 of 7</b> |             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

| 2                            | FAIL        | <p><b>DC-powered cabinet:</b> The PN's Maintenance circuit pack is incorrectly reporting a problem with power. Replace the suspect circuit pack and run the test again.</p> <p><b>AC-powered cabinet:</b> The system is in nominal power holdover, and the battery is so low that the system will disconnect power very shortly.</p> <ol style="list-style-type: none"> <li>1. If power returns, the port carriers in the PN should power-up again. Every circuit pack should be reinserted, and the system should continue to operate normally. There will probably be a minor alarm against battery and battery charger due to the fact that the batteries are recharging.</li> <li>2. If power does not return, the system will shut down to prevent damage to the batteries. Restore power, and the system will reboot. <i>No manual intervention is required.</i></li> <li>3. Rerun the test. If the test still fails, the PN's MAINT (Maintenance) circuit pack could be reporting this condition incorrectly. Resolve every alarm on this MO, and rerun the test. There are failures that can occur on the PN's Maintenance circuit pack that <i>will not</i> be detected by their respective maintenance, but which will cause many, if not every, environment tests to fail. If many environment tests are failing, the suspect circuit pack, depending on the system configuration, should be replaced and the test rerun.</li> </ol> |
| <b>3 of 7</b>                |             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

**Table 284: Battery and Power Supply Query Test (#5) 4 of 7**

| Error Code | Test Result | Description / Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| 4          | FAIL        | <p><b>DC-powered cabinet:</b> The PN's Maintenance circuit pack is incorrectly reporting a problem with power. Replace the suspect circuit pack and run the test again.</p> <p><b>AC-powered cabinet:</b> The battery is currently being charged.</p> <ol style="list-style-type: none"> <li>1. After 30 hours, the battery should be fully charged, and this error should clear.</li> <li>2. If after 30 hours the battery is still in the high charge rate, an alarm will be raised. Enter <b>display errors</b> to display the Error Log, and select the category "environs" to show only environment-related errors. Look for POWER errors of type 257. The first occurrence of this error indicates the time when the battery started charging. Use this time as the starting point to determine whether the battery has been charging for 30 hours. If so, replace the battery and battery charger.</li> </ol> <p> <b>CAUTION:</b><br/>Read the section, <a href="#">Replacing the Battery and Battery Charger (J58890CE)</a> before proceeding.</p> <ol style="list-style-type: none"> <li>3. Rerun the test. If the test still fails, the PN's MAINT (Maintenance) circuit pack could be reporting this condition incorrectly. There are failures that can occur on the PN's Maintenance circuit pack that will not be detected by their respective maintenance, but which will cause many, if not every, environment test to fail. If many environment tests are failing, the suspect circuit pack, depending on the system configuration, should be replaced and the test rerun. Resolve every alarm on these MOs, and rerun the test.</li> </ol> |
| 6          | FAIL        | <p><b>DC-powered cabinet:</b> The PN's Maintenance circuit pack is incorrectly reporting a problem with power. Replace the suspect circuit pack and run the test again.</p> <p><b>AC-powered cabinet:</b> This indicates that Error Codes 2 and 4 occurred. Refer to these descriptions. Also, refer to this test's description for Error Code 14.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

| 8          | FAIL        | <p><b>DC-powered cabinet:</b> The PN's Maintenance circuit pack is incorrectly reporting a problem with power. Replace the suspect circuit pack and run the test again.</p> <p><b>AC-powered cabinet:</b> For a global AC MCC (J58890CH), use the procedures outlined in step <a href="#">3</a>.</p> <p>There is a reserve power fault. A problem exists with the battery charger or, less likely, the batteries. Also, this fault could be generated if the charger is switched off or a battery is unplugged.</p> <ol style="list-style-type: none"> <li>1. Replace the battery charger and the battery. The fault should disappear. <ul style="list-style-type: none"> <li>Always turn off the battery charger before replacing the batteries.</li> </ul> </li> <li>2. Rerun the test. If the test still fails, the PN's MAINT (Maintenance) circuit pack could be reporting this condition incorrectly. Resolve every alarm on this MO, and rerun the test. Some failures on the PN's Maintenance circuit pack are not detected by maintenance, but they cause environment tests to fail. If many environment tests fail, replace the suspect circuit pack and rerun the test.</li> <li>3. Procedures for a Global MCC (J58890CH): <ol style="list-style-type: none"> <li>a. See if any red LEDs are "on" on any of the rectifier modules or the BIU (Battery Interface Unit) located in the Power Distribution Unit (J58890CH).</li> <li>b. If the BTW (Battery Temp Warning) LED on the BIU is "on," check the batteries for an over temp condition. If temp is normal, replace the BIU. If the test still fails, replace the battery in a small battery system. For a large battery system, escalate the problem.</li> </ol> <p><b>Note:</b> The equipment must be installed in a well-ventilated area. Maximum equipment performance is obtained at an ambient room temperature between 40 and 120 degrees Fahrenheit (4 and 49 degrees Celsius) for short term operation (not more than 72 consecutive hours or 15 days in a year) and up to 110 degrees Fahrenheit (43 degrees Celsius) for continuous operation.</p> <ol style="list-style-type: none"> <li>c. If the BNA (Battery Not Available) LED is "on," check the battery connections including connector J20.</li> </ol> </li> </ol> |

## NPE Crosstalk Test (#6)

For the majority of maintenance objects, this test is known as the NPE Crosstalk Test (#6). One or more Network Processing Elements (NPEs) reside on each circuit pack with a TDM Bus interface. The NPE controls port connectivity and gain, and provides conference functions on a per-port basis. This test verifies that the port's NPE channel talks on the selected time slot and never crosses over to time slots reserved for other connections. If the NPE is not working correctly, one-way and noisy connections may be observed. This test takes about 20 to 30 seconds to complete.

For **MMI-BD**, this test is known as the TSI Crosstalk Test (#6). The Time Slot Interchanger (TSI) chip controls connectivity to the TDM bus. The TSI Crosstalk test verifies that this TSI talks on the selected TDM bus time slot and never crosses over to time slots reserved for other connections. If the TSI is not working correctly, one-way and noisy connections may occur. If the test passes, the TSI can communicate over the TDM bus. This test takes approximately 20 to 30 seconds to complete.

For **VC-SUMPT**, this test is known as the VC-SUMPT Port NPE Crosstalk Test (#6). It is a slightly modified version of the NPE Crosstalk Test

This test runs on the following maintenance objects:

- 1 [ADX16A-P \(AUDIX Analog Line/Control Link\)](#)

---

## Conference Circuit Test (#7)

The Conference Circuit Test verifies that the Network Processing Element (NPE) channel for the port being tested can correctly perform the conferencing function. The NPE is instructed to listen to several different tones and conference the tones together. The resulting signal is then measured by a Tone Detector port. If the level of the tone is within a certain range, the test passes.

This test runs on the following maintenance objects:

- 1 [ADX16A-P \(AUDIX Analog Line/Control Link\)](#)
- 1 [AN-LN-PT \(Analog Line Port\)](#)
- 1 [ANL-16-L \(16-Port Analog Line\)](#)

## Maintenance Demand Tests

- | [CO-DS1 \(DS1 CO Trunk\)](#)
- | [DAT-LINE \(Data Line Port\)](#)
- | [DID-DS1 \(Direct Inward Dial Trunk\)](#)
- | [DIOD-DS1 \(DS1 DIOD Trunk\)](#)
- | [ISDN-TRK \(DS1 ISDN Trunk\)](#)
- | [OPS-LINE \(DS1 Off-Premises Station Line\)](#)
- | [\\_PE \(Processor Ethernet\) Alarms](#)
- | [S-SYN-PT \(Speech Synthesis Port\)](#)
- | [TIE-DS1 \(DS1 Tie Trunk\)](#)
- | [WAE-PORT \(Wideband Access Endpoint Port\)](#)

## GPP NPE Crosstalk Test (#9)

The General-purpose Port (GPP) Network Processing Element (NPE) Crosstalk Test verifies that the port's NPE channel talks on the selected time slot and that it never crosses over to time slots reserved for other connections. One or more NPEs reside on each circuit pack with a TDM-bus interface. The NPE controls port connectivity and gain, and provides conferencing functions on a per-port basis. An NPE that is not working correctly may cause one-way and noisy connections. This test takes about 20 to 30 seconds to run.

Crosstalk testing is performed on both the primary (for voice) and the secondary (for data) information channel associated with each port. If this test fails on either channel, the port is taken out of service.

This test is run on the following maintenance objects:

- 1 [ADX8D-PT \(AUDIX Digital Port\)](#)
- 1 [ADX16D-P \(16-Port AUDIX Digital Port\)](#)
- 1 [DIG-LINE \(Digital Line\)](#)
- 1 [E-DIG-ST \(Emulated Digital Line\)](#)
- 1 [M/T-ANL \(Maintenance/Test Analog Port\)](#)
- 1 [M/T-DIG \(Maintenance/Test Digital Port\)](#)
- 1 [PDMODULE \(Processor Data Module\)](#)
- 1 [TDMODULE \(Trunk Data Module\)](#)

---

## Digital Line Electronic Power Feed Test (#11)

**For TN413, and TN754 vintage 13 or earlier**, this is the Electronic Power Feed (EPF) Restoral Test. In this test, the processor requests that the EPF be turned on for a given port, and an attempt is made to turn on the power supply to the station. If no current is drawn, the station is probably not connected. If an overcurrent condition is sensed, there may be a short in the loop. A message is returned reporting that either the EPF was successfully turned on, or that an overcurrent condition was sensed. This test is repeated again 5 seconds later.

**For TN754 vintage 14 or later, TN754B and TN2136**, this is a Positive Temperature Coefficient (PTC) Restoral Test. In this test, the processor requests that the PTC be turned on for a given port, and an attempt is made to turn on the power supply to the station. If an overcurrent condition is sensed, there is probably a short on the power line that causing the PTC to open and disconnect the voice terminal. Since the PTC does not have self-restoral capability, the voice terminal must be manually unplugged for 30 seconds and then plugged back in to restore the PTC. A message is returned reporting that either the PTC was successfully turned on successfully with no problem or an overcurrent condition was sensed. This test is repeated again 5 seconds later.

**For TN2181 and TN2224** boards, this is a Protected Power Feed restoral test, since the boards carry Protected Power Feed (PPF) relays, one for each port. The test procedure and its response is same as that of EPF. One of differences between EFP and PPF is that, if the port goes into a overcurrent state, PPF does not report this change of state because it is a transient state which will not last more than 50ms. If the overcurrent persists, the power will be shut off automatically.

**For MM717 Media Modules**, this is an EPF Restore Test. The Media Module provides power to the terminals. The test procedure and its response is same as that of EPF. If the overcurrent persists, the power will be shut off automatically.

This test runs on the following maintenance objects:

- 1 [DIG-LINE \(Digital Line\)](#)
- 1 [RC-BD \(Radio Controller Board\)](#)

|            |             | <b>2 of 2</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

## Local Loop Test (#13)

This test is executed on the following maintenance objects:

- 1 [ADX8D-PT \(AUDIX Digital Port\)](#)
- 1 [ADX16D-P \(16-Port AUDIX Digital Port\)](#)
- 1 [DIG-LINE \(Digital Line\)](#)
- 1 [E-DIG-ST \(Emulated Digital Line\)](#)
- 1 [M/T-ANL \(Maintenance/Test Analog Port\)](#).
- 1 [M/T-DIG \(Maintenance/Test Digital Port\)](#)
- 1 [PDMODULE \(Processor Data Module\)](#)
- 1 [TDMODULE \(Trunk Data Module\)](#).

For **ADX8D-PT**, **ADX16D-P**, **DIG-LINE**, and **E-DIG-ST**, this test is known as the Voice and Control Channel Local Loop Test (#13). This test consists of four tests that check the information and control channels between the server and the port circuit. If any of the tests fail or abort, the test sequence stops and the result is reported.

For **M/T-ANL**, this test is known as the Analog Port Digital Looparound Test (#13). The test performs a loop test on the data channel and TDM bus, then runs a conference test.

For **M/T-DIG**, this test is known as the Digital Port Looparound Test (#13). The test performs a loop test on the data channel and TDM bus, then runs a conference test.

For **PDMODULE** and **TDMODULE**, this test is known as the Information and Control Channel Looparound Test (#13). This is a set of four tests that check the operation of the information and control channels used between Communication Manager and the Digital Line port circuit.

User impact from problems with this port many range from no noticeable effect to not being able to use this port. Users may not notice a disruption in service. In extreme cases, the conferencing feature may not work at all.

**Table 289: Local Loop Test (#13) 1 of 9**

| Error Code | Test Result | Description / Recommendation                                                                                                                                                                        |

## Digital Station Lamp Update (#16)

This test lights all lamps on the terminal as specified. The lamp updates run only if the station is in-service. The lamp updates are blocked from taking place if the station is not in the in-service state. This test does not affect the status of the Message Waiting lamp.

This test runs on the following maintenance objects:

- | [DIG-IP-S \(Digital IP Station\)](#)
- | [DIG-LINE \(Digital Line\)](#)
- | [E-DIG-ST \(Emulated Digital Line\)](#)
- | [RC-BD \(Radio Controller Board\)](#)

## Digital Station Audits Test (#17)

This test is a series of audits. This test is run on PDMODULE, TDMODULE, digital stations, softphone applications, and IP phones. This test is run on a station only if the station is in-service. The following audits are performed:

- 1 Switch hook Inquiry: This is an update of the server's software records based on the on-hook/off-hook status of the data module or voice terminal.
- 1 Station ID Request: A request is made to the data module or station for its status. The data module or station returns its configuration and health information. This information is checked and a pass/fail result is provided.
- 1 EPF inquiry: The test requests the status of the Electronic Power Feed. EPF is not used for data modules.
- 1 Bad Scan Inquiry: An uplink message is sent containing a count generated by certain events relating to the link conditions. This can be an indication of communication problems between the server and the digital port board or media module.
- 1 Ringer Update: This updates the ringer state according to the server's records.
- 1 DTMP Administration Update: This sends a message to the digital station to refresh the default value that causes the station to send touch-tones only in the primary information channel. This value is initially set when the station is put in-service and each time the station's state changes from another state to in-service. This test is not used with data modules.

This test runs on the following maintenance objects:

- 1 [DIG-IP-S \(Digital IP Station\)](#)
- 1 [DIG-LINE \(Digital Line\)](#)
- 1 [PDMODULE \(Processor Data Module\)](#)
- 1 [TDMODULE \(Trunk Data Module\)](#)
- 1 [RC-BD \(Radio Controller Board\)](#)

## Looparound and Conference Test (#33)

The Looparound and Conference Test checks the reflective and non-reflective looparound and conference capabilities of a trunk port circuit. It transmits 404-Hz, 1004-Hz, and 2804-Hz tones. Each tone is transmitted separately to and from the port, then verified

Disabling this test also disables the Port Diagnostic Test (#35).

This test runs on the following maintenance objects:

- 1 [AUX-TRK \(Auxiliary Trunk\)](#)
- 1 [CO-TRK \(Analog CO Trunk\)](#)
- 1 [DID-TRK \(Direct Inward Dial Trunk\)](#)
- 1 [DIOD-TRK \(DIOD Trunk\)](#)
- 1 [TIE-TRK \(Analog Tie Trunk\)](#)

| 7<br>129<br>131<br>133 | FAIL        | <p>No transmission was detected to or from the port. The problem may be off-board.</p> <p>Error Code 7 - The conference capabilities of the port failed.<br/>                     Error Code 129 - The reflective 404-Hz tone test failed.<br/>                     Error Code 131 - The reflective 1004-Hz tone test failed.<br/>                     Error Code 133 - The reflective 2804-Hz tone test failed.</p> <ol style="list-style-type: none"> <li>1. If the Looparound and Conference test fails for every port on a circuit pack, a -5 Volt power problem is indicated. See <a href="#">CARR-POW (Carrier Power Supply)</a> or <a href="#">RMC-ENV (Power/Fan Sensors)</a>.</li> <li>2. If a red LED is lit on the power unit circuit pack, replace the circuit pack.</li> <li>3. If the test fails on more than one port, check for TONE-BD and TONE-PT errors. If there are errors, see <a href="#">TONE-BD (Tone-Clock Circuit Pack)</a> and/or <a href="#">TONE-PT (Tone Generator)</a>. When the tone errors have been resolved, rerun the test.</li> <li>4. <b>S8700-series Fiber-PNC:</b> if the test fails again, see <a href="#">Fault Isolation Using Duplicated PNC</a></li> <li>5. To check if the problem is on-board, disconnect the port from the auxiliary equipment or CO and retry the test. If disconnecting from the CO, coordinate the disconnect with the CO or do it after hours. Otherwise, the CO may put the connection out of service. If the retry fails, replace the circuit pack.</li> <li>6. If the test passed after disconnecting the port from the auxiliary equipment or CO, the problem is off-board.</li> </ol> <p><b>AUX-TRK:</b> Check the wiring and connections to the auxiliary equipment and retry the test after reconnecting the port to the auxiliary equipment. If the test fails, check the auxiliary equipment. See the preceding procedure for a failure with Error Code 7.</p> <p><b>All other Maintenance Objects:</b> If the test passes and no troubles have been reported, disable the test by changing the <b>Maintenance Tests</b> field to <b>y</b> on the <b>change trunk-group x</b> screen, where <b>x</b> is the trunk group number. If the test passes and troubles have been reported, refer the problem to the CO.</p> |

## Port Diagnostic Test (#35)

This test is also known as the Battery Feed Test.

The battery feed chip provides power to the telephone equipment, signaling, rotary dial pulsing, transmission, and balance. This test checks the signaling and switch hook capabilities of the battery feed chip by terminating the port, applying battery, and trying to detect a current.

This test is run on the following maintenance objects:

- 1 [ADX16A-P \(AUDIX Analog Line/Control Link\)](#)
- 1 [ALARM-PT \(Alarm Port\)](#)
- 1 [AN-LN-PT \(Analog Line Port\)](#)
- 1 [ANL-16-L \(16-Port Analog Line\)](#)
- 1 [ANL-LINE \(8-Port Analog Line\)](#)
- 1 [DID-TRK \(Direct Inward Dial Trunk\)](#)
- 1 [MET-LINE \(MET Line\)](#)
- 1 [RANL-STA \(Remote Analog Line \(Station\) Port\)](#)

## Port Audit And Update Test (#36)

The Port Audit and Update Test sends port level translation data from the switch processor to the circuit pack to verify that the port’s translation and current state are correct.

When the ringer is in the off state, this test also turns off the station’s ringer to prevent constant ringing caused by defective hardware.

For an analog line port which is administered as an external alarm, this test is limited to updating the software with the switchhook state.

This test runs on the following maintenance objects:

- 1 [ADX16A-P \(AUDIX Analog Line/Control Link\)](#)
- 1 [ALARM-PT \(Alarm Port\)](#)

- | [AN-LN-PT \(Analog Line Port\)](#)
- | [ANL-16-L \(16-Port Analog Line\)](#)
- | [ANL-LINE \(8-Port Analog Line\)](#)
- | [AUX-TRK \(Auxiliary Trunk\)](#)
- | [CO-DS1 \(DS1 CO Trunk\)](#)
- | [CO-TRK \(Analog CO Trunk\)](#)
- | [DAT-LINE \(Data Line Port\)](#)
- | [DID-DS1 \(Direct Inward Dial Trunk\)](#)
- | [DID-TRK \(Direct Inward Dial Trunk\)](#)
- | [DIOD-DS1 \(DS1 DIOD Trunk\)](#)
- | [DIOD-TRK \(DIOD Trunk\)](#)
- | [ISDN-TRK \(DS1 ISDN Trunk\)](#)
- | [OPS-LINE \(DS1 Off-Premises Station Line\)](#)
- | [\\_PE \(Processor Ethernet\) Alarms](#)
- | [RANL-STA \(Remote Analog Line \(Station\) Port\)](#)
- | [TIE-DS1 \(DS1 Tie Trunk\)](#)
- | [TIE-TRK \(Analog Tie Trunk\)](#)

This test is also known as the Station Status and Translation Audits and Updates Test (#36)

## Tone Generator Transmission Test (#40)

This test verifies that the tone generation hardware on the IPSI or Tone-Clock circuit pack is capable of generating a subset of system tones and a set of test tones. This test does not verify all system tones the tone generator produces during normal system operation.

The test is performed in two parts. For the first part, the Tone Generator is told to generate the touch-tone digits. The digits are received and checked by a Tone Detector's touch-tone detector. If any of the digits fail, the test is repeated using a touch-tone detector in another Tone Detector circuit pack.

For the second part, the Tone Generator is told to generate call-progress tones that are detected and identified by a tone detector. These tones are:

- | 440 Hz
- | 2225 Hz
- | Digital Count

The tone generator is then told to generate a sequence of test tones. The output levels are measured by a tone detector. These tones are:

- | 404 Hz at 0 dB
- | 1004 Hz at -16 dB
- | 1004 Hz at 0 dB
- | 2804 Hz at 0 dB

A Tone Detector's general-purpose tone detector listens for tones and measures their quality. If any of the measured values are not within certain limits, the test is repeated using a general-purpose tone detector in a different Tone Detector circuit pack. If the values are still not in the acceptable range of the limits, the test will fail.

For every failure case of Test #40, do the following:

1. Check that all Tone Detector circuit packs have the same companding mode as that administered for the system. Correct the situation if there is a mismatch.
2. Run the long test sequence: `test tone-clock location long`
3. If the problem persists, replace the IPSI or Tone-Clock circuit pack by following the steps outlined in [Replacing the IPSI or Tone-Clock Circuit Pack](#).

This test runs on the following maintenance objects:

- | [TDM-CLK \(TDM Bus Clock\)](#)
- | [TONE-BD \(Tone-Clock Circuit Pack\)](#)
- | [TONE-PT \(Tone Generator\)](#)

## Notes:

Except in EPNs containing more than one IPSI or Tone-Clock circuit pack, replacing an IPSI or Tone-Clock circuit pack is a service disrupting procedure. The test should be run several times with more than one failure before the replacement policy specified in the following notes is executed. Use the procedure described in [Replacing the IPSI or Tone-Clock Circuit Pack](#).

## Maintenance Demand Tests

- a. This error may affect users if the failure is on the active tone generator. When this type failure is detected, the system will attempt to move the tone generation function to the alternate IPSI or Tone-Clock circuit pack, if one is present in the affected port network. When the tone generation facility fails in this way, especially in a port network without duplicated IPSI or Tone-Clock circuit packs, the faulty IPSI or Tone-Clock circuit pack should be replaced promptly.
- b. This error is almost transparent to the user. When this type failure is detected, the system will attempt to move the tone generation function to the alternate IPSI or Tone-Clock circuit pack, if one is present in the affected port network. Users may or may not hear any noisy tones. This type of failure affects maintenance on other objects. Maintenance may not be able to run on other objects which use the tone generation facility (that is, Tone Detector circuit maintenance). In this case, the IPSI or Tone-Clock circuit pack can be replaced as suitable to the customer.
- c. Error code 115 may also be caused by TDM bus corruption. There may be a physical problem with bent backplane pins, TDM/LAN bus cabling, or TDM/LAN bus terminators. Such physical problems should especially be suspected if board replacement or other physical activity has occurred just before this error is observed.

Enter **display errors** to look for errors on other circuit packs in the carriers of the same port network as the indicated Tone-Clock circuit. If any are found, they should be resolved if possible, and the IPSI or Tone-Clock circuit pack retested. If this does not clear the problem, the IPSI or Tone-Clock circuit pack should be replaced and the new one tested. If the problem persists, follow the instructions for [TDM-BUS \(TDM Bus\)](#).

---

## Tone Generator Update/Audit Test (#41)

This test refreshes the active tone generation facility with all the time slot tone information. This test also triggers inline error messages the IPSI or Tone-Clock circuit pack generates when it detects problems by itself.

A check is made between the type of Tone-Clock being tested and the type of Tone-Clock needed based on system administration. The administration on the system-parameters country-options screen may imply that a TN780 is required.

This test runs on the following maintenance objects:

- 1 [TDM-CLK \(TDM Bus Clock\)](#)
- 1 [TONE-BD \(Tone-Clock Circuit Pack\)](#)
- 1 [TONE-PT \(Tone Generator\)](#)

## Tone Detection Verification Test (#42)

The test checks the operation of the circuit pack in touch-tone receiver, call classifier, and MFC modes. It verifies the circuit pack's ability to detect DTMF, ring back, busy reorder, and modem answer tones, and to generate and detect forward and backward MFC tones.

This test runs on the following maintenance objects:

- 1 [CLSFY-PT \(Call Classifier Port\)](#)
- 1 [DTMR-PT \(Dual-Tone Multifrequency Receiver Port\)](#)
- 1 [ETR-PT \(Enhanced Tone Receiver Port\)](#)
- 1 [GPTD-PT \(General-Purpose Tone Detector Port\)](#)

1 [TONE-BD \(Tone-Clock Circuit Pack\)](#)

**Table 297: Tone Detection Verification Test (#42) 1 of 3**

## Tone Detector Audit/Update Test (#43)

The Tone Detector Audit/Update Test performs a sanity audit on the following port types:

- 1 [CLSFY-PT \(Call Classifier Port\)](#)
- 1 [DTMR-PT \(Dual-Tone Multifrequency Receiver Port\)](#)
- 1 [ETR-PT \(Enhanced Tone Receiver Port\)](#)
- 1 [GPTD-PT \(General-Purpose Tone Detector Port\)](#)
- 1 [TONE-BD \(Tone-Clock Circuit Pack\)](#)

Table 298: Tone Detector Audit/Update Test (#43)

| Error Code | Test Result | Description / Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

|            | FAIL        | Hardware audit failed.<br>1. Enter <code>list configuration carrier</code> to get the board type and location. If the board type is TN2182, TN2312, or TN8412, do steps 2 – 6. Otherwise, do steps 7 - 9.<br>2. Check if the board is duplicated using the commands <code>list cabinet</code> and <code>status port-network</code> on the affected PN.<br>3. If the board is duplicated, switch to the standby side using <code>set tone</code> or <code>set ipserver-interface</code> .<br>4. Test the alarmed board using <code>test tone location long</code> . This command resets the board. This will probably will not affect calls in progress, but could cause a call origination to abort or cause a user to not get dial tone when going off-hook.<br>5. If every test passes and the alarm does not resolve, retest using <code>test tone location long clear</code> .<br>6. If the test passes, terminate the repair process. If it fails, replace the circuit pack at the customer's convenience. Follow the procedures in <a href="#">TONE-BD (Tone-Clock Circuit Pack)</a> .<br>7. Attempt to reset the circuit pack. The reset is required to reload RAM associated with the DSPs. This will take all tone detector ports out of service for a few seconds. Other than the unlikely potential of running out of tone detector resources in the switch, there is no other effect when the board is reset.<br>8. Test the board using <code>test board location long</code> .<br>9. If the test passes, terminate the repair process. If the test fails, replace the board. Follow the procedures in <a href="#">TONE-BD (Tone-Clock Circuit Pack)</a> . |
|            | PASS        | The port passed the sanity audit.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

## Clock Health Inquiry Test (#46)

The Clock Health Inquiry Test reads special data stored in memory to determine if the IPSI or Tone-Clock circuit pack had a loss of any of three clock types:

- 1 SYSCLK
- 1 SYSFM
- 1 SYSDCLK

If this data indicates this IPSI or Tone-Clock circuit pack had a loss of any of these clocks, the test fails. TDM-CLK Error 1 indicates a suspect clock is at the edge of its specified frequency. If the circuit pack did not have a loss of clock, the test passes.

This is not really a test, in the sense that it simply reports status held by the system, and does not generate new information or raise alarms. If this test fails with no Error Code, there is at least one Major alarm against an IPSI or Tone-Clock circuit pack. If this test fails with an Error Code of 1, there is at least one Minor off-board alarm against a TDM-CLK.

This test runs on the following maintenance objects:

- 1 [TDM-CLK \(TDM Bus Clock\)](#)
- 1 [TONE-BD \(Tone-Clock Circuit Pack\)](#)
- 1 [TONE-PT \(Tone Generator\)](#)

---

## Looparound and Conference Test (#47)

Each analog port consists of:

- 1 An NPE (Network Processing Element) for port connectivity, gain, and conferencing functionality
- 1 A codec that converts TDM Bus digital signals to analog
- 1 A battery feed chip that provides power to the telephone set for signaling, dial pulsing, transmission, and balance.

## Maintenance Demand Tests

This test checks the on-board transmission capabilities of the NPE, the codec, and the battery feed chip of the analog port. A Tone Detector and a Tone Generator talk and listen on the same pair of time slots as the analog port. The analog port is then instructed to go into looparound mode (see [Figure 96: Looparound and Conference Test](#)). The test passes if the signal measured by the Tone Detector is within acceptable limits.

The Conference Circuit test verifies that the NPE channel for the port being tested can correctly perform the conferencing function. Test #47 also tests the operation of the port conference circuits in the NPE for three and four parties. In addition, a test is run to measure noise. The NPE is instructed to listen to several different tones and conference the tones together. The resulting signal is then measured by a Tone Detector port. If the level of the tone is within a certain range, the test passes.

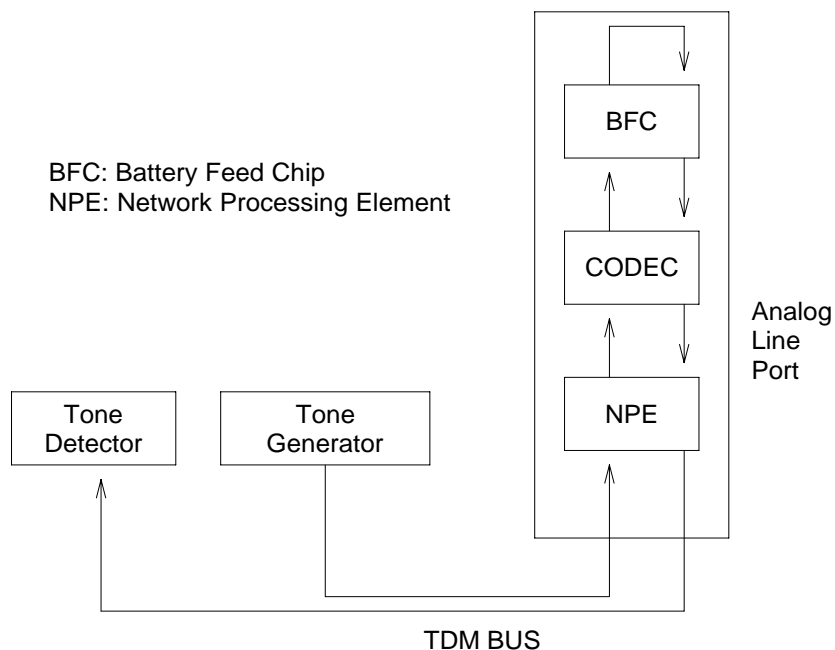

The noise test is performed by filtering out the tone and measuring inherent port noise.

Problems with the port can cause noisy or unreliable connections, or users may report hearing an echo.

### Note:

This looparound test is sensitive to the length of the loop, the equipment in the loop, or the equipment terminating the loop, such as off-premises stations. If this test is causing a false alarm, use **change station** for this station and change the **Tests** field to **n** to disable the test.

**Figure 96: Looparound and Conference Test**

This test is run for [ANL-LINE \(8-Port Analog Line\)](#).

|---------------------|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 7<br>13<br>14<br>15 | FAIL        | <p>A test failed.</p> <ul style="list-style-type: none"> <li>1 Error Code 7 - The conference test or the noise test failed.</li> <li>1 Error Code 13 - The reflective looparound test with gain set to low and 600-ohm balance failed.</li> <li>1 Error Code 14 - The reflective looparound test with gain set to high, using RC, balance failed.</li> <li>1 Error Code 15 - The nonreflective looparound test failed.</li> </ul> <ol style="list-style-type: none"> <li>1. Disconnect the terminal equipment from the circuit pack at the cross-connect and run the test again.</li> <li>2. If the test fails again, replace the circuit pack and reconnect the terminal equipment. If the test passes the second time, this means the test results were affected by the terminal equipment connected to the port. In this case, ignore the results of this test if every other test passes or aborts and the station is operating properly. Failure of test 47 does not cause an alarm. If there are failures of other tests, investigate those errors. Investigate user-reported troubles with this port by using other port tests, by examining station wiring, and by examining the station to ensure that it is correctly translated as off-premises or on-premises.</li> </ol> <p>If the Looparound and Conference circuit test fails for every port on a circuit pack, a -5 Volt power problem is indicated. If a TN736 or TN752 power unit circuit pack is present, either the 631DB AC power unit or the 676B DC power unit may be defective. (The 631DB power unit is used in a medium cabinet powered by an AC source. The 645B power unit is used in a medium cabinet powered by a DC power source.) The system may contain a TN736 or TN752 power unit circuit pack or a 631DB AC power unit, but not both types of power units. To investigate problems with the power unit, see <a href="#">RMC-ENV (Power/Fan Sensors)</a> or <a href="#">CARR-POW (Carrier Power Supply)</a>. If a red LED is lit on TN736 or TN752 power unit circuit pack, replace the pack. If the test fails on more than 1 port, check for errors on the TONE-BD or the TONE-PT. If errors exist, take appropriate actions. When the tone errors are cleared, rerun the test.</p> |

## ONS Ringer Application Test (#48)

The Ringing Application Test applies momentary ringing voltage to the terminal equipment to determine if the terminal equipment is connected to the port. The test may cause some terminal equipment to ring briefly during daily maintenance. If this ringing disturbs the customer or the terminal equipment, disable it using the **Tests** field on the **Station** screen. With some software releases, Tests #6, #7, #35, and #161 are also disabled.

This test is also known as the Station Present Test (#48).

This test runs on the following maintenance objects:

- 1 [ADX16A-P \(AUDIX Analog Line/Control Link\)](#)
- 1 [ANL-16-L \(16-Port Analog Line\)](#)
- 1 [AN-LN-PT \(Analog Line Port\)](#)
- 1 [ANL-LINE \(8-Port Analog Line\)](#)

1 [RANL-STA \(Remote Analog Line \(Station\) Port\)](#)

**Table 301: ONS Ringer Application Test (#48) 1 of 2**

## NPE Audit Test (#50)

The NPE Audit Test sends a message to the circuit pack to update the network connectivity translation for all the Network Processing Elements (NPEs) on the circuit pack.

This test runs on the following maintenance objects:

- 1 [-BD \(Announcement circuit pack\)](#)
- 1 [ATM-TRK \(Circuit Emulation Service Circuit Pack\)](#)
- 1 [BRI-BD \(ISDN-BRI Line Circuit Pack\)](#)
- 1 [CO-BD \(Central Office Trunk Circuit Pack\)](#)
- 1 [DS1-BD \(DS1 Interface Circuit Pack\)](#)
- 1 [MAPD-BD \(MAPD Interface Circuit Pack\)](#)
- 1 [MG-ANA \(Analog Media Module\)](#)
- 1 [MG-BRI \(BRI Trunk Media Module\)](#)
- 1 [MG-DCP \(Digital Line Media Module\)](#)
- 1 [MG-DS1 \(DS1 Interface Media Module\)](#)
- 1 [MG-IAMM \(Integrated Analog Media Module\)](#)
- 1 [M/T-BD \(Maintenance/Test Circuit Pack\)](#)
- 1 [RC-BD \(Radio Controller Board\)](#)
- 1 [TBRI-BD \(ISDN Trunk-Side BRI Circuit Pack\)](#)
- 1 [UDS1-BD \(UDS1 Interface Circuit Pack\)](#)
- 1 [XXX-BD \(Common Port Circuit Pack/Media Module\)](#)

 **CAUTION:**

Though normally nondestructive, this test could unintentionally tear down an active call if the internal software tables are corrupt.

## Ringling Application Test (#51)

The Ringling Application Test checks the ringling application circuitry common to every port on an Analog Line circuit pack. This test runs on the following maintenance objects:

- 1 [MG-ANA \(Analog Media Module\)](#)
- 1 [MG-IAMM \(Integrated Analog Media Module\)](#)

1 [XXX-BD \(Common Port Circuit Pack/Media Module\)](#).

**Table 303: Ringing Application Test (#51) 1 of 2**

| Error Code    | Test Result | Description / Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

| 1008          | ABORT       | Could not allocate a ringing circuit for one of the following reasons: all the ringing circuits are in use; the ringing generator is defective; ringing generator is not wired correctly.<br>1. If the test continues to abort, look for RING-GEN errors in the Error Log.<br>a. If there are RING-GEN errors, see <a href="#">RING-GEN (Analog Ring Generator)</a> and try to resolve any problem(s). Then retry the test at 1-minute intervals up to 5 times.<br>b. If there are no RING-GEN errors, and the test continues to abort, enter <b>test board location</b> on other TN742, TN769, or TN746 Analog circuit packs. If an ABORT with Error Code 1008 occurs for this test on other circuit packs as well, then the ringing generator may be defective or may not be wired properly. See <a href="#">RING-GEN (Analog Ring Generator)</a> maintenance documentation for details. If an ABORT with Error Code 1008 does NOT occur on the other ports, then all four ring generators are in use. No further action is necessary.<br>2. Retry the command at 1-minute intervals up to 5 times. |
| 1412          | ABORT       | This test does not run on media modules or media gateways. Ignore.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

## Control Channel Looparound Test (#52)

The Control Channel Looparound test queries a circuit pack or media module for its board code and vintage to check the operation of the control channel and board communication. The test passes if the correct board code and vintage are returned. The test aborts if there is no response. The test fails otherwise. This test runs on the following maintenance objects:

## SAKI Sanity Test (#53)

**This test is destructive.**

The SAKI Sanity Test resets the circuit pack or media module. It is executed as part of the `reset board location` command.

## Maintenance Demand Tests

For **IPMEDPRO**: Use the **change ip-interface** screen to disable the Media Processor's IP interface before performing this procedure.

For the Tone-Clock circuit packs, DS1 Interface circuit packs, and DS1 Interface Media Modules, this test is executed as part of the long test sequence.

This test is run on the following maintenance objects:

- | [DS1-BD \(DS1 Interface Circuit Pack\)](#)
- | [MAPD-BD \(MAPD Interface Circuit Pack\)](#)
- | [MEDPRO \(Media Processor MAPD Circuit Pack\)](#)
- | [MG-ANA \(Analog Media Module\)](#)
- | [MG-DS1 \(DS1 Interface Media Module\)](#)
- | [MMI-BD \(Multimedia Interface Circuit Pack\)](#)
- | [RC-BD \(Radio Controller Board\)](#)
- | [TDM-CLK \(TDM Bus Clock\)](#)
- | [TONE-BD \(Tone-Clock Circuit Pack\)](#)
- | [TONE-PT \(Tone Generator\)](#)
- | [UDS1-BD \(UDS1 Interface Circuit Pack\)](#)
- | [XXX-BD \(Common Port Circuit Pack/Media Module\)](#)

## Analog Electronic Power Feed Test (#56)

The test requests that the EPF be turned on for a given port. The hardware then attempts to turn on that port's station power unit. If no current is drawn, the station is probably not connected. If an overcurrent condition is sensed (too much current is drawn), a short may exist in the loop or the voice terminal may be defective. The test results indicate either the EPF was turned on successfully with no problems or an overcurrent condition exists. This test is repeated after a 5 second delay. If either test is not successful, the test aborts.

Although this test will never actually return a fail result except for the internal system error, an Error Type 257 entry will be made in the error log after the test has completed if the overcurrent case is detected by the hardware.

This test is run on [HYB-LINE \(Hybrid Line\)](#) and [MET-LINE \(MET Line\)](#).

|            | PASS        | The Analog Electronic Power Feed test passed. The message to turn on the power to the station was successfully sent to the port.<br><br>1. Although this test will never actually return a FAIL result except for an <i>internal system error</i> , it will log an error if the overcurrent case is detected by the hardware. Check the Error Log for any entries with Error Type 257 when the test has completed.<br><br>2. If Error Type 257 does not appear in the Error Log within 10 seconds after completion of this test, it is safe to assume that the test sensed no problems with the power to the station. To verify that the station is powered up correctly, run a self-test on the station, if available, and check that every feature button is operating.<br><br>3. The appearance of Error Type 257 in the Error Log indicates a station power problem. Check for a wiring short, a damaged jack, a defective voice terminal, or an incorrect type of terminal. |

|            |             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

## Hybrid Circuit and Conference Circuit Test (#57)

This test checks two different port circuit functions. It performs an analog reflective looparound measurement on the port's hybrid circuitry. The Conference Circuit test performs a conference test on the port's Network Processing Element (NPE).

For the test results to be valid, a voice terminal must be connected to the port being tested. The test instructs the on-board microprocessor to put the port in analog reflective looparound mode. The Tone-Clock circuit pack supplies a 1004-Hz tone to the port's listen time slot and a GPTD (General-Purpose Tone Detector) measures the level of the reflected signal appearing on port's talk time slot.

The Conference test is performed only if the Hybrid Circuit test passes. The Conference Circuit test verifies that the NPE can correctly conference several test tones together. The test is executed in two parts. The first half of the test verifies operation of the NPE's first three conference channels, and the second half verifies the NPE's remaining four conference channels. The test puts the NPE in looparound mode and instructs it to talk on a specified time slot while listening to a 1004-Hz tone using the Conference Channels. A GPTD then measures the signal and noise levels of the conferenced output and reports whether or not these fall within a specified acceptable range.

This test is run on [HYB-LINE \(Hybrid Line\)](#) and [MET-LINE \(MET Line\)](#).

| 7          | FAIL        | The Conference Test failed. The user may be able to use conference circuit without difficulty in some cases. In other extreme cases, conference calling will be totally restricted.<br>The failure may be due to off-board circumstances, the most common of which is an off-hook occurring during the test. Also, check the error logs against the GPTD-BD, the TONE-BD, and the TONE-PT.<br>1. This error can be caused by a disconnected terminal. Ensure that the terminal is connected and the wiring is OK.<br>2. Enter <b>display port</b> and <b>status station</b> to determine whether the station is idle. If so, enter <b>test port</b> for this port.<br>3. If test continues to fail, enter <b>busyout port</b> , <b>reset port</b> , <b>release port</b> , then retest the port.<br>4. It is possible that the port may still be functional from a user's point of view. |
| 57         | FAIL        | The Hybrid Circuit test failed. This can result in noisy or bad connections.<br>1. Run circuit pack tests to check the Tone Generator circuit pack and the Tone Detector circuit pack, using <b>test board location</b><br>2. Resolve any problems that are detected on the Tone Generator circuit pack or Tone Detector circuit pack.<br>3. If the Tone Generator and Tone Detector circuit packs are functioning properly, and the test still fails, replace the MET Line or Hybrid Line circuit pack.<br>If the Hybrid Circuit and Conference Circuit test fails for every port on a circuit pack, a -5 Volt power problem is indicated. To investigate problems with a power unit, see <a href="#">RMC-ENV (Power/Fan Sensors)</a> , or <a href="#">CARR-POW (Carrier Power Supply)</a> .                                                                                           |
|            |             | <b>3 of 4</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

## Hybrid Line Local Digital Looparound Test (#58)

This test checks the control channel between the server and the port's digital circuitry. The server sends data to the on-board microprocessor and compares the data echoed back. This test is run on [HYB-LINE \(Hybrid Line\)](#).

Table 308: Hybrid Line Local Digital Looparound Test (#58) 1 of 2

## Hybrid Line Remote Digital Looparound Test (#59)

This test checks the digital control pair from the port circuit to the terminal. The on-board microprocessor sends a message to the terminal and checks for a proper return message. This test is repeated three times, with two out of the three attempts passing being sufficient for this test to pass. This test will run if the station is in service or out of service.

This test is run on [HYB-LINE \(Hybrid Line\)](#).

## Analog Line Station Lamp Update Test (#60)

For this test, the lamps on the terminal are turned on based on the status record contained in the processor. The lamp updates run only if the station is in-service.

This test is run on [HYB-LINE \(Hybrid Line\)](#) and [MET-LINE \(MET Line\)](#).

Table 310: Analog Line Station Lamp Update Test (#60) 1 of 2

| Error Code    | Test Result | Description / Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

## Analog Line Audits Test (#61)

This test is a series of three audits. These audits will abort if attempted on an out-of-service station. The tests are as follows:

- 1 Switchhook Audit: This updates the server’s records according to the circuit packs’ records.
- 1 Bad Scan Inquiry: An uplink message is sent containing a count generated due to certain events relating to the data link’s conditions. This indicates data-transmission problems between the circuit pack and the voice terminal.
- 1 EPF Inquiry: An uplink status message of the Electronic Power Feed is sent.

This test is run on [HYB-LINE \(Hybrid Line\)](#) and [MET-LINE \(MET Line\)](#).

## Tie Trunk Seizure Test (#73)

This test performs a seizure test on an analog tie trunk. The tie trunk must be outgoing, and be wink-start, delay-dial, continuous-seize-ack, discontinuous-seize-ack trunks, or TGU/E/I. This test activates the M lead and checks for a response from the far end within 10 seconds.

The test seizes a trunk and outpulses a pause. The port reports the result of the seizure. This test can be disabled using the **Test** field on the Trunk Group Administration screen.

This test aborts on ports administered as access endpoints.

This test runs on [TIE-TRK \(Analog Tie Trunk\)](#).

Table 313: Tie Trunk Seizure Test (#73) 1 of 3

| Error Code    | Test Result | Description / Recommendation                                                                                                     |

---

## Tie Trunk EPF Test (#74)

The first part of this test checks for proper activation and deactivation of the port's E lead. The second part checks the M lead electronic power feed current flow.

## Maintenance Demand Tests

This test runs on [TIE-TRK \(Analog Tie Trunk\)](#).

**Table 314: Tie Trunk EPF Test (#74) 1 of 2**

| Error Code | Test Result | Description / Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

## RMC Power/Fan Query Test (#77)

This test queries the TN2312AP IPSI circuit pack for the status of the cabinet sensors in the G600 media gateway (RMC). Only one alarm lead is supported by this cabinet type to indicate a power, temperature, or a fan problem. A failure of this test can also indicate a power problem, not necessarily just a temperature/fan problem.

This test runs on [RMC-ENV \(Power/Fan Sensors\)](#).

| 1             | FAIL<br>(cont'd) | <p>5. If the fans are running at high speed, check the following items. Any one of these could be restricting or redirecting the cabinet's air flow.</p> <ul style="list-style-type: none"> <li>1 Check the filter. If the filter is dirty or clogged, it should be cleaned or replaced. The filter can either be washed with soap and water or vacuumed.</li> <li>1 Verify that nothing other than circuit packs are in the carrier slots that could be restricting air flow.</li> <li>1 Verify that no circuit-pack blanks or carrier faceplates are missing. Install and/or replace them as necessary.</li> <li>1 Verify the cabinet's doors are properly closed. The doors must be closed to enable the fans to properly cool the cabinet. Wait 5 minutes to allow the fans to cool the cabinet. Rerun the test. If the test still fails, proceed to Step 6.</li> </ul> <p>6. At this point, there should be nothing impeding the air flow and the fans should be running at high speed. Check the temperatures for the 5- to 60<sup>0</sup>-C criteria.</p> <ul style="list-style-type: none"> <li>1 If the 5 to 60<sup>0</sup>C criteria exists, a temperature problem exists, and the fans (at high speed) should cool down the switch. Wait 5 minutes, and rerun the test. If the test still fails, the ambient room temperature is probably too high, and the room should be cooled.</li> </ul> <p>If not, the fans are defective. Replace the fan assembly and rerun the test. Failures can occur on the Processor circuit pack which are not detected but can cause many, if not every, environment test to fail. If several environment tests are failing, the suspected circuit pack, depending on the system configuration, should be replaced and the test rerun.</p> |
|               | FAIL             | <p>There is a problem with the environment of the power system. The power unit for the cabinet may be defective.</p> <ul style="list-style-type: none"> <li>1. Verify and, if necessary, replace the power unit.</li> <li>2. Rerun the test. If the test still fails, escalate the problem.</li> </ul>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|               | PASS             | <p>The cabinet does not have a power or fan problem. If a problem is reported, troubleshoot by using the previous procedures for the FAIL cases.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

## AC Power Query Test (#78)

The AC Power Query Test queries either the server's watchdog via an Ethernet or USB interface or an MCC PN's Maintenance circuit pack for the status of the cabinet's AC power.

The AC Power Query Test (#78) is not valid for DC-powered cabinets and should either abort or pass.

This test runs on the following maintenance objects:

- | [AC-POWER](#)
- | [CABINET \(Cabinet Sensors\)](#)
- | [CARR-POW \(Carrier Power Supply\)](#)
- | [EMG-XFER \(Emergency Transfer\)](#)
- | [POWER](#)

For a nominal holdover system, if there is no AC power at the wall outlet, have a qualified electrician restore power to the outlet. Power should range from 170 to 264 VAC.</li> <li>2. If there is AC power at the wall outlet, there could be a problem with the RM0850 rectifiers, BU3200A BIU (battery interface unit), or battery. Resolve every alarm logged against <a href="#">POWER</a>, and rerun the test.</li> <li>3. If the test still fails, the BIU may be defective. Check the BIU. If the BOD alarm LED is on, replace the BIU. If the BOD LED is off and the BOK LED is on, a PN's Maintenance circuit pack may be incorrectly reporting the problem. Resolve every alarm against these MOs, and rerun the test.</li> </ol> |
|            |             | <b>2 of 3</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

Table 316: AC Power Query Test (#78) 3 of 3

| Error Code                       | Test Result | Description / Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

## Single-Carrier Cabinet Power Query Test (#79)

This test queries an PN's Maintenance circuit pack about the power status in a single-carrier cabinet PN. This test can only detect power problems in the carriers of the PN where the Carrier Port Power Supply physically resides.

This test runs on the [DC-POWER \(Single-Carrier Cabinet Environment\)](#) maintenance object.

## Tone Generator Crosstalk Test (#90)

The Tone Generator Crosstalk Test verifies the ability of the Tone Generator to talk on a specific time slot. The other idle time slots are checked to make sure the Tone Generator put the tone on only the specified time slot.

This test runs on the following maintenance objects:

- 1 [TDM-CLK \(TDM Bus Clock\)](#)
- 1 [TONE-BD \(Tone-Clock Circuit Pack\)](#)

1 [TONE-PT \(Tone Generator\)](#)

**Table 318: Tone Generator Crosstalk Test (#90) 1 of 2**

| Error Code | Test Result | Description / Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

## Modem Pool NPE Crosstalk Test (#96)

This test is destructive.

The Modem Pool Crosstalk Test verifies that the Network Processing Element (NPE) is connected only to the desired time slot and is not crosstalking on other time slots. This test operates exactly like the NPE Crosstalk Test #6 for other types of port circuits, but it is performed twice in order to test both NPEs in the Modem Pool Port.

This test runs on [MODEM-PT \(Modem Pool Port\)](#).

## Modem Pool Conference Test (#97)

**This test is destructive.**

The Modem Pool Conference Test checks most of the switching and gain control functions provided by the NPE circuit in the analog section of the conversion resource. This test conferences a 1004-Hz tone through the NPE, looping it back so that it can be verified with a Tone Detector circuit

This test runs on [MODEM-PT \(Modem Pool Port\)](#).

**Table 320: Modem Pool Conference Test (#97) 1 of 4**

| Error Code    | Test Result | Description / Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

## Modem Pool Conversion Resource Looparound Test (#98)

The Modem Pool Conversion Resource Looparound test is set up as follows:

**Figure 97: Modem Pool Conversion Resource Looparound**

## Maintenance Demand Tests

Test data patterns are transmitted from a Maintenance/Test board's digital port over network time slot A through the digital port on the conversion resource, looped around through the analog port via time slot C back to the Maintenance/Test board's digital port circuit via time slot B where the patterns are checked for accuracy. Finally, the test forces a disconnect by breaking the connection between the Maintenance/Test board's digital port and the Modem Pool port (time slot A) and verifying that the Maintenance/Test board's digital port and Modem Pool port go on-hook within the proper time. This test attempts to allocate a Maintenance/Test board's digital port, Modem Pool port, and other internal resources. If any of these allocation attempts fail, the test cannot be completed, and a specific abort error is reported.

This test runs on [MODEM-PT \(Modem Pool Port\)](#).

---

## Modem Pool Audit Test (#99)

This audit updates the Modem Pool conversion resource status contained in the TN758 Pooled Modem circuit pack's microprocessor. It does not test the Pooled Modem circuit pack, so there are no FAIL codes. The audit can only be performed on idle conversion resources. If the conversion resource is in use, the audit aborts.

This test runs on [MODEM-PT \(Modem Pool Port\)](#).

**Table 322: Modem Pool Audit Test (#99)**

| Error Code | Test Result | Description / Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
|------------|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Any        | ABORT       | <p>The system was not able to allocate all necessary resources to run this test. The conversion resource was in use when the audit was performed. No repair action is necessary unless the conversion resource was known to be idle during the test (amber in-use LED was off) or was busied out before the test was run. In that case, a TN758 failure condition may exist and the following steps should be used:</p> <ol style="list-style-type: none"> <li>1. Busyout both of the TN758 Pooled Modem conversion resources on the circuit pack containing the failing conversion resource.</li> <li>2. If the test continues to abort, replace the Pooled Modem circuit pack and retest.</li> </ol> |
|            | PASS        | The audit passed.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |

## Sanity Handshake Test (#106)

This test checks the ability of a PN's Maintenance circuit pack's to respond to queries. A message is sent to the PN's Maintenance circuit pack. The test passes if a valid cabinet type is returned. This test runs on [MAINT \(PN Maintenance Circuit Pack\)](#).

**Table 323: Sanity Handshake Test (#106) 1 of 2**

| Error Code | Test Result | Description / Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

## Auxiliary Trunk Diagnostic Test (#114)

The system sends a message to the on-board microprocessor to operate a relay in the port circuit. If ground is detected, the test passes. This test runs on the [AUX-TRK \(Auxiliary Trunk\)](#) maintenance object.

**Table 324: Auxiliary Trunk Diagnostic Test (#114)**

| Error Code | Test Result | Description / Recommendation                                                                                                                                                                                                                                                                                                                                                                                                |

## Customer-Provided Alarming Device Test (#115)

The Customer-Provided Alarming Device (CPAD) Test closes the relay that activates the CPAD for one minute. If more than one minute is necessary to verify CPAD activation, use the **repeat** option for the **test customer-alarm location** command to close the relay for up to 99 minutes. For example, entering **test customer-alarm location r 5** closes the relay for five minutes.

When the repeat option is used, the results for Test #115 come back immediately and, for each test that passed, the CPAD is kept on for one minute. The CPAD does not turn off after the PASS result and then turn back on. Instead, the CPAD is kept on continuously for the entire time. If the CPAD is being activated and deactivated in a flickering fashion, there is a problem with either the CPAD or a PN's Maintenance circuit pack.

This test runs on [CAB-CALM \(Customer alarm\)](#) and [MAINT \(PN Maintenance Circuit Pack\)](#).

**Table 325: Customer-Provided Alarming Device Test (#115)**

| Error Code | Test Result | Description / Recommendations                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

## Carrier Power Supply Recycle Override Test (#116)

The Carrier Power Supply Recycle Override Test test is **destructive**.

This test removes power from the specified carrier and causes all circuit packs in the recycled carrier to be removed and inserted. These actions cause all calls originating from or terminating to circuit packs in this carrier to be dropped. The pair of OLSs in the specified carrier is recycled. Both OLSs in the carrier are turned off for 2 seconds and then back on again. After the OLSs have been turned back on, the test queries a PN's Maintenance circuit pack for the status of the pair of OLSs in the specified carrier. If both OLSs are on and functioning, then the test passes. If both OLSs are not on and functioning, the test fails, and BOTH OLSs are turned off.

This test is run on [CARR-POW \(Carrier Power Supply\)](#) with the `recyle carrier override` command.

**Table 326: OLS Recycle Test (#116) 1 of 2**

| Error Code | Test Result | Description / Recommendation                                                                                                  |

## Ring Generator Initialization Test (#117)

The Ring Generator Initialization Test sends a request to the active TN768, TN780, TN2182 Tone-Clock or TN2312AP/BP IPSI circuit pack's Tone-Clock circuit to monitor the voltage. The Tone-Clock responds with an error if the ringing voltage falls too low.

This test is run on the following maintenance objects:

- 1 [AC-POWER](#)
- 1 [CABINET \(Cabinet Sensors\)](#)
- 1 [CARR-POW \(Carrier Power Supply\)](#)
- 1 [DC-POWER \(Single-Carrier Cabinet Environment\)](#)
- 1 [EMG-XFER \(Emergency Transfer\)](#)
- 1 [EXT-DEV \(External Device Alarm\)](#)

- | [POWER](#)
- | [POW-SUP \(Power Supply\)](#)
- | [RING-GEN \(Analog Ring Generator\)](#)
- | [RMC-ENV \(Power/Fan Sensors\)](#)
- | [SER-BUS \(Serial Communication Bus\)](#)

## Ring Generator Query Test (#118)

The Ring Generator Query test requests the active Tone-Clock circuit pack to check the ringing voltage. The Tone-Clock circuit pack replies with PASS if the ringing voltage is adequate to ring the analog phones. If not, the active Tone-Clock circuit pack replies with a FAIL.

This test runs on the following maintenance objects:

- | [AC-POWER](#)
- | [CABINET \(Cabinet Sensors\)](#)

## Maintenance Demand Tests

- | [CARR-POW \(Carrier Power Supply\)](#)
- | [DC-POWER \(Single-Carrier Cabinet Environment\)](#)
- | [EMG-XFER \(Emergency Transfer\)](#)
- | [EXT-DEV \(External Device Alarm\)](#)
- | [POWER](#)
- | [POW-SUP \(Power Supply\)](#)
- | [RING-GEN \(Analog Ring Generator\)](#)
- | [RMC-ENV \(Power/Fan Sensors\)](#)
- | [SER-BUS \(Serial Communication Bus\)](#)

|               | FAIL        | <p>Procedure for a <b>single-carrier</b> cabinet system:</p> <p>There is no ringing voltage in the carrier where the active Tone-Clock circuit pack resides. Other carriers may or may not have ringing voltage.</p> <ol style="list-style-type: none"> <li>1. If this is a duplicated system, determine the active Tone-Clock circuit pack. Enter <code>set tone-clock location</code> to make the standby Tone-Clock circuit active, and rerun the test. <ol style="list-style-type: none"> <li>a. If the test passes, then the trouble is with the “new” stand by Tone-Clock circuit pack. See <a href="#">TONE-BD (Tone-Clock Circuit Pack)</a> for details on replacing the standby Tone-Clock circuit pack. After the circuit pack is replaced, use <code>set tone-clock location</code> to make this Tone-Clock circuit active, and rerun the test.</li> <li>b. If the test fails, proceed with Step 2.</li> </ol> </li> <li>2. Unseat every analog circuit pack in the cabinet that contains the active Tone-Clock circuit pack, and rerun the test.</li> <li>3. If the test passes, then the ring generator is healthy and one of the analog circuit packs is defective. Replace the analog circuit packs one at a time, and rerun the test to determine which circuit pack is causing the problem. Replace the defective analog circuit pack. Rerun the test. If the test still fails, go to Step 4.</li> <li>4. Replace the WP-91153 power unit for the affected carrier, and rerun the test. If the test still fails, go to Step 5.</li> <li>5. The active Tone-Clock may be faulty and incorrectly reporting the level of the ringing voltage. Replace the active Tone-Clock, and rerun the test. See <a href="#">TONE-BD (Tone-Clock Circuit Pack)</a> for details on replacing the active Tone-Clock circuit pack. Rerun the test.</li> </ol> |
|               | PASS        | The analog ringing voltage level is acceptable. For a single-carrier cabinet stack, ringing voltage is acceptable in the cabinet containing the active Tone-Clock circuit pack.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

## External Device Alarm Query Test (#120)

The External Device Alarm Query Test determines if the Major or Minor external alarm leads have been connected to ground, indicating an alarm condition in the adjunct equipment. The test has no affect on the external device itself. The `test environment` command will report an error against Test #120 if there is a short on one or both of the pairs of leads connecting the external device. This test runs on the following maintenance objects:

- | [AC-POWER](#)
- | [CABINET \(Cabinet Sensors\)](#)
- | [CARR-POW \(Carrier Power Supply\)](#)
- | [DC-POWER \(Single-Carrier Cabinet Environment\)](#)
- | [EMG-XFER \(Emergency Transfer\)](#)
- | [EXT-DEV \(External Device Alarm\)](#)
- | [POWER](#)

 **CAUTION:**

Alarms can be generated on adjunct equipment, sent to the Avaya system, and recorded and reported as "external alarms". The adjunct equipment must provide an isolated contact closure across the alarm leads provided by the Avaya system. The contact must be rated at a minimum of 60 V DC, with a current carrying capacity of 5 mA minimum.

There are failures that can occur on the TN775 and TN2312BP IPSI/TN8412AP SIPI circuit pack that <i>are not</i> detected but cause environment tests to fail. If more than two environment tests fail, replace the circuit pack and repeat the test.</li> </ol> |

## Cabinet Temperature Query Test (#122)

This test queries for the status of the temperature and fan sensors in the cabinet. This test is run on the following maintenance objects:

- | [AC-POWER](#)
- | [CABINET \(Cabinet Sensors\)](#)
- | [CARR-POW \(Carrier Power Supply\)](#)
- | [EMG-XFER \(Emergency Transfer\)](#)
- | [POWER](#)

## Emergency Transfer Query Test (#124)

This test reports the state of the Emergency Transfer switch. The test passes if the switch is in a position where the system can control Emergency Transfer. The test fails if the switch is in a position where the system cot control Emergency Transfer. The system does not have control of Emergency Transfer within a cabinet if the switch is in the manual ON or manual OFF state.

This test runs on the following maintenance objects:

## OLS Recycle Test (#126)

The Off-Line Switcher (OLS) Recycle Test test is **destructive**.

This test removes power from the specified carrier and causes all circuit packs in the recycled carrier to be removed and inserted. These actions cause all calls originating from or terminating to circuit packs in this carrier to be dropped. The pair of OLSs in the specified carrier is recycled. Both OLSs in the carrier are turned off for 2 seconds and then back on again. After the OLSs have been turned back on, the test queries a PN's Maintenance circuit pack for the status of the pair of OLSs in the specified carrier. If both OLSs are on and functioning, then the test passes. If both OLSs are not on and functioning, the test fails, and BOTH OLSs are turned off.

This test is run on [CARR-POW \(Carrier Power Supply\)](#).

## OLS/Power Unit Query Test (#127)

This test is known as the Off-Line Switcher (OLS) Query Test for the following maintenance objects:

- 1 [CABINET \(Cabinet Sensors\)](#)
- 1 [CARR-POW \(Carrier Power Supply\)](#)
- 1 [RING-GEN \(Analog Ring Generator\)](#)

This test is known as the Power Unit Query Test for:

- 1 [AC-POWER](#)
- 1 [CABINET \(Cabinet Sensors\)](#)
- 1 [EMG-XFER \(Emergency Transfer\)](#)
- 1 [POWER](#)

This test queries the PN's Maintenance for the status of the pair of OLSs in the specified carrier. If both OLSs are on and functioning, then the test passes. If both are not on and functioning, it fails.

| Error Code | Test Result | Description / Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
|------------|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|            | FAIL        | <p><b>AC-POWERED SYSTEMS</b></p> <p>There is a problem with one or both OLSs on the tested carrier.</p> <ol style="list-style-type: none"> <li>1. For each OLS that has every status LED OFF, check the AC input to the OLS at the OLS outlet. If there is no AC, then check the appropriate fuses for the affected OLS. Replace open fuses. If the fuses open again or AC does not show up at the OLS outlet, then there is probably a power wiring problem in the cabinet.</li> <li>2. At this point, AC should be present at the OLS outlet. Enter <b>recycle carrier UUC</b>, where <i>UUC</i> is the appropriate cabinet and carrier, in an attempt to bring back the OLSs for this carrier. If the test passes, the trouble is cleared. If the test does not pass, one OLS or both in the tested carrier is defective. If only one OLS is defective, then the status LEDs on the healthy OLS will light green for a moment. When the recycle test determines that both OLSs are defective, the software will turn off power to both the good and defective OLSs. This will cause the status LED(s) on the good OLS to light red.</li> <li>3. Unplug both OLSs, and wait approximately 1-minute to allow the OLSs to cool down. Plug in the OLSs. If either OLS is operating properly (the status LEDs show green), replace the defective OLS(s). See <a href="#">CARR-POW (Carrier Power Supply)</a></li> </ol> |
|            |             | <b>2 of 5</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

|------------|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|            | FAIL        | <p><b>DC-POWERED SYSTEMS</b></p> <p>There is a problem with one or both port carrier power supplies on the tested carrier.</p> <ol style="list-style-type: none"> <li>1. For each port carrier power supply that has every status LED OFF, check the DC input to the port carrier power supply at the port carrier power supply outlet. If there is no DC, check the appropriate circuit breakers for the affected port carrier power supply. If the circuit breaker has tripped, reset the circuit breaker. If the circuit breaker trips again or if DC is absent at the port carrier's power supply outlet, there is probably a power wiring problem in the cabinet.</li> <li>2. At this point, DC should be present at the port carrier power supply outlet. Enter <b>recycle carrier UUC</b>, where <i>UUC</i> is the appropriate cabinet and carrier, to attempt to bring back the port carrier power supplies for this carrier. If the test passes, the trouble is cleared. If the test does not pass, either one port carrier power supply or both in the tested carrier is defective. If only one port carrier power supply is defective, the status LEDs on the healthy port carrier power supply will light green for a moment. When the recycle test determines that both port carrier power supplies are defective, the software will turn off power to both the good and defective port carrier power supplies. This will cause the status LED(s) on the good port carrier power supply to light red.</li> <li>3. Unplug both port carrier power supplies, and wait approximately 1-minute to allow the power supplies to cool down. Plug in the power supplies. If either power supply is operating properly (the status LEDs show green), replace the defective power supplies).</li> <li>4. If the replaced port carrier power supply(s) still do not operate properly, a circuit pack or a defective telephone connected to a circuit pack in the affected carrier could be causing an electrical load that is preventing the power supply from operating properly. Unseat every circuit pack in the carrier, and enter <b>recycle carrier</b>.</li> </ol> |
|            |             | <b>4 of 5</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |

**Table 334: OLS/Power Unit Query Test (#127) 5 of 5**

| Error Code | Test Result             | Description / Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|------------|-------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|            | FAIL<br><i>(cont'd)</i> | <ul style="list-style-type: none"> <li>a. If the recycle passes, the port carrier power supplies are healthy and the problem is with one of the circuit packs. Reinsert the circuit packs one at a time. If the status LED shows red after reinserting a circuit pack, replace the defective circuit pack. If the status LED still shows red, remove the amphenol connector on the back of the slot containing this circuit pack and enter <b>recycle carrier</b>. If the status LED shows green, the problem is with one of the telephones or the wiring to one of the telephones on this slot.</li> <li>b. If either port carrier power supply still shows a red status LED, check for bent pins and cable placement in the affected carrier. There are failures that can occur on the PN's Maintenance circuit pack that <i>will not</i> be detected by their respective maintenance, but that will cause many, if not every, environment test to fail. If many environment tests are failing, replace the suspect circuit pack, depending on the system configuration, and the test rerun.</li> </ul> |
|            | PASS                    | Both OLSs or power supplies in the tested carrier were found to be healthy by the PN's Maintenance circuit pack. If the status LEDs on both OLSs or power supplies are not showing green, the PN's MAINT circuit pack may have incorrectly reported the state of the OLSs. Resolve any alarms on these MOs.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|            |                         | <b>5 of 5</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

## Internal Looparound Test (#135)

**This test is destructive.**

The Internal Looparound Test loops the transmitted DS1 bit stream back into the board receiver. The loop occurs just before the DS1 facility interface. The test is highly destructive and can only be initiated by a **reset board location** command.

All of the trunks on the DS1 or UDS1 Interface circuit pack must first be busied out using the **busyout board location** command before the Internal Looparound Test can be executed. The test uses the Tone Generator and Tone Detector to exercise a bit pattern consistency test for all ports. If the transmitted and received bit patterns on a trunk are different, the test fails.

All trunks of the DS1 Interface circuit pack are restored to the in-service state after **release board location** is entered

This test is run on the following maintenance objects:

- | [DS1-BD \(DS1 Interface Circuit Pack\)](#)
- | [MG-DS1 \(DS1 Interface Media Module\)](#)
- | [UDS1-BD \(UDS1 Interface Circuit Pack\)](#)

|               | FAIL        | <p><b>DS1-BD:</b> DS1 Interface circuit pack failed the Internal Looparound test.</p> <ol style="list-style-type: none"> <li>1. Retry the command at 1-minute intervals up to 5 times.</li> <li>2. If the DS1 Interface circuit pack is a TN767, enter <code>list measurement ds1-log location</code> to read the error seconds measurement. Otherwise, skip this step.</li> <li>3. Verify that both of the DS1 link's endpoints are administered with the same signaling mode, framing mode, and line coding.</li> <li>4. Check the physical connectivity of DS1 Interface circuit packs and cable.</li> <li>5. Contact T1 Network Service to diagnose remote DS1 endpoint.</li> <li>6. If Steps <a href="#">2</a> to <a href="#">5</a> are OK and the problem recurs, escalate the problem.</li> </ol> <p><b>UDS1-BD:</b> The UDS1 Interface circuit pack failed the Internal Looparound test.</p> <p>If the UDS1 connects to a T1 network facility or another switch:</p> <ol style="list-style-type: none"> <li>1. Retry <code>reset board location</code> at 1-minute intervals up to 5 times.</li> <li>2. Enter <code>list measurement ds1-log location</code> to read the error seconds measurement.</li> <li>3. Verify that both endpoints of the DS1 link are administered using the same signaling mode, framing mode, and line coding.</li> <li>4. Check the physical connectivity of DS1 Interface circuit packs and cable.</li> <li>5. Contact T1 Network Service to diagnose the remote DS1 endpoint.</li> <li>6. Replace the local UDS1 Interface circuit pack and repeat the test.</li> </ol> <p>If the UDS1 connects to a line-side terminating device such as a PRI terminal adapter:</p> <ol style="list-style-type: none"> <li>1. Retry <code>reset board location</code> at 1-minute intervals up to 5 times.</li> <li>2. Enter <code>list measurement ds1-log location</code> to read the error seconds measurement.</li> <li>3. Verify that the switch DS1 and the line-side terminating device are administered using the same signaling mode, framing mode, and line coding.</li> <li>4. Investigate the maintenance status of the line-side terminating device. Obtain the error seconds measurement on the terminating device (if possible). Refer to the line-side terminating device operating manual for information.</li> <li>5. Check the physical connection of the UDS1 Interface circuit pack to the terminating device. Check premise distribution system (or intra-premise wiring) for physical connection failures. If the error seconds measurement is severe, investigate premise distribution system wiring for noise and distance limitation.</li> <li>6. Replace the local UDS1 Interface circuit pack, and repeat the test.</li> <li>7. Contact the vendor of the line-side terminating device to diagnose the equipment.</li> </ol> |
|               | PASS        | <p>The Internal Looparound test passed on every administered trunk.</p> <ol style="list-style-type: none"> <li>1. Enter <code>release board location</code> to put the trunks in the in-service state.</li> </ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 0             | NO BOARD    | See <a href="#">NO BOARD</a> for the repair procedures.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

## DS1 Tie Trunk Seizure Test (#136)

The DS1 Tie Trunk Seizure Test verifies the trunk’s signaling capability. The test is composed of two parts. The first part queries the circuit pack or media module for errors. The second part of the test sends a seizure message to the DS1 Interface circuit pack or media module and expects an active reply by the DS1 Interface circuit pack or media module. If the system does not receive any reply and the timer expires, the test fails.

This second part of this test **can** be run on a trunk if one of the following cases is true:

1. The trunk direction is administered as an incoming only trunk.
2. The trunk is the 24<sup>th</sup> port on a DS1 Interface circuit pack or media module which is administered using 24<sup>th</sup> common-channel signaling.
3. The trunk has been seized by a normal trunk call.
4. The trunk is administered with maintenance test disabled.
5. The outgoing signal type of the trunk is either automatic or immediate-start.

This test runs on [TIE-DS1 \(DS1 Tie Trunk\)](#).

## Loss of Signal Alarm Inquiry Test (#138)

**Note:**

The term "board" refers to the DS1 Interface circuit packs, UDS1 Interface circuit packs, and DS1 Interface Media Modules.

The Loss of Signal Alarm Inquiry Test verifies the synchronization status, echo cancellation, and continuity of the DS1 link.

A Loss of Signal Alarm indicates that the board is unable to derive the synchronization clock from the DS1 facility. If the board is administered as a timing source and it detects a Loss of Signal alarm, the board will stop providing the synchronization clock for the system and will transmit a Yellow alarm to the remote DS1 endpoint.

When the Loss of Signal alarm is confirmed, every trunk or port of the board is put into the out-of-service state. The inquiry test will run every 10 minutes until the loss of signal has been restored.

This test is run on the following maintenance objects:

- 1 [DS1-BD \(DS1 Interface Circuit Pack\)](#)
- 1 [MAPD-BD \(MAPD Interface Circuit Pack\)](#)
- 1 [MG-DS1 \(DS1 Interface Media Module\)](#)
- 1 [UDS1-BD \(UDS1 Interface Circuit Pack\)](#)

### 120A CSU Module/Sync Splitter

This test also maintains the 120A CSU module or the 401A T1 sync splitter, and the 402A or 403A E1 synchronization splitter. The CSU module, when combined with the functionality provided by the UDS1 circuit pack, provides functionality equivalent to an external stand-alone ESF T1 CSU. The combination of the UDS1 and 120A CSU module is known as an Enhanced Integrated CSU (I-CSU).

The 401A T1 synchronization splitter, when combined with the functionality provided by the UDS1 circuit pack, allows an ATM switch to derive its timing from a T1 connected to the UDS1 in the S8700 Fiber-PNC system.

The 402A or 403A E1 synchronization splitter, when combined with the functionality provided by the UDS1 circuit pack, allows an ATM switch to derive its timing from an E1 connected to the UDS1 in the S8700 Fiber-PNC system.

If a UDS1 circuit pack detects certain I-CSU/Sync Splitter hardware errors, it notifies the system. When the system receives notification of the I-CSU/Sync Splitter error, it executes the Loss of Signal Alarm Inquiry test (#138). The test queries for a Loss of Signal alarm condition, and queries the UDS1 board to confirm the I-CSU/Sync Splitter error. A Minor or Warning alarm is raised depending on the severity of the I-CSU/Sync Splitter error. The trunks on the board may be taken out of service if the I-CSU/Sync Splitter error is deemed serious.

## Maintenance Demand Tests

If a Loss Of Signal alarm and an I-CSU/Sync Splitter error coexist, the Loss Of Signal alarm condition takes priority, and the board and all of its trunks are put in the out-of-service state. Errors are logged for both.

When the system receives notification that the I-CSU/Sync Splitter hardware error condition no longer exists, maintenance restores the board and its trunks to their previous service state if the alarm can be cleared (no other I-CSU/Sync Splitter errors or Loss Of Signal alarms exist).

**Table 337: Loss of Signal Alarm Inquiry Test (#138) 1 of 7**

| Error Code | Test Result | Description / Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

## Blue Alarm Inquiry Test (#139)

**Note:**

The term "DS1 board" refers to the DS1 Interface circuit packs, the UDS1 Interface circuit packs, and the DS1 Interface Media Module.

A Blue Alarm is a signal sent by the remote DS1 endpoint when it is out-of-service. The Blue Alarm Inquiry Test checks the Blue Alarm status of the remote DS1 endpoint.

When a local DS1 board detects a Blue Alarm signal from the remote DS1 endpoint, it transmits a Yellow Alarm to the remote DS1 endpoint and sends a BLUE ALARM message to the system. When the Blue Alarm is confirmed, the system places all trunks or ports of the DS1 board into the out-of-service state. The inquiry test runs every 10 minutes until the Blue Alarm is cleared.

When the Blue Alarm is cleared, the DS1 board stops transmitting the Yellow alarm and places the trunks or ports back into the service state they were in before the Blue Alarm occurred

This test is run on the following maintenance objects:

- | [DS1-BD \(DS1 Interface Circuit Pack\)](#)
- | [MAPD-BD \(MAPD Interface Circuit Pack\)](#)
- | [MG-DS1 \(DS1 Interface Media Module\)](#)
- | [UDS1-BD \(UDS1 Interface Circuit Pack\)](#)

---

## Line Loopback Alarm

The Line Loopback (LLB) is used by the remote DS1 endpoint to put the DS1 board into a loopback mode. When the DS1 board is in the LLB mode, the arriving bit pattern is regenerated and sent back. The Line Loopback (LLB) Alarm activates when the in-band activate LLB bit pattern arrives continuously for 5 seconds on the DS1 line. The LLB deactivates when the in-band deactivate LLB bit pattern arrives continuously for 5 seconds on the DS1 line.

Since LLB is a condition rendering all DS0 channels unavailable for signaling or bearer traffic, the system treats this the same as a Blue Alarm.

---

## Payload Loopback Alarm

The Payload Loopback (PLB) is used by the remote DS1 endpoint to put the switch DS1 into a loopback mode. The PLB Alarm activates when a network protocol activate bit pattern arrives over the 4Kbps ESF data link on the DS1 line. The PLB deactivates when a network protocol deactivate bit pattern arrives over the 4Kbps ESF data link on the DS1 line.

## Maintenance Demand Tests

Since PLB is a condition rendering all DS0 channels unavailable for signaling or bearer traffic, the system treats this the same as a Blue Alarm.

## Red Alarm Inquiry Test (#140)

A DS1/UDS1 Interface circuit pack or DS1 Interface Media Module raises a Red alarm when the framing pattern of the incoming DS1 bit stream has been lost. The Red Alarm Inquiry test checks the framing status of a DS1 board.

When the DS1 board detects a Red Alarm, it transmits a Yellow Alarm to the remote DS1 endpoint and sends a Red Alarm message to the system. After the Red Alarm is confirmed, the system places every trunk or port of the DS1 board into the out-of-service state. The inquiry test runs every 10 minutes until the Red Alarm is cleared.

When the Red Alarm is cleared, the DS1 board stops transmitting the Yellow alarm to the remote DS1 endpoint. The system restores all trunks or ports of the DS1 board to the service state they were in before the Red Alarm occurred.

This test is run on the following maintenance objects:

- | [DS1-BD \(DS1 Interface Circuit Pack\)](#)
- | [MAPD-BD \(MAPD Interface Circuit Pack\)](#)
- | [MG-DS1 \(DS1 Interface Media Module\)](#)
- | [UDS1-BD \(UDS1 Interface Circuit Pack\)](#)

---

## Loss of Multiframe Alarm

If the DS1 circuit pack or media module is administered using DMI-BOS signaling, it raises a LMA (Loss of Multiframe Alarm) when it cannot interpret the incoming signaling bits to synchronize to the multiframe pattern received in the 24<sup>th</sup> channel. Once the DS1 board detects an LMA, the circuit pack transmits a RMA (Remote Multiframe Alarm) to the remote DS1 endpoint.

---

## Yellow Alarm Inquiry Test (#141)

The Yellow Alarm Inquiry Test determines whether the remote DS1 endpoint is transmitting a Yellow alarm. A Yellow Alarm indicates that the remote DS1 endpoint has an out-of-frame condition.

Once the Yellow alarm is confirmed, all trunks on the DS1 board are put into the out-of-service state. The Inquiry test will be run every 10 minutes until the Yellow Alarm is cleared. When the Yellow Alarm is cleared, all trunks on the DS1 board are restored back to their previous service state before the Yellow Alarm was raised.

The Yellow Alarm corresponds to the yellow F2 state documented in CCITT recommendation I.431.

This test is run on the following maintenance objects:

- 1 [DS1-BD \(DS1 Interface Circuit Pack\)](#)
- 1 [MAPD-BD \(MAPD Interface Circuit Pack\)](#)
- 1 [MG-DS1 \(DS1 Interface Media Module\)](#)
- 1 [UDS1-BD \(UDS1 Interface Circuit Pack\)](#)

## Remote Multiframe Alarm

A Remote Multiframe Alarm (RMA) indicates that the remote DS1 endpoint is in a Loss of Multiframe Alarm condition while the DS1 board is administered using the DMI-BOS common-channel signaling. The RMA is handled as a Yellow alarm.

## Yellow F5 State Alarm

For 32-channel E1 operation with CRC4 on, the F5 fault state is defined as a fault in the user-network interface, specifically in the direction from the user to the network. Refer to CCITT recommendation I.431

## Major Alarm Inquiry Test (#142)

The Major Alarm Inquiry Test determines if the received average DS1 bit error rate on the DS1 facility is greater than 1/1000. All trunks on the DS1 board are put in the out-of-service state if a Major Alarm lasts for more than 20 minutes.

When the Major Alarm is cleared, all trunks on the DS1 board are restored to their previous service state before the Major Alarm occurred.

This test is run on the following maintenance objects:

- 1 [DS1-BD \(DS1 Interface Circuit Pack\)](#)
- 1 [MAPD-BD \(MAPD Interface Circuit Pack\)](#)
- 1 [MG-DS1 \(DS1 Interface Media Module\)](#)
- 1 [UDS1-BD \(UDS1 Interface Circuit Pack\)](#)

## Minor Alarm Inquiry Test (#143)

The Minor Alarm Inquiry test determines if the received DS1 bit error rate is greater than 1/1,000,000 and less than 1/1000.

Every trunk or port on the DS1 board is kept in the in-service state after the Minor Alarm is confirmed. The Minor Alarm Inquiry test runs every 10 minutes until the Minor Alarm is cleared.

This test is run on the following maintenance objects:

- 1 [DS1-BD \(DS1 Interface Circuit Pack\)](#)
- 1 [MAPD-BD \(MAPD Interface Circuit Pack\)](#)
- 1 [MG-DS1 \(DS1 Interface Media Module\)](#)
- 1 [UDS1-BD \(UDS1 Interface Circuit Pack\)](#)

## Slip Alarm Inquiry Test (#144)

Slips occur when the transmitter and receiver are not running at precisely the same clock rate. The DS1/UDS1 Interface circuit pack or media module can detect both positive and negative slips on the DS1 facility. The Slip Alarm Inquiry Test displays the total number of slips that have occurred on a DS1 link if there are any.

Every trunk or port of the DS1 board remains in the in-service state. If the DS1 board supplies the system synchronization source, the MINOR alarm will initiate a synchronization source switch. See [TDM-BUS \(TDM Bus\)](#) and [SYNC \(Port Network Synchronization\)](#) for details.

This test is run on the following maintenance objects:

- 1 [DS1-BD \(DS1 Interface Circuit Pack\)](#)
- 1 [MAPD-BD \(MAPD Interface Circuit Pack\)](#)
- 1 [MG-DS1 \(DS1 Interface Media Module\)](#)
- 1 [UDS1-BD \(UDS1 Interface Circuit Pack\)](#)

## Misframe Alarm Inquiry Test (#145)

A Misframe Alarm indicates that framing bits observed on a DS1 board are in error. The Misframe Alarm Inquiry test queries the total number of misframes that have occurred on a DS1 board since the last inquiry.

If the DS1 board is supplying the system synchronization source when the threshold of misframes is reached, a switching synchronization source message is sent to the TDM bus Clock. See [TDM-BUS \(TDM Bus\)](#) for details. A Minor Alarm against the DS1 board is raised, but every trunk or port of the DS1 board remains in the in-service state.

This test is run on the following maintenance objects:

- 1 [DS1-BD \(DS1 Interface Circuit Pack\)](#)
- 1 [MAPD-BD \(MAPD Interface Circuit Pack\)](#)
- 1 [MG-DS1 \(DS1 Interface Media Module\)](#)
- 1 [UDS1-BD \(UDS1 Interface Circuit Pack\)](#)

**Table 344: Misframe Alarm Inquiry Test (#145)**

| Error Code | Test Result | Description / Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|------------|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|            | ABORT       | Internal system error<br>1. Retry the command at 1-minute intervals up to 5 times.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| 2000       | ABORT       | Response to the test was not received within the allowed time. This may be due to hyperactivity.<br>1. Enter <code>display errors</code><br>2. Check the Error Log for Error Type 1538. If Error Type 1538 appears in the error log for this board, see <a href="#">Hyperactive DS1/UDS1 Interface Circuit Pack/Media Module</a> for the repair procedures. Otherwise, retry the test at 1-minute intervals up to 5 times.                                                                                                                                                                                                                                                                                                                                                                                                |
| 2100       | ABORT       | Could not allocate the necessary system resources to run this test.<br>1. Retry the command at 1-minute intervals up to 5 times.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| ANY        | FAIL        | The DS1 board detected errors in the received framing bits pattern. The Error Code value is the number of misframes detected since the last misframe alarm inquiry test. Major bit and minor bit error rate (Error Types 2561 and 2817) errors often accompany misframe alarms. Clearing the cause of these errors may clear the misframes which are occurring.<br>1. Enter <code>list measurement ds1-log location</code> to read the error seconds measurement.<br>2. If the DS1/UDS1 circuit pack or media module connects to a T1 network facility or to another switch, see <a href="#">T1 Network Facility Procedures</a><br>3. If the DS1/UDS1 circuit pack or media module connects to a line-side terminating device such as a PRI terminal adapter, see <a href="#">Line-side Terminating Device Procedures</a> |
|            | PASS        | No Misframe Alarm is detected on the DS1 board.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 0          | NO BOARD    | See <a href="#">NO BOARD</a> for the repair procedures                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |
|            |             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

## DS1 Translation Update Test (#146)

The DS1 Translation Update Test sends the board-level information specified by System Administration to the DS1/UDS1 Interface circuit pack or media module. Translation includes the following data (see the output of `display ds1 location`): DS1 Link Length between two DS1 endpoints, Synchronization Source Control, All Zero Suppression, Framing Mode, Signaling Mode, Time Slot Number of 697-Hz Tone, Time Slot Number of 700-Hz Tone, etc.

If a DS1/UDS1 circuit pack is combined with a 120A CSU module or the 401A T1 sync splitter to screen an Integrated CSU module/T1 sync splitter, this test will also send the administration for the Integrated CSU to the circuit pack to assure the board's translations are correct. The administration of the CSU module/T1 sync splitter is done using the **DS1 Circuit Pack** administration screen. Translation for the CSU module/T1 sync splitter includes the following data: Transmit LBO, Receive ALBO, Supply CPE Loopback Jack Power.

This test is run on the following maintenance objects:

- 1 [DS1-BD \(DS1 Interface Circuit Pack\)](#)
- 1 [MAPD-BD \(MAPD Interface Circuit Pack\)](#)
- 1 [MG-DS1 \(DS1 Interface Media Module\)](#)
- 1 [UDS1-BD \(UDS1 Interface Circuit Pack\)](#)

## TDM Bus Clock Circuit Status Inquiry Test (#148)

This test checks the sanity of the TDM Bus Clock circuitry.

This test runs on the following maintenance objects:

- 1 [TDM-CLK \(TDM Bus Clock\)](#)
- 1 [TONE-BD \(Tone-Clock Circuit Pack\)](#)
- 1 [TONE-PT \(Tone Generator\)](#)

## TDM Bus Clock Slip Inquiry Test (#149)

This test queries the Tone-Clock circuit pack for timing slips.

This test is not applicable for TN2182, TN2312, or TN8412 circuit packs.

This test runs on the following maintenance objects:

- 1 [TDM-CLK \(TDM Bus Clock\)](#)
- 1 [TONE-BD \(Tone-Clock Circuit Pack\)](#)
- 1 [TONE-PT \(Tone Generator\)](#)

Table 347: TDM Bus Clock Slip Inquiry Test (#149) 1 of 2

| Error Code | Test Result | Description / Recommendation                                                                                                 |

## TDM Bus Clock PPM Inquiry Test (#150)

This test evaluates the quality of the synchronization source for the Tone-Clock circuit.

This test runs on the following maintenance objects:

- | [TDM-CLK \(TDM Bus Clock\)](#)
- | [TONE-BD \(Tone-Clock Circuit Pack\)](#)
- | [TONE-PT \(Tone Generator\)](#)

**Table 348: TDM Bus Clock PPM Inquiry Test (#150) 1 of 2**

| Error Code | Test Result | Description / Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

---

## TDM Bus Clock Parameter Update Test (#151)

This test updates the following internal parameters on the IPSI or Tone-Clock circuit pack:

- 1 Disables inline duplication status messages.
- 1 **S8700-series Fiber-PNC**: Disable inline subrate frame maintenance messages (TN768, TN780 only).
- 1 **S8700-series Fiber-PNC**: Sets the PPM threshold at 60 PPM for TN768 and TN780.  
Sets the PPM threshold at 85 PPM for TN2182 and TN2312.
- 1 Enables PPM threshold switching.
- 1 Sets the number of slips to trigger *loss of signal* - currently 30 per 5-millisecond period.
- 1 Enables the on-board synchronization switching algorithm (see above).
- 1 Enables holdover operation (TN2182 and TN2312 only).

This test always passes without identifying or reporting any IPSI or Tone-Clock circuit pack errors.

This test runs on the following maintenance objects:

- 1 [TDM-CLK \(TDM Bus Clock\)](#)
- 1 [TONE-BD \(Tone-Clock Circuit Pack\)](#)
- 1 [TONE-PT \(Tone Generator\)](#)

Table 349: TDM Bus Clock Parameter Update Test (#151)

| 1412       | ABORT       | This test does not run on media modules or media gateways. Ignore                        |
|            | FAIL        | Internal system error<br>1. Retry the command at 1-minute intervals up to 5 times.       |
|            | PASS        | The IPSI or Processor/Tone-Clock circuit pack parameters have been successfully updated. |

---

## Analog Looparound Test (#161)

The Analog Looparound Test checks the on-board transmission capabilities of the NPE, the codec, and the battery feed chip of the analog port. The test passes if the signal measured by the Tone Detector is within acceptable limits.

This test runs on the following maintenance objects:

- | [ADX16A-P \(AUDIX Analog Line/Control Link\)](#)
- | [AN-LN-PT \(Analog Line Port\)](#)
- | [ANL-16-L \(16-Port Analog Line\)](#)

Table 350: Analog Looparound Test (#161) 1 of 4

## Speech Synthesis DTMF Receiver Test (#163)

A series of dual-tone multifrequency (DTMF) tones are conferenced from the TDM bus into the port's DTMF receiver and checked to see if the correct tones have been detected during the correct intervals. If every DTMF tone was detected correctly, the test passes. If any of the tones were not detected correctly, the test fails.

This test runs on [S-SYN-PT \(Speech Synthesis Port\)](#).

**Table 351: Speech Synthesis DTMF Receiver Test (#163)**

## Speech Synthesis DTMF Sanity Inquiry (#164)

This test determines the sanity of the port's dual-tone multifrequency (DTMF) receiver. The on-board microprocessor tests the port's DTMF receiver and determines if it is in a sane (test passes) or insane (test fails) condition. This test runs on [S-SYN-PT \(Speech Synthesis Port\)](#).

**Table 352: Speech Synthesis DTMF Sanity Inquiry (#164)**

| Error Code   | Test Result | Description / Recommendation                                                                                                                                                                                                        |

| Any          | FAIL        | The DTMF receiver for this port is insane.<br>1. If the test fails again, replace the circuit pack.                                                                                                                                 |
|              | PASS        | The DTMF receiver for this port is sane. User-reported troubles should be investigated using other tests and by verifying other ports on this circuit pack are working correctly.                                                   |

## Speech Synthesis DSP Tone Test (#165)

The digital signal processor (DSP) associated with each port can generate a 440-Hz tone which can be detected by TN748 General-Purpose Tone Detector circuits. A 440-Hz tone is generated for 500 ms on a specified time slot which is being listened to by the detector circuit. If the detector determines the tone is present on the time slot, the test passes. Otherwise, it fails.

This test runs on [S-SYN-PT \(Speech Synthesis Port\)](#).

Replace any circuit packs containing faulty Tone Detector circuits, and repeat the test.<br>2. If the test fails again, replace the Speech Synthesis circuit pack.                                                                                                                                              |
|                      | PASS        | The 440-Hz tone has been detected correctly. User-reported troubles should be investigated using other tests and by verifying other ports on this circuit pack are working correctly.                                                                                                                                                                                                                                                                                                                                                                               |

## Speech Synthesis Memory Test (#166)

The encoded speech for the Speech Synthesis circuit pack is stored in on-board read-only memory (ROM). A checksum is computed for each 32K speech memory block and compared against a known checksum value. If every computed checksum value is successfully compared against the stored checksum values, the test passes. If, while testing the speech complex memory, the on-board microprocessor finds a memory error, the test is terminated and a failure is reported. This type of failure may affect other ports on the Speech Synthesis circuit pack, resulting in errors or alarms on each port.

This test runs on [S-SYN-PT \(Speech Synthesis Port\)](#).

## Speech Synthesis SSD Inquiry Test (#167)

This test determines the sanity of the specified port's speech synthesis device (SSD). The on-board microprocessor tests the port's SSD and determines if it is in a sane (test passes) or insane (test fails) condition. Other ports on the Speech Synthesis circuit pack will continue to function correctly during this type of failure.

This test runs on [S-SYN-PT \(Speech Synthesis Port\)](#).

Table 355: Speech Synthesis SSD Inquiry Test (#167)

| Error Code   | Test Result | Description / Recommendation                                                                                                                                                                                            |

|              | PASS        | The SSD is sane. Investigate user-reported troubles by using other tests and by verifying other ports on this circuit pack are working correctly.                                                                       |

## Speech Synthesis PSS Handshake Test (#168)

This test verifies control functionality between the on-board microprocessor and programmable speech synthesizer (PSS) controller. A failure occurs if either of the following events occur:

- 1. The on-board microprocessor times out while waiting for the PSS controller to respond.
- 1. An invalid command is received by the on-board microprocessor from the PSS controller.

This type of failure will affect all four ports on the Speech Synthesis circuit pack, resulting in errors or alarms on each port. This test runs on [S-SYN-PT \(Speech Synthesis Port\)](#).

**Table 356: Speech Synthesis PSS Handshake Test (#168)**

| Error Code   | Test Result | Description / Recommendation                                                                                                                                                                                                                                                                                                        |

## Speech Synthesis Parameter Update Test (#169)

This test updates the dual-tone multifrequency (DTMF) inter-digit time-out parameter used by the Speech Synthesis circuit pack so that it is consistent with that specified by the server.

This test runs on [S-SYN-PT \(Speech Synthesis Port\)](#).

**Table 357: Speech Synthesis Parameter Update Test (#169)**

| Error Code | Test Result | Description / Recommendation                                                                                                                                                                                                                                                                         |

---

## Digital Looparound Test (#171)

The Digital Looparound Test checks the data line port's ability to transmit and receive data on the TDM Bus. Data is sent through an available Maintenance/Test digital port over the TDM Bus, internally looped through the data line port back onto the TDM Bus, and received again by the same Maintenance/Test digital port.

Only one of the two digital ports on a Maintenance/Test circuit pack is used for this test. If port 02 is in use, out-of-service, or not present, the test aborts. This test may fail if the Maintenance/Test digital port used by the test is not functioning properly.

## Maintenance Demand Tests

If there are any M/T-DIG errors in the Error Log, see [M/T-BD \(Maintenance/Test Circuit Pack\)](#) and clear them first.

This test will pass regardless of any customer equipment that may be connected to the port, as long as the equipment is not using the port.

This test runs on [DAT-LINE \(Data Line Port\)](#).

**Table 358: Digital Looparound Test (#171) 1 of 4**

## Data Module Internal Looparound Test (#175)

This test verifies that a data message can be sent from the switch, through the building wiring, through an internal looparound path in the data module, and back to the switch. This path is illustrated below.

For this test to run, the **Remote Looparound Test** field on the Data Module administration screen must be set to **y**, indicating that the data module endpoint supports the test.

This test runs on [PDMODULE \(Processor Data Module\)](#) and [TDMODULE \(Trunk Data Module\)](#).

**Figure 98: Internal Looparound Test**

A signaling message is sent through the digital port circuit pack to the data module, requesting it to enter looparound mode. A test pattern is then sent from the TN771D Maintenance/Test circuit pack, over the path illustrated above, and back to the TN771D where it is checked for consistency.

The test aborts if any of the following local resources are not available:

- 1 A digital port on the TN771D. There are two such digital ports, but only one may be used at a time.
- 1 Two TDM time slots
- 1 An idle digital port connected to the data module

## Channel Administration Memory Array Test (#205)

The Channel Administration Memory Array (CAMA) Test checks the dual port RAM, which is used for storing control information for the 140AY. Patterns are written, read back, and verified. The test passes if the patterns match. The test fails if the patterns do not match.

This test runs on [-PT \(Announcement Port\)](#).

**Table 360: channel Administration Memory Array Test (#205)**

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

If there are recurring alarms on this port caused by this test failing, replace the circuit pack even if Step 1 works (see Warning).</li> </ol> <p>Replacing the circuit pack results in loss of integrated announcements. Refer to <a href="#">General notes</a>.</p> |
|            | PASS        | This test verifies that the Angel processor can properly set up this port for playbacks. Investigate user-reported troubles on this circuit pack using other port and circuit pack tests. Refer to <a href="#">-BD (Announcement circuit pack)</a> for a description of the circuit pack tests.                                                                                                                                                                                                                                                                        |

Notes:

- a. The announcement circuit pack can exhibit a condition that does not allow recording.

If the circuit pack gets locked into this state (this is an extremely rare condition), two of the announcement Ports on the circuit pack (one of which is the record port) is unusable by software. Also, **save/restore announcements** do not work because the record port looks busy to the circuit pack. The system does not have any way of knowing this and attempts to use the ports.

If the circuit pack is locked into this state, the following symptoms are observed:

- 1 When attempting to record an announcement, users hear the proper record tone, but the announcement does not record. They do not know it until the announcement is played back.
- 1 The command **test board location long** returns the following abort codes:
  - 1 Ports 1 AND 9 abort Test #206 with error code 1024
  - 1 Ports 1 AND 9 abort Test #205 with error code 2000
  - 1 Board level Tests #209 and #210 abort with error code 1024
- 1 **Save/restore announcements** times out with **Error encountered, can't complete request**

Clear the announcement circuit pack lock-up remotely by performing a soft reset on the circuit pack. Note that the busyout command drops all calls in progress on the announcement circuit pack.

---

## Playback Speech Memory Array Test (#206)

The Playback Speech Memory Array (PSMA) test checks the integrity of a playback channel's interface to the speech memory and the TDM Bus. The SP has an internal buffer that contains a specific 256-byte sequence. During this test, the byte sequence is "played" through the 140AY device onto the TDM Bus. A General Purpose Tone Detector is used to confirm that the proper sequence was played. This test is very important. It is the only test that actually checks an announcement Port's ability to play back an announcement on the TDM Bus. If the test fails, the Tone Detector returns the number of bytes that did not match the expected sequence. The larger the number, the more severe the problem with that port. If this test fails, announcements played over this port should sound corrupted.

It is the only test that actually checks an announcement Port's ability to play back an announcement on the TDM Bus. If the test fails, the Tone Detector returns the number of bytes that did not match the expected sequence. The larger the number, the more severe the problem with that port. If this test fails, announcements played over this port should sound corrupted.

This test runs on [-PT \(Announcement Port\)](#).

## Angel Speech Processor Handshake Test (#208)

This test checks the integrity of the communication link between the two processors on the announcement circuit pack. This test runs on [-BD \(Announcement circuit pack\)](#).

Failure of this test indicates that the Speech Processor is insane and results in the loss of all integrated announcements on the circuit pack.

**Table 362: Angel Speech Processor Handshake Test (#208)**

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

## Announcement Checksum Test (#209)

A checksum is associated with every recorded announcement. In this test, the Speech Processor (SP) checks a stored global checksum covering all recorded announcements against a calculated one and returns the results to the maintenance system. If the global checksum failed, the switch requests the SP to check the checksum of each individual announcement.

If the test fails, then it returns the total number of defective announcements found. In addition, associated with each failure is an error in the Error Log (Error Type 14). The Aux Data indicates the number of the first defective announcement found. This number corresponds to the announcement numbers on the announcement form. The extension relating to the announcement can be determined by `display announcement`.

This test runs on [-BD \(Announcement circuit pack\)](#).

Table 363: Announcement Checksum Test (#209) 3 of 3

| Error Code    | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|---------------|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0-256         | FAIL        | <p>The test failed. The error code indicates the total number of defective announcements that were found.</p> <p>Error code 0 indicates the Global Checksum failed on the board, but no individual Checksum failed.</p> <p><b>Note:</b></p> <p>Since the announcements are recorded digitally, it is possible for the announcement Checksum Test to <i>fail</i> but still have all the announcements sound uncorrupted. When an individual announcement fails the Checksum Test, always listen to the announcement first before taking any action. An announcement can be played back by dialing the announcement extension associated with the announcement number.</p> <ol style="list-style-type: none"> <li>1. Look in the Error Log to determine the number of the first defective announcement. Play back the announcement. If the announcement sounds defective, rerecord it or delete it. If the error code was greater than one, indicating that there is more than one defective announcement, run this test again and repeat this step.</li> <li>2. If the checksum test still fails after deleting and rerecording all defective announcements, reset the circuit pack with <b>reset board location</b> and run this test again.</li> <li>3. If the test still continues to fail, reseal the circuit pack and restore all announcements with an appropriate time estimate (for example, 40 minutes.) Then rerecord the lost announcements (that is, those recorded since the last save operation) and run this test again.</li> <li>4. If the test still continues to fail, replace the circuit pack, and run this test again.</li> </ol> <p>Replacing the circuit pack results in loss of integrated announcements. See <a href="#">General notes</a>.</p> |
|               | PASS        | <p>All recorded announcements checksum correctly, indicating that the speech main memory is functioning properly. User-reported troubles on this circuit pack should be investigated using other circuit pack and port tests. Refer to <a href="#">-PT (Announcement Port)</a> Maintenance documentation for a description of the port tests.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

## 140AY Looparound Test (#210)

This test checks the integrity of the record channel on the announcement circuit pack (Announcement Port 1).

Since this test involves sending a tone through two different ports, the [Playback Speech Memory Array Test \(#206\)](#) is run on the two ports first to make sure that they are working properly.

This test runs on [-BD \(Announcement circuit pack\)](#).

**Table 364: 140AY Looparound Test (#210) 1 of 3**

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

## Super Frame Match Inquiry Test (#211)

The super frame is a means by which the Speech Processor (SP) synchronizes with the 140AY device on the announcement circuit pack. If the super frame is not synchronized, the SP is not able to properly process record/playback requests. Both the SP and the hardware generate a super frame pulse. When these two pulses are out of synch, the SP sets a flag to indicate the mismatch. When this test is run, the state of this flag is returned.

This test runs on [-BD \(Announcement circuit pack\)](#).

**Table 365: Super Frame Match Inquiry Test (#211)**

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

## Clock Match Inquiry Test (#212)

This test determines the state of the clock generation circuitry on the announcement circuit pack. This circuitry is used for controlling various pieces of the hardware such as the 140AY device. It also synchronizes the announcement circuit pack with the clock that is on the backplane.

This test runs on [-BD \(Announcement circuit pack\)](#).

**Table 366: Clock Match Inquiry Test (#212)**

| Error Code | Test Result | Description/ Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

## Link Tear Down Test (#213)

**This test is destructive.**

This test disconnects the existing link between the system and the external output device. If the link has already been disconnected, this test just returns "PASS." Each resource allocated for an output device link is released after this test.

This test runs on the following maintenance objects:

- | [CDR-LNK \(Call Detail Recording Link\)](#)
- | [JNL-PRNT \(Journal Printer Link\)](#)
- | [PMS-LINK \(Property Management System Link\)](#)
- | [PMS-PRNT \(PMS Printer Link\)](#)
- | [PRI-CDR \(Call Detail Recording Link\)](#)
- | [SEC-CDR \(Call Detail Recording Link\)](#)

1 [SYS-PRNT \(System Printer\)](#)

**Table 367: Link Tear Down Test (#213)**

| Error Code | Test Result | Description / Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

## Link Retry Test (#215)

This test sends a message to the output device software process to make a data call to the extension where the output device connects. If the link is already up, this test passes without making any data call.

This test runs on the following maintenance objects:

- | [CDR-LNK \(Call Detail Recording Link\)](#)
- | [JNL-PRNT \(Journal Printer Link\)](#)
- | [PMS-LINK \(Property Management System Link\)](#)
- | [PMS-PRNT \(PMS Printer Link\)](#)
- | [PRI-CDR \(Call Detail Recording Link\)](#)
- | [SEC-CDR \(Call Detail Recording Link\)](#)
- | [SYS-PRNT \(System Printer\)](#)

**Table 368: Link Retry Test (#215) 1 of 2**

## Neon Test (#220)

This test checks the voltage required to light the neon lamp on an analog terminal. A relay connects a 150V DC source from the backplane of the circuit pack onto the voltage bus, and another relay connects a 2K shunt from the bus to ground. Current in the line is then monitored to determine if the voltage is present.

This test runs on [XXX-BD \(Common Port Circuit Pack/Media Module\)](#).

**Table 369: Neon Test (#220) 2 of 3**

| Error Code    | Test Result | Description / Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
|---------------|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1018          | ABORT       | <p>There are no translated ports on the circuit pack. If ports are translated, none are administered to have "neon."</p> <ol style="list-style-type: none"> <li>1. Verify there are ports administered on the circuit pack. If no ports are administered, no further action is required.</li> <li>2. Verify that neon sets are connected. If there are no neon sets connected to the circuit pack, at least one port needs to be translated with neon. To check if a port is translated with neon, use <b>display port location</b> to determine the station extension of any station on this circuit pack. Enter <b>display station extension</b> to determine if the port is administered with neon. The field "Message Waiting Indicator:" must be set to "neon" for at least one of the administered ports. If this field is not administered to "neon", the test continues to abort. This is acceptable because not all stations have neon lamps on their analog terminals. If none of the terminals have neon lamps, the test continues to abort, and no further action is required.</li> <li>3. Retry the command at 1-minute intervals a maximum of 5 times.</li> <li>4. If the test continues to abort, look for <a href="#">RING-GEN (Analog Ring Generator)</a> errors in the Error Log. If an ABORT 1008 occurs for this test on other circuit packs as well, then the ringing generator may be defective. If ABORT 1008 does not occur on Test #48 for ANL-16-L, all four ring phases are in use.</li> <li>5. Retry the command again.</li> </ol> |
| 1412          | ABORT       | This test does not run on media modules or media gateways. Ignore.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
| 2000          | ABORT       | Response to the test was not received within the allowed time.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

## MTP SAT Channel Local Looparound Test (#228)

**This test is destructive.**

This test checks TN775D on-board circuitry associated with the serial link for the management terminal connection. This test will not cause the local terminal login to drop, but any data displayed on the terminal while the test is running will be lost.

The PN's Maintenance circuit pack has three separate serial interfaces, one for each of the following:

- 1 Management terminal - tested by Test #228
- 1 Active EI circuit pack - tested by Test #229
- 1 Standby EI circuit pack - tested by Test #229

This test runs on [MAINT \(PN Maintenance Circuit Pack\)](#).

|                      | PASS        | The serial interface circuitry on the PN's Maintenance circuit pack which controls the PN-connected terminal is functioning properly. If there are still troubles with the PN G3-MT terminal, the problem may be one of the following:<br>1. The PN-connected terminal is not configured properly. The connection between the terminal and the PN's Maintenance circuit pack must be set up at 9600 bps.<br>2. The serial link from the back of carrier A to the PN terminal may be defective. The serial link consists of the connector on the back of carrier A labeled TERM and the ribbon cable running to the terminal.<br>3. The terminal may be defective. Try another terminal.<br>4. Since this test is not 100 percent accurate, there may still be problems with the PN's Maintenance circuit pack. |

---

## Serial Channel Local Looparound Test (#229)

This test checks TN775D on-board circuitry associated with the serial links to the Expansion Interface circuit packs.

## Maintenance Demand Tests

The PN's Maintenance circuit pack has 3 separate serial interfaces, one to each of the following:

- 1 Management terminal - tested by Test #228
- 1 Active EI circuit pack - tested by Test #229
- 1 Standby EI circuit pack - tested by Test #229

A request is sent to the PN's Maintenance circuit pack over the active link. If a response is received, the serial interface circuitry associated with the active link is working properly.

This test runs on [MAINT \(PN Maintenance Circuit Pack\)](#).

## Expansion Interface Neighbor Query Test (#237)

The Expansion Interface Neighbor Query test is a request to an EI circuit pack to determine whether it has established communication with its neighbor EI or SNI circuit pack at the opposite end of the fiber.

For EI-to-EI fiber links, this test is run on both EI circuit pack endpoints of the fiber link. It runs on [EXP-INTF \(Expansion Interface Circuit Pack\)](#) and [FIBER-LK \(Fiber Link\)](#).

## Expansion Interface Fiber Out-of-Frame Query Test (#238)

This test is a request to an EI circuit pack to determine if it is can detect the framing sequence on the incoming fiber's data stream. If it cot detect this framing signal, the EI circuit pack will not be able to establish a link with the opposite EI or SNI circuit pack.

## Maintenance Demand Tests

For EI-to-EI fiber links, this test is run on both EI circuit pack endpoints of the fiber link. This test runs on [EXP-INTF \(Expansion Interface Circuit Pack\)](#) and [FIBER-LK \(Fiber Link\)](#).

| 1033       | ABORT       | The EI circuit pack does not have a fiber link administered to it. There is not sufficient data to run test. Because <code>test fiber-link</code> was run, the expansion interface should be administered on a fiber link, therefore this must be a software problem.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

## Expansion Interface Local Looparound (#240)

The EI local looparound test is similar to the Lightwave Transceiver Looparound test (#242). A test tone is received by the EI being tested, but is not transmitted out to the fiber interface before being looped back. The loopback is internal to the circuit pack. This test does not interfere with the normal fiber data stream.

This test runs on [EXP-INTF \(Expansion Interface Circuit Pack\)](#).

Table 375: Expansion Interface Local Looparound Test (#240) 1 of 4

| Error Code    | Test Result | Description / Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|---------------|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1             | ABORT       | Could not allocate time slot on TDM Bus A. Loopback passed on TDM Bus B.<br>1. If there is no reason to doubt that the EI circuit pack can transfer data to or from a TDM Bus, then since the test passed on one bus, assume that the test passes on the other bus.<br>2. If this test continues to abort with the same error, rerun test at 1-minute intervals up to 3 times.<br>3. If the test still does not pass on the other TDM Bus, follow the procedure for ABORT Error Code 3. |

## Expansion Interface 2-Way Transmission Test (#241)

**Note:**

The term EI applies to both the Expansion Interface (EI) and ATM Expansion Interface (ATM-EI) boards.

This test is nondestructive and applies to each EI, both active and standby.

The EI 2-way transmission test is a basic connectivity test between two PNs. The test first sends dial tone from the cabinet of the EI circuit pack under test through the switch, through the DS1 converter circuit packs, and through another EI circuit pack to a tone detector in the other cabinet. The connections are then reversed and the tone is passed in the opposite direction.

If the test either fails or aborts with the above connection, a second PN is chosen (if one is available and the EI circuit pack is In-Service) and the same test is run on this new connection. This helps in the isolation of the fault. Since two EI circuit packs are involved in the connection, either one of them could be at fault. This test can help determine which one is actually at fault.

The test results indicate if the test failed in one or both directions. The test aborts if the EIs do not exist on both ends (for example, the EIs are not administered correctly). If the test passes, the TDM and ATM framer interfaces of both EIs are functioning properly.

This test runs on [ATM-EI \(Expansion Interface Circuit Pack\)](#) and [EXP-INTF \(Expansion Interface Circuit Pack\)](#).

## Expansion Interface Lightwave Transceiver Looparound Test (#242)

**This test is destructive.**

This test requires that the EI circuit pack first be busied out. If the system has a duplicated Port Network Connectivity, this test can be run on an EI circuit pack that resides on the current active PNC due to restrictions that prohibit the busying-out of certain components that are part of the active PNC. If this test is run on an EI circuit pack that is part of the standby PNC, this test is not destructive and no service outages will take place.

In a system without duplicated Port Network Connectivity, where this EI circuit supports an IPSI to PN link, this test will disrupt service to one or more PN's. If the EI circuit pack is part of a PN-to-PN link in a Direct Connect system, service between the two PNs will be disrupted.

This is a 2-part connectivity test. In the first part of the test, a digital count is transmitted from the cabinet of the EI circuit pack under test, through the EI circuit pack under test, out to its lightwave transceiver. The connection then loops back into the lightwave transceiver, through the same EI circuit pack again, and into the originating cabinet. If the test tone is detected by a tone detector, the first part of the test passes. The path used for this part of the test is represented in [Figure 99: TDM BUS Lightwave Transceiver Looparound](#).

In the second part of the test, a data packet is sent from the TN1655 Packet Interface circuit pack to the EI circuit pack under test, the packet is looped back through the lightwave transceiver and is sent back to the Packet Interface circuit pack. If the Packet Interface circuit pack receives the same packet it transmitted, the second part of the test passes. If the entire test has passed, the EI circuit pack, its backplane wiring, and the electrical portion of the lightwave transceiver are healthy. The path used for this test is represented in [Figure 100: Packet Bus Lightwave Transceiver Looparound—PN only](#). The path used for this test if the EI resides in a PN is represented in [Figure 101: Packet Bus Lightwave Transceiver Looparound—CSS and PN](#).

When the EI circuit pack under test is in a PN, the data packet must also pass through the active EI circuit packs and the active DS1 converter circuit packs (and the active SNI circuit pack(s) in a Center Stage Switch system) of the active PNC link connecting the PN.

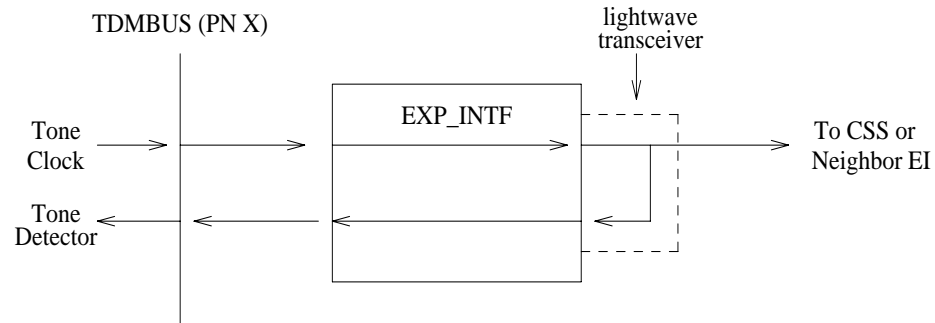

## Expansion Interface Lightwave Transceiver Looparound Test (#242)

This test requires the EI circuit pack to ignore incoming data from its neighbor EI circuit pack or SNI circuit pack. Thus this test will:

- 1 Disturb any inter-PN connections that currently exist over the link provided by the EI under test and its neighbor
- 1 Disrupt signaling between the two circuit packs

## Circuit Pack Restart Test (#252)

**This test is destructive.**

This test is not part of either the short or long demand test sequence.

Run this test to reset the circuit pack only if there are PPCPU errors. This test fails if the circuit pack does not return to a sane state after being reset. The circuit pack is reset by the SAKI Sanity test (#53).

This test runs on [CLAN-BD \(Control LAN Circuit Pack\)](#).

## Signaling Link State Audit Test (#255)

This test checks the state of critical signaling link hardware components such as DS1 and ATM CES circuit packs as required by the port.

This test runs on the following maintenance objects:

- 1 [ATM-BCH \(ATM B-Channel Trunk\)](#)
- 1 [ISDN-TRK \(DS1 ISDN Trunk\)](#)
- 1 [\\_PE \(Processor Ethernet\) Alarms](#)

**Table 379: Signaling Link State Audit Test (#255) 1 of 2**

| Error Code | Test Result | Description / Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

## Service State Audit Test (#256)

This test performs a service state audit with the far-end terminal adapter to ensure both sides agree on the service state.

If no reply is received within 2 minutes, the system will automatically try once again. If that attempt fails, an error will be logged (Error Type 3073) and the system will then attempt recovery by automatically retrying approximately every 15 minutes. If the port was initially in the INS (in-service) state, it will now be placed in the MTC/FE (maintenance state, far-end problem) state. Until a Service State audit attempt is successful, no outgoing calls will be placed over this port, but incoming calls will be accepted. The service state of this port does not affect the service state of other ports. If an incoming call that uses this port is presented while in such a state, a Service State audit attempt will immediately be attempted (that is, the system will not wait for the 15-minute cycle, but will instead try to recover immediately).

PASS for this test only means that a message to the far end was successfully sent.

To check the service state of an ATM-BCH port or TBRI-TRK ISDN BRI channel, enter `status trunk grp#/mem#`.

To check the service state of a PRI endpoint port, enter `status pri-endpoint extension`.

This test is run on the following maintenance objects:

## Maintenance Demand Tests

- | [ATM-BCH \(ATM B-Channel Trunk\)](#)
- | [ISDN-TRK \(DS1 ISDN Trunk\)](#)
- | [PE \(Processor Ethernet\) Alarms](#)
- | [TBRI-TRK \(ISDN Trunk-Side BRI Channel\)](#)

|               | PASS        | Wait 4 minutes, then check the Error Log for any new errors of type 3073.<br>1. If there are no new errors of type 3073, then both sides of the ISDN connection agree on the service state. The negotiation succeeded.<br>2. If there is a new error of type 3073, the negotiation failed. The system will automatically retry approximately every 15 minutes. If the port was initially in the INS (in-service) state, it will now be placed in the MTC/FE (maintenance, far-end problem) state. Incoming calls will be accepted, but no outgoing calls will be originated this port. If an incoming call is presented, another Service State audit will be immediately performed in an attempt to bring the port into the proper state. |
| <b>2 of 2</b> |             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

## Call State Audit Test (#257)

This test audits internal call state data by querying the far-end terminal adapter as to the ISDN state of the call. This can be helpful when trying to clear a hung call. If a call is active on the port, the switches on both sides of the connection should agree on the ISDN state of the call as defined in the ISDN Protocol Specification. If the internal call state data on the near-end switch is different than that of the far-end terminal adapter, the call will be torn down.

The ISDN specification allows up to 2 minutes for a reply. If a reply is not received within the 2 minute window, the test logs a protocol time-out violation against the associated signaling channel (Error Type 1 for ATM-DCH, ISDN-PLK).

This test is run on the following maintenance objects:

- | [ATM-BCH \(ATM B-Channel Trunk\)](#)
- | [ISDN-TRK \(DS1 ISDN Trunk\)](#)
- | [PE \(Processor Ethernet\) Alarms](#)
- | [TBRI-TRK \(ISDN Trunk-Side BRI Channel\)](#)

---

## ISDN Test Call Test (#258)

This test performs a far-end looparound test over an ISDN trunk if:

- 1 The trunk is in-service, maint-NE, or out-of-service/NE.
- 1 No calls are active on the trunk.

## Maintenance Demand Tests

- 1 The system uses country protocol 1 (including US), or the far end has looparound capability.

The test sets up a call to a far-end switch over the trunk to be tested. If a Maintenance/Test circuit pack does not reside in the system, the test call connection is established over the TDM Bus of the transmit and receive sides of the ISDN-PRI trunk to a data channel.

If a Maintenance/Test circuit pack does reside in the system, the test call connection is established over the TDM Bus of the transmit and receive sides of the ISDN-PRI trunk to a digital trunk testing port on the Maintenance/Test circuit pack. The digital port on a TN771D Maintenance/Test circuit pack sends a bit pattern to the far end which is echoed back. If the received pattern matches the pattern that was sent, the test passes. If there are differences, the test fails.

If a test call is running when scheduled maintenance starts, the green LED is turned off. To determine whether a test call is still running:

- 1 Enter `list isdnpri-testcall` and `status isdnpri-testcall`.
- 1 Check for a lit amber LED on the Maintenance/Test circuit pack.

## Synchronous Test Calls

Enter one of the following commands to initiate a synchronous outgoing test call:

- 1 `test trunk grp#/mem# long [repeat #]`
- 1 `test board location long [repeat #]`
- 1 `test port location long [repeat #]`

The duration of the test call is 8.6 seconds for unrestricted (B8ZS) B-Channels and 9.4 seconds for restricted (ZCS) B-Channels. The test fails if the bit error rate retrieved from the Maintenance/Test digital port is greater than 0. When this occurs, perform further diagnostics such as `test isdnpri-testcall`.

## Asynchronous Test Calls

You can start, query, and stop an outgoing test call by using the following commands:

- 1 `test isdnpri-testcall grp#/mem# [minutes #]`

This command initiates an outgoing ISDN-PRI test call up to 120 minutes. Default times are as above. Only one trunk per PN can be tested at one time.

- 1 `status isdnpri-testcall grp#/mem#`

This command displays the progress of the outgoing test call by reporting bit and block error rates of the tested B-Channel.

- 1 `clear isdnpri-testcall grp#/mem#`

This command terminates an outgoing test call already in progress. Measurements already collected are not cleared until the next test call begins.

A PASS of the asynchronous test indicates only that the test call was successfully established. Enter `status` and `list` to get the results of the test.

**Note:**

Before attempting to make an ISDN-PRI test call to the public network (that is, the network of the far end), make sure that test call service is provisioned by the network. The user must subscribe to Test Type 108 service and have the correct far-end test call number administered on the trunk group form for the call to be allowed.

Only one trunk can be tested in a given port network, until the test call is canceled or completes.

This test is run on the following maintenance objects:

- 1 [ATM-BCH \(ATM B-Channel Trunk\)](#)
- 1 [ISDN-TRK \(DS1 ISDN Trunk\)](#)
- 1 [TBRI-TRK \(ISDN Trunk-Side BRI Channel\)](#)

## Clear Error Counters Test (#270)

This test is not an actual test in the strict sense of the word. Many circuit packs have counters in the Angel firmware. These counters are used so that Control Channel Message Set (CCMS) messages are not continuously sent uplink to maintenance software. Using this method, the message will be sent until the counter reaches some preset threshold, then not sent again until the counter is cleared.

The ports on the circuit pack continually run self-tests whenever the port is idle. This test clears the counter so that if the port continues to fail during or after testing, the Angel will send a message to indicate that fact.

This test is only used to send a downlink message to the Angel on the circuit pack. Since the Angel normally provides no uplink response to this message, this test should never abort or fail.

This test is run on the following maintenance objects:

- 1 [ASAI-PT \(ASAI Port\)](#)
- 1 [BRI-PORT \(ISDN-BRI Port\)](#)
- 1 [M/T-ANL \(Maintenance/Test Analog Port\)](#)
- 1 [M/T-DIG \(Maintenance/Test Digital Port\)](#)
- 1 [M/T-PKT \(Maintenance/Test Packet Bus Port\)](#)
- 1 [TBRI-PT \(ISDN Trunk-Side BRI Port\)](#)

## Idle Time Slot Test (#294)

The Idle Time Slot test detects noisy time slots on the bus and takes them out-of-service. The Tone Detector circuit is told to listen to idle time slots. If it detects any noise on a time slot, it returns a failure. At the end of the test, any out-of-service time slots are retested to see if they are still noisy and are restored to service if they are idle. After every time slot has been tested, the number of bad time slots are reported in the Error Code field. No more than 220 time slots will be taken out-of-service on one bus, and no more than 300 will be taken out-of-service on both buses at one time.

This test runs on [TDM-BUS \(TDM Bus\)](#).

**Table 384: Idle Time Slot Test (#294)**

| Error Code | Test Result | Description / Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

## Control Channel Test (#296)

The Control Channel Test tests the integrity of the Control Channel bus by ensuring that communication through the TDM bus is operational. The test attempts to query a Tone-Clock or Tone Detector circuit pack which is required in each port network for proper operation. If a reply from the queried circuit pack is received, the TDM bus is considered operational and the test passes. If no reply is received, the TDM Bus is not operational and the test fails.

This test runs on [TDM-BUS \(TDM Bus\)](#).

**Table 385: Control Channel Test (#296)**

| Error Code          | Test Result | Description / Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

## Non-control Channel Test (#297)

The Non-control Channel Test is executed on the non-control channel bus. The Tone-Clock circuit puts a tone on the non-control channel bus and the Tone Detector circuit listens to it. The test passes if the tone is successfully transmitted on the non-control channel bus.

This test runs on [TDM-BUS \(TDM Bus\)](#).

**Table 386: Non-control Channel Test (#297)**

| Error Code           | Test Result | Description / Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

## PN Maintenance Circuit Pack Sanity Maze Test (#303)

The processor on the PN's Maintenance circuit pack has direct access to special registers in the Maintenance circuit pack. These registers are tied to such things as the Expansion Interface circuit pack reset leads and Carrier Port Power Unit reset leads which enable the PN's Maintenance circuit pack to recycle carriers. To prevent an insane Maintenance circuit pack from inadvertently controlling these external devices, a special interface called the Sanity Maze is provided. There are two parts to the test. Part 1 involves navigating the Sanity Maze to toggle an unused lead. Part 2 attempts to toggle an unused lead without first navigating the Sanity Maze. The Sanity Maze test passes if Part 1 is successful and Part 2 fails.

This test runs on [MAINT \(PN Maintenance Circuit Pack\)](#).

|            | PASS        | The Sanity Maze is working properly, and the PN's Maintenance circuit pack can access the unused register. If <b>recycle carrier</b> for PN carriers does not work, the following problems may still exist:<br>1. The Carrier Port Power Unit or wiring to the Carrier Port Power Unit may be defective. See <a href="#">CARR-POW (Carrier Power Supply)</a> .<br>2. Since this test only tests the PN, there is a very small probability that the PN's Maintenance circuit pack cannot access those registers that deal with PN devices. The Maintenance circuit pack may need to be replaced. |

## Expansion Interface Lock Query Test (#304)

The Expansion Interface Lock Query Test queries the ATM EI circuit pack for its status concerning a lock to the backplane system clock. The test passes if the response is "in lock". The test fails if the response is "out of lock". This test runs on [ATM-EI \(Expansion Interface Circuit Pack\)](#).

**Table 388: Expansion Interface Lock Query Test (#304) 1 of 2**

| Error Code    | Test Result | Description / Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

## PN Maintenance Circuit Pack Reset Test (#306)

**This test is destructive.**

The terminal connection will be dropped. If the Emergency Transfer switch is in the AUTO position, Emergency Transfer will be disabled for the duration of the test.

The PN's Maintenance circuit pack is reset by the active Expansion Interface circuit pack. After the Expansion Interface circuit pack reports that the PN's Maintenance circuit pack has reset, a handshake message is sent to the Maintenance circuit pack. If the Maintenance circuit pack responds to the handshake, the test passes. If not, it fails. If the test passes, the PN-connected terminal is brought back up, and Emergency Transfer is restored to its previous state.

This test runs on [MAINT \(PN Maintenance Circuit Pack\)](#).

Table 389: PN Maintenance Circuit Pack Reset Test (#306) 2 of 3

| Error Code   | Test Result | Description / Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|--------------|-------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1204<br>1205 | FAIL        | <p>Response not received from the circuit pack.</p> <p>EI circuit pack could not reset the PN's Maintenance circuit pack.</p> <p><i>For duplicated Port Network Connectivity:</i></p> <ol style="list-style-type: none"> <li>1. The standby EI circuit pack may be defective, preventing the active EI circuit pack from resetting the PN's Maintenance circuit pack. Unplug the standby EI circuit pack, and try to reset the Maintenance circuit pack with <b>test maint long</b>. If Test #306 passes, replace the standby EI circuit pack and attempt the reset test again. If Test #306 fails, replace the standby PN EI circuit pack.</li> <li>2. The active EI circuit pack may be defective and unable to reset the PN's Maintenance circuit pack. Interchange the PNC with <b>reset pnc interchange</b>. Reset the Maintenance circuit pack again with <b>test maintenance long</b>. If the test passes, the problem is with the known standby EI circuit pack. Repeat Step 2 to determine whether the standby EI circuit pack should be replaced.</li> <li>3. Replace the PN's Maintenance circuit pack and run the test again. If the test passes, the problem is with the Maintenance circuit pack. Interchange the PNC with <b>reset pnc interchange</b>, and run the test again. The test should pass with both EI circuit packs being active.</li> <li>4. If the B carrier EI circuit pack is active, the ribbon cable connecting the Expansion Interface circuit pack and the PN's Maintenance circuit pack may be defective. Check the ribbon cable to make sure it is connected properly and is not damaged.</li> </ol> <p><i>For unduplicated Port Network Connectivity:</i></p> <ol style="list-style-type: none"> <li>1. Replace the PN's Maintenance circuit pack and run the test again. If it passes, the problem is with the Maintenance circuit pack.</li> <li>2. If the test fails, replace the EI circuit pack. If the tests passes, the problem is with the EI circuit pack.</li> <li>3. If the test still fails, the problem is with the serial link wired into the backplane of carrier A.</li> </ol> |
|              |             | <b>2 of 3</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

**Table 389: PN Maintenance Circuit Pack Reset Test (#306) 3 of 3**

| Error Code    | Test Result | Description / Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|---------------|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2005          | FAIL        | <p>PN Maintenance Circuit Pack reset passed but the PN's Maintenance circuit pack did not respond to the subsequent handshake message. Retry this command three more times. If it continues to fail, the Maintenance circuit pack, the active EI circuit pack, or the serial link is defective. To determine which is defective:</p> <p><i>For Duplicated Port Network Connectivity:</i></p> <ol style="list-style-type: none"> <li>1. Interchange PNCs by entering <code>reset pnc interchange</code>.</li> <li>2. Run the short test sequence against the PN's Maintenance circuit pack. If Test #306 still fails, replace the Maintenance circuit pack and retest. Otherwise, follow the error procedures for any errors that are logged by this short test sequence.</li> </ol> <p><i>For Unduplicated Port Network Connectivity:</i></p> <ol style="list-style-type: none"> <li>1. Replace the PN's Maintenance circuit pack and invoke the short test sequence against it.</li> <li>2. If the error persists, replace the EI circuit pack at a time when the PN can go down with minimal inconvenience.</li> <li>3. If the error still persists, the problem is with the actual serial link in A carrier backplane and not with the PN's Maintenance circuit pack.</li> </ol> |
|               | PASS        | <p>The active EI circuit pack can reset the PN's Maintenance circuit pack. This implies the Maintenance circuit pack, the active EI circuit pack, and active serial link are sane. There could still be a problem with the standby EI circuit pack and standby serial link in a Duplication Option system.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>3 of 3</b> |             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

## Battery Holdover Hardware Verification Test (#311)

The hardware/firmware vintage of the PN's TN775D Maintenance boards does not support battery holdover for *all carriers*. This test checks to see if PN cabinet battery holdover for *all carriers* has been administered in error. If battery holdover is administered for *all carriers*, the test will fail and an alarm will be raised against this MO.

This test runs on [MAINT \(PN Maintenance Circuit Pack\)](#).

## DS1 OPS Switchhook Inquiry Test (#312)

This test queries the switchhook state of the Off-Premises-Station in switch software. If the state in switch software disagrees with the state on the DS1 Interface circuit pack, then the state in the switch software is updated to match the state on the DS1 Interface circuit pack.

This test runs on [OPS-LINE \(DS1 Off-Premises Station Line\)](#).

## DS1 CO Trunk Dial Tone Seizure Test (#314)

This test checks the trunk's signaling capability provided by the DS1 Interface circuit pack. The test sends a "seizure" message to the DS1 Interface circuit pack and expects an "active" reply in return. The test passes if the "active" message is received. It aborts if no message is received. It fails if the DS1 Interface circuit pack returns a "reorder" message.

This test can be run on a trunk in any of the following conditions:

1. The trunk direction is administered as an incoming only trunk.
2. The trunk has been seized by a normal trunk call.
3. The trunk is administered with maintenance test disabled.
4. The trunk is on a port of a DS1 Media Module.

This test runs on the following maintenance objects:

1. [CO-DS1 \(DS1 CO Trunk\)](#)

I [DIOD-DS1 \(DS1 DIOD Trunk\)](#)

## Expansion Interface Control Channel Test (#316)

If an ATM-EI or EI circuit pack is an *active* ATM-EI or EI in the PN (amber LED on long/off short), the Expansion Interface Control Channel test checks to see if the ATM-EI or EI circuit pack can communicate with other circuit packs in the PN using the PN's TDM bus.

If the circuit pack is a standby ATM-EI or EI (amber LED off), this test queries the circuit pack for its type and vintage information. This test runs on [ATM-EI \(Expansion Interface Circuit Pack\)](#) and [EXP-INTF \(Expansion Interface Circuit Pack\)](#).

**Table 393: Expansion Interface Control Channel Test (#316) 1 of 2**

| Error Code    | Test Result | Description / Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |

## Expansion Interface Reset Test (#336)

**This test is destructive.**

The Expansion Interface Reset test is executed using **reset board location**, where *location* is the location of the EI circuit pack to be reset. This test is potentially very destructive and requires the EI circuit pack to be busied out prior to execution of this test.

If the system does not have duplicated PNC, and is a Direct Connect system, and one of the EI circuit packs must be reset, the action of busying out the desired EI circuit pack will deny calls to the PN until the EI circuit pack is released from the busyout state. If the EI circuit pack is part of a PN-to-PN link, new connections to the PN will be denied. If the EI circuit pack is part of a PN-to-PN link, calls between the two PNs will be denied.

In a non-duplicated PNC system with a Center Stage Switch, if the EI circuit pack in the PN is busied out, new service to that PN only will be denied. However, if the EI circuit pack resides in the PN, new service to every PN will be denied until the EI circuit pack is released from the busyout state.

If the system does not have duplicated PNC, the reset of any EI is allowed, but it will result in the resetting of every PN board and loss of service to the PN(s) for a few minutes.

If the system does have duplicated PNC, and the EI circuit pack to be reset is part of the active PNC, the system will not allow the busyout and the system technician will be required to interchange the PNCs using **reset pnc interchange**. After executing the PNC interchange, it will be possible to busyout and then reset the original EI circuit pack.

If the PN's Maintenance (MAINT) circuit pack determines that the EI (EXP-INTF) circuit pack is cycling between sane and insane several times within several minutes, MAINT may inhibit operation of the EXP-INTF by holding the EI circuit pack in a reset state. This condition may result in an unsuccessful reset of the EI circuit pack.

If the reset command returns "PN is unavailable," perform the following steps:

1. Enter `change circuit-pack P`, where *P* is the Port Network number.
2. For the EI circuit pack you wish to reset, add an entry to the Circuit Pack screen for the TN570 EI circuit pack. Be sure to enter the appropriate carrier and slot.
3. Submit the screen.
4. Enter `busyout board location`
5. Enter `reset board location`

This test runs on [EXP-INTF \(Expansion Interface Circuit Pack\)](#).

|---------------|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3             | FAIL        | <p>The reset over the optical fiber failed.</p> <ol style="list-style-type: none"> <li>1. Enter <b>test board location</b> on the PN neighbor EI circuit pack located on the opposite end of the fiber from this EI circuit pack. If Test #238 fails, follow the maintenance procedure associated with this test result. Then perform the reset again.</li> <li>2. If the EI circuit pack is in the PN, temporarily remove the PN's Maintenance circuit pack.</li> <li>3. Enter <b>reset board location</b>.</li> <li>4. Reinsert the PN's Maintenance circuit pack if it was removed.</li> <li>5. If the symptoms match those described in the <a href="#">EI and Tone-Clock Interactions</a> section, follow those guidelines.</li> <li>6. Check the Error Log for the PN Tone-Clock errors that were resolved when the PN went down. These errors may have been resolved BECAUSE the PN went down. When there is no Tone-Clock generating the system clock on a PN, then an EI circuit pack can only be reset once. Every subsequent reset attempt fails. It is also possible that the system itself may have already tried to reset the EI circuit pack. Refer to <a href="#">TONE-BD (Tone-Clock Circuit Pack)</a> for Tone-Clock problems.</li> <li>7. If the reset still fails, run the <a href="#">Expansion Interface Manual Loopback Procedure</a> on the opposite PN EI circuit pack. This procedure is described in the section preceding the Error log entries and recommended actions table for this MO. If the EI circuit pack and the lightwave transceiver are healthy, the problem is the EI circuit pack and its lightwave transceiver on the PN end of the fiber or the fiber itself. Test the PN EI circuit pack with the manual loopback procedure and investigate the test results.</li> </ol> |
|               | PASS        | The EI was successfully reset. Release the EI circuit pack from the busyout state by using <b>release board location</b> .                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

## PN Maintenance Circuit Pack Serial Link Test (#337)

**This test is destructive.**

This test checks the serial link from the standby EI or standby IPSI circuit pack to the PN's Maintenance circuit pack. If there is no standby link or the standby link is down at the time of the test, this test aborts.

**Note:**

The status of the link changes to “down” when the standby EI or standby IPSI circuit pack begins initialization tests (for example, after being reset). The link status updates at the conclusion of these tests.

This test runs on [MAINT \(PN Maintenance Circuit Pack\)](#).

## Synchronization Update Test (#417)

This test updates all synchronization parameters for BRI, EI, DS1, ATM Trunk, and Tone/Clock circuit packs in the system. This test is run for the following maintenance objects:

- 1 [ATM-SYNC \(ATM Synchronization\)](#)

1 [SYNC \(Port Network Synchronization\)](#)

**Table 396: Synchronization Update Test (#417)**

## Digital Port Sanity Test (#565)

The Digital Port Sanity Test verifies that the port circuitry involved in the digital trunk testing on the Maintenance/Test digital port is functioning properly. This circuitry is common to both Maintenance/Test digital ports on the Maintenance/Test circuit pack and is only run for port 2. The test aborts if it is run on port 3.

The test connects the two Maintenance/Test digital ports on the TDM bus so that they talk and listen to each other. Four self-tests are attempted:

- 1 sending data from port 2 to port 3 in asynchronous mode
- 1 sending data from port 3 to port 2 in asynchronous mode
- 1 sending data from port 2 to port 3 in synchronous mode
- 1 sending data from port 3 to port 2 in synchronous mode

The test passes if all four self-tests are successful. The test stops if any one of the self-tests fails.

This test aborts if an ISDN test call is in progress on the Maintenance/Test digital port when the test is requested, or if an ISDN test call is initiated while the test is in progress.

This test runs on [M/T-DIG \(Maintenance/Test Digital Port\)](#).

## Hook State Inquiry Test (#566)

This test verifies that the Maintenance/Test analog port and the system agree on the on-hook/off-hook status of the Maintenance/Test analog port. It runs on [M/T-ANL \(Maintenance/Test Analog Port\)](#) and [M/T-DIG \(Maintenance/Test Digital Port\)](#).

## Packet Bus Port Health Inquiry Test (#567)

This test verifies that the packet bus fault-detection and maintenance function of the M/T-PKT is functioning properly. This is done by having the M/T-PKT perform a self-test. If the self-test passes, then the Packet Bus Port Health Inquiry test passes. If the self-test fails or Communication Manager cannot communicate with the M/T-PKT, then the test fails.

This test runs on [M/T-PKT \(Maintenance/Test Packet Bus Port\)](#).

---

## Maintenance/Test Circuit Pack Query Test (#572)

This test queries the Maintenance/Test packet bus port about the state of health of the packet bus. If the packet bus has faults, the test fails. The failure code describes the severity, type, and number of faults. The test passes if the packet bus is fault-free.

This test is run on [PKT-BUS \(Packet Bus\)](#).

**Note:**

A Maintenance/Test circuit pack is usually absent from the port networks of a standard-, duplex-, or high-reliability system. However, customers may optionally install a Maintenance/Test circuit pack to both utilize its enhanced analog-trunk and digital-line testing capabilities and to enhance the system's ability to quickly recognize a packet bus failure.

## Packet Circuit Pack Audit Test (#573)

This test determines whether Packet circuit packs have reported Packet Bus-related inline errors within the last minute. If so, the failure code indicates whether one or more than one circuit pack has reported such failures.

If the test has failed within the last 5 minutes, there is a 15 second delay before the result is returned. This prevents a repeated sequence of this test from always reporting the same result. If the test passes and a FAIL has not occurred within the last five minutes, a PASS is returned immediately.

This test is run on [PKT-BUS \(Packet Bus\)](#).

| 2          | FAIL        | More than one Packet circuit pack has reported packet bus-related inline errors within the last minute.                                                                                                                                                                                                                                                                                                                                                                               |
|            | PASS        | No Packet circuit packs have reported packet bus-related inline errors within the last minute. This indicates that the packet bus is healthy, or that a packet bus fault is transient or is being caused by a faulty Packet circuit pack. If this test passes, but there are other signs of a packet bus failure such as logged errors or alarms or other test failures, see <a href="#">Isolating and repairing packet-bus faults</a> in <i>Maintenance Procedures (03-300432)</i> . |

---

## Board Type Check Test (#574)

This test verifies that a Tone-Clock circuit pack administered with a Stratum-3 clock source has board code TN780.

This test runs on the following maintenance objects:

- 1 [TDM-CLK \(TDM Bus Clock\)](#)
- 1 [TONE-BD \(Tone-Clock Circuit Pack\)](#)
- 1 [TONE-PT \(Tone Generator\)](#)

**Table 402: Board Type Check Test (#574)**

| Error Code | Test Result | Description / Recommendation                                                                                                                                                                                                                                                                                                                              |

|            | PASS        | The proper Tone-Clock circuit pack is present for Stratum-3 clock synchronization.                                                                                                                                                                                                                                                                        |

## Expansion Interface Packet Interface Test (#589)

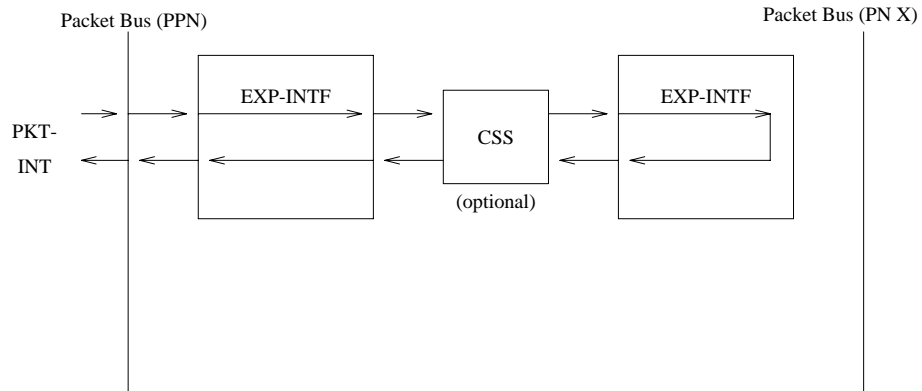

This test attempts to send a data packet from the TN1655 Packet Interface circuit pack through any intervening EI circuit packs and/or SNI circuit packs and through the EI circuit pack to be tested. The path the data packet takes is dependent on the location of the EI circuit pack to be tested and whether the system has duplicated PNC. The following diagrams and short discussion of each describe the different paths the test uses.

**Figure 102: Expansion Interface Packet Interface Test—Packet Endpoint Loop**

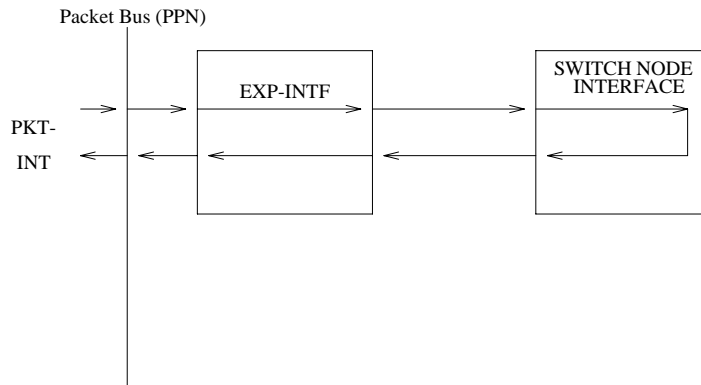

The path shown in [Figure 102: Expansion Interface Packet Interface Test—Packet Endpoint Loop](#) is used when testing a PN EI that is on the active PNC.

**Figure 103: Expansion Interface Packet Interface Test, PN-to-PN loop**

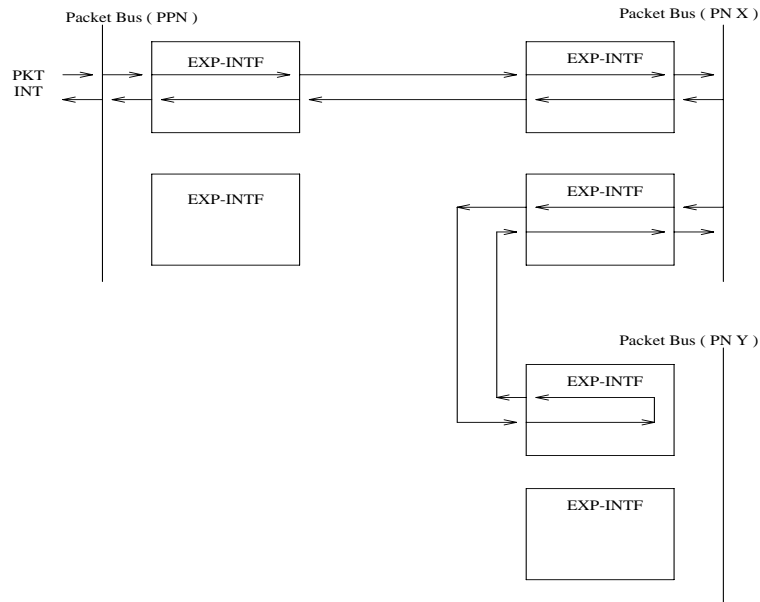

In a Center Stage configuration the path shown in [Figure 103: Expansion Interface Packet Interface Test, PN-to-PN loop](#) is used when testing a PN EI that is on the standby PNC. In a Direct Connect configuration, this path is used on any PN EI or on a PN EI that is on the standby PNC.

**Figure 104: Expansion Interface Packet Interface Test—PN to CSS Loop**

The path shown in [Figure 104: Expansion Interface Packet Interface Test—PN to CSS Loop](#) is used when running the test on a PN EI in a Center Stage configuration.

**Figure 105: Expansion Interface Packet Interface Test, PN-to-PN link**

The path shown in [Figure 105: Expansion Interface Packet Interface Test, PN-to-PN link](#) is used when the EI under test is one that provides connectivity between the two PNs in a Direct Connect configuration.

This test runs on [EXP-INTF \(Expansion Interface Circuit Pack\)](#).

Table 403: Expansion Interface Packet Interface Test (#589) 1 of 5

| Error Code | Test Result | Description / Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|------------|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1033       | ABORT       | <p>The test cot run because the EI circuit pack does not have a fiber link administered to it, there is not sufficient data to run the test, or because EI circuit packs on other port networks needed for this test are out of service.</p> <ol style="list-style-type: none"> <li>1. Enter <code>list fiber-link</code> and determine whether the EI circuit pack under test is an endpoint of one of the administered fiber links. If so, then proceed to step 2. If not, then this is considered to be a spare board, and the test should not be attempted on this EI circuit pack.</li> <li>2. Follow procedures for applicable configuration:</li> </ol> <p><b>Direct Connect:</b></p> <ol style="list-style-type: none"> <li>1. Enter <code>list config</code> for the cabinet and carrier where the neighbor EI circuit pack resides. If the results reveal that the board is not recognized by software, the board is out of service because of this condition. Perform the following steps: <ol style="list-style-type: none"> <li>a. If this test is being executed on an EI circuit pack located in the PN, enter <code>display errors</code> and resolve any EXP-PN errors for the port network where the neighbor EI circuit pack resides. Re-run this test.</li> <li>b. If this test continues to abort with Error Code 1033, reset the DS1 converter circuit pack, if so equipped, or the neighbor EI circuit pack. This will not be destructive since the circuit pack cot be serving as the Expansion Archangel if it is not in service.</li> </ol> </li> <li>2. Run Test #237 and check for EXP-INTF circuit pack Error Type 1281 in the Error Log. If Error Type 1281 is present and/or Test #237 does not pass, see repair procedures for <a href="#">Expansion Interface Neighbor Query Test (#237)</a>.</li> <li>3. If Test #237 passes, reseal the EI circuit pack. This will not be destructive since the circuit pack cot be serving as the Expansion Archangel if it is not in service.</li> <li>4. Rerun Test #237.</li> </ol> |

**Table 403: Expansion Interface Packet Interface Test (#589) 2 of 5**

| Error Code       | Test Result       | Description / Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
|------------------|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1033<br>(cont'd) | ABORT<br>(cont'd) | <p><b>Center Stage:</b><br/>                     If the EI circuit pack under test resides in the PN:<br/>                     None of the EI circuit packs located in the PNs (on the same PNC side) are in service (for PN EIs see the next case).</p> <ol style="list-style-type: none"> <li>5. Enter <code>list fiber-linklist fiber-link</code> to determine whether any of the PN's EI circuit packs are administered as endpoints of a fiber link. If not, then ignore the results of this test.</li> <li>6. Enter <code>list conf</code> for the cabinets and carriers where the EI circuit packs reside in every other PN. If the results returned indicated that the circuit packs are not recognized by software, they are out of service for this reason.</li> <li>7. Enter <code>display errors</code>, and resolve any <a href="#">EXP-PN (Expansion Port Network)</a> errors. Re-run this test.</li> <li>8. If the test continues to abort with this error code, reseal the EI circuit packs (or DS1 converter circuit pack if so equipped) on the PNs. This will not be destructive since the circuit pack cot be serving as the Expansion Archangel if it is not in service.</li> <li>9. Run Test #237 on each of the PN EI circuit packs, and check for EXP-INTF circuit pack Error Type 1281 in the error log. If Error Type is present and/or Test #237 does not pass, see repair procedures for <a href="#">Expansion Interface Neighbor Query Test (#237)</a>.</li> <li>10. Repeat this test.</li> </ol> <p><i>If the EI circuit pack under test resides in the PN:</i><br/>                     The EI circuit located in the PN is out of service.</p> <ol style="list-style-type: none"> <li>1. Run Test #237 on each of the PN EI circuit packs and check for EXP-INTF circuit pack Error Type 1281 in the error log. If Error Type is present and/or Test #237 does not pass, see repair procedures for <a href="#">Expansion Interface Neighbor Query Test (#237)</a>.</li> <li>2. Repeat this test.</li> </ol> |
| 1139             | ABORT             | <p>The packet bus in the PN where this EI circuit pack resides has a major alarm against it. This test needs to use the alarmed port network's packet bus.</p> <ol style="list-style-type: none"> <li>1. Enter <code>display alarms</code> and resolve any PKT-BUS alarms.</li> <li>2. Retry the command.</li> </ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

## Circuit Pack Restart Test (#594)

This test is destructive.

Run this test to reset the circuit pack only if there are PPCPU errors. This test fails if the circuit pack does not return to a sane state after being reset. The circuit pack resets through the SAKI Sanity test (#53).

This test runs on [VAL-BD \(Voice announcements over LAN Circuit Pack\)](#).

## LANBIC Receive Parity Error Counter Test (#595)

This test reads and clears the LANBIC Receive Parity Error Counter on the circuit pack. This counter is incremented by the circuit pack when it detects a parity error in data received from the packet bus.

These errors may indicate a circuit pack problem, packet bus problem, or a problem with another circuit pack on the bus. This test is useful for verifying the repair of the problem.

This test runs on the following maintenance objects:

- 1 [BRI-BD \(ISDN-BRI Line Circuit Pack\)](#)
- 1 [CLAN-BD \(Control LAN Circuit Pack\)](#)
- 1 [MG-BRI \(BRI Trunk Media Module\)](#)
- 1 [TBRI-BD \(ISDN Trunk-Side BRI Circuit Pack\)](#)
- 1 [VAL-BD \(Voice announcements over LAN Circuit Pack\)](#)

## Receive FIFO Overflow Error Counter Test (#596)

When the TN799 C-LAN or TN2501 VAL circuit pack detects packet bus buffer overflow, it increments the error on its FIFO Overflow error counter. This test reads and clears the counter.

This test runs on [CLAN-BD \(Control LAN Circuit Pack\)](#) and [VAL-BD \(Voice announcements over LAN Circuit Pack\)](#).

## Invalid LAPD Frame Error Counter Test (#597)

A TN799 C-LAN or TN2501 VAL circuit pack detects an invalid frame when it receives:

- 1 a frame with a CRC error
- 1 an unrecognizable frame
- 1 a recognizable frame in an unexpected state

When the circuit pack detects an Invalid LAPD Frame, it increments its Invalid LAPD Frame error counter. This test reads and clears the counter, and verifies the repair of the problem.

Errors may indicate a:

- 1 circuit pack problem
- 1 packet bus problem
- 1 problem with another circuit pack on the bus

This test runs on [CLAN-BD \(Control LAN Circuit Pack\)](#) and [VAL-BD \(Voice announcements over LAN Circuit Pack\)](#).

## Packet Interface Test (#598)

This test checks the circuit pack's packet bus interface. Data is sent through the bus and back to itself. If the data received is consistent with the data sent, the test passes. The test does not run if the specified PN's packet bus has a minor alarm or is out of service.

This test runs on the following maintenance objects:

- | [ATM-EI \(Expansion Interface Circuit Pack\)](#),
- | [ATM-TRK \(Circuit Emulation Service Circuit Pack\)](#)
- | [CLAN-BD \(Control LAN Circuit Pack\)](#)
- | [VAL-BD \(Voice announcements over LAN Circuit Pack\)](#)

## Congestion Query Test (#600)

The test queries the number of used buffers to determine whether a TN799 [CLAN-BD \(Control LAN Circuit Pack\)](#) or [VAL-BD \(Voice announcements over LAN Circuit Pack\)](#) is congested.

If the test fails on a TN799 C-LAN circuit pack, the switch redirects outgoing calls to another available C-LAN and denies new incoming calls.

If the test fails on a TN2501 VAL circuit pack, the switch alarms and announcements can fail. Normal call handling resumes when the C-LAN or VAL circuit pack recovers from congestion.

**Table 409: Congestion Query Test (#600) 1 of 2**

## Link Status Test (#601)

This test determines the state of the call-control signaling link for the TN799 [CLAN-BD \(Control LAN Circuit Pack\)](#) and [VAL-BD \(Voice announcements over LAN Circuit Pack\)](#). If the signaling link is physically connected, the test sends a test frame over the link and checks for a response. The test passes only if both the signaling link is connected and the test frame is successfully transmitted.

A failure may indicate a problem with:

- 1 this circuit pack
- 1 the packet bus
- 1 the Packet Interface circuit pack

## TSC Heartbeat Inquiry Test (#604)

This test can be invoked for any ADM TSC administered in the switch. Most of the error conditions in the following table will not log an error, but switched services may take some type of recovery action in certain instances.

This test sends a USER INFORMATION TSC heartbeat message inquiry across an ADM TSC. It passes if the far end sends a response. It fails if there is no response.

This test runs on [TSC-ADM \(Administered Temporary Signaling Connections\)](#)

## BRI NPE Crosstalk Test (#617)

**This test is destructive.**

One or more Network Processor Elements (NPEs) reside on each circuit pack with a TDM-bus interface. The NPE controls port connectivity and gain, and provides conferencing functions on a per-port basis. The BRI NPE Crosstalk test verifies that the port's NPE channel talks on the selected time slot and never crosses over to time slots reserved for other connections. If the NPE is not working correctly, one-way and noisy connections may be observed. This test is part of a port's long test sequence and executes in approximately 20 to 30 seconds. Crosstalk testing is performed on both B-Channels (B1 and B2) associated with a BRI port. If this test fails on either channel, any endpoint connected to the port is taken out-of-service. This test aborts if the port and its associated channels are not in the idle state.

This test runs on [BRI-PORT \(ISDN-BRI Port\)](#) and [TBRI-PT \(ISDN Trunk-Side BRI Port\)](#).

## BRI Port Local LAN Looparound Test (#618)

### This test is destructive.

This test checks the connectivity of a BRI port across the LAN Bus and executes only if the port is out-of-service. The test aborts if calls associated with the port are in-progress. Failures of this test indicate either on-board faults associated with the port hardware on the circuit pack or problems with the LAN Bus.

This test runs on the following maintenance objects:

- 1 [ASAI-PT \(ASAI Port\)](#)
- 1 [BRI-PORT \(ISDN-BRI Port\)](#)
- 1 [TBRI-PT \(ISDN Trunk-Side BRI Port\)](#)

## BRI Port Local TDM Looparound Test (#619)

### This test is destructive.

This test verifies the connectivity of a BRI port across the TDM Bus. It aborts if calls associated with the port are in progress. Failure of this test indicates an on-board fault associated with the port hardware on the circuit pack.

This looparound test runs the following individual tests on the two B-channels (B1 and B2) associated with the port:

- 1 Looparound test across the TDM Bus for B1.
- 1 Conference Circuit test for B1.
- 1 Looparound test across the TDM Bus for B2.
- 1 Conference Circuit test for B2.

The tests are run in the above order. If one test fails, the remaining tests in the sequence are not executed and an error code is returned at that point.

This test runs on [BRI-PORT \(ISDN-BRI Port\)](#) and [TBRI-PT \(ISDN Trunk-Side BRI Port\)](#).

## Electronic Power Feed Restoral Test (#620)

This test attempts to restore the Electronic Power Feed (EPF) on an ISDN-BRI port twice. In this test, the processor requests that the EPF be turned on for a given port. An attempt is made to turn on the power unit to the station or adjunct. If no current is being drawn by a station, this probably indicates that the station is not connected. No current being drawn by an adjunct is the normal condition. If an overcurrent condition is sensed (that is, too much current is being drawn), this condition may indicate a short in the wiring to the endpoint or adjunct. Depending on what condition is sensed, a message is returned stating that either the EPF was turned on successfully with no problems or that an overcurrent condition is sensed. This response is reported by the Electronic Power Feed Inquiry (#622), which follows in the testing sequence. EPF Restoral is attempted again by this test five seconds later. This test always passes for the TN2198 because it has no EPF. This test will always abort when run on the TN2208.

This test runs on [BRI-PORT \(ISDN-BRI Port\)](#).

**Table 415: Electronic Power Feed Restoral Test (#620)**

| Error Code | Test Result | Description / Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

## Level 1 Status Inquiry Test (#621)

This test determines the state of the transmission facility of a BRI port at the physical layer (Level 1). Level 1 can be in one of three possible states: Activated, Pending Activation, or Deactivated.

The Activated state is the correct state for an ISDN-BRI port. In this state, the Level 1 interface can communicate with the BRI endpoint or ASAI or Avaya adjunct administered on this port. This test passes if the state of Level 1 (L1) is Activated. This test also passes if software has taken this port out of service. See the description of the Level 1 "Deactivated State" below for more details.

The Pending Activation state indicates a problem with the endpoints or adjunct, the wiring to the sets or adjunct, or the BRI-LINE or circuit pack. When in this state, the Level 1 interface is either not receiving any L1 framing from the endpoint or adjunct (Endpoint Idle), or it is communicating with the endpoint or adjunct but not transition to the Activated state (Endpoint Active).

The Deactivated state indicates a problem with the BRI-LINE circuit pack. When in this state, the Level 1 interface is idle and is not trying to communicate with the BRI endpoints or adjunct. When an ISDN-BRI port is placed in the out-of-service state, Level 1 is also put into the Deactivated state. This could be due either to the system detecting a fault with the port or a `busyout port location` request.

This test runs on [ASAI-PT \(ASAI Port\)](#) and [BRI-PORT \(ISDN-BRI Port\)](#).

## Electronic Power Feed Inquiry Test (#622)

This test queries the BRI-LINE circuit pack for the status of the Electronic Power Feed (EPF) supplied to a BRI endpoint or an ASAI or Avaya adjunct. If the EPF is on and no overcurrent condition exists, this test passes. All other states are not normal and indicate a problem with the endpoint or adjunct, the wiring to the endpoint or adjunct, or the BRI-LINE circuit pack. This test is not run on the TN2208 circuit pack or the TN2198 and will always return a pass for the TN2198. The TN2208 has no power feeds

This test runs on [BRI-PORT \(ISDN-BRI Port\)](#).

Table 417: Electronic Power Feed Inquiry Test (#622) 1 of 2

| Error Code    | Test Result | Description / Recommendation                                                                                                                                           |
|---------------|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1005          | ABORT       | This test is not valid for this port type. Ports on the TN2208 cot run this test because this board does not have an electronic power feed. This error can be ignored. |

## CRC Error Counter Test (#623)

This test reads the port's CRC error counters that are maintained on the circuit pack. The Cyclic Redundancy Check (CRC) is a means of error detection to determine the integrity of data frame contents. The CRC error counter is incremented by the circuit pack when it detects a CRC error. The test passes if the value of the counter is 0, meaning the error is cleared. If the counter is non-zero, the test fails and the value of the counter is displayed in the `Error Code` field.

This test runs on [ASAI-PT \(ASAI Port\)](#), [BRI-PORT \(ISDN-BRI Port\)](#), and [TBRI-PT \(ISDN Trunk-Side BRI Port\)](#).

Table 418: CRC Error Counter Test (#623)

| Error Code   | Test Result | Description / Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

## Layer 1 Transmission Error Counter Test (#624)

This test reads and clears the port's Layer 1 Transmission error counter maintained on the ASAI or BRI-LINE circuit pack. This counter is incremented by the circuit pack when it detects a Layer 1 transmission problem. The test passes if the value of the counter is 0 (that is, the error is cleared). If the counter is not zero, the test fails, and the value of the counter is displayed in the Error Code field.

This error is most likely due to a problem with the wiring or the endpoint or adjunct. Verify that the wiring meets the configuration rules defined in *DEFINITY® Communications System Generic 1 and Generic 3i Wiring*. It does not indicate a problem with the circuit pack. This test is useful for verifying the repair of the problem.

This test runs on [ASAI-PT \(ASAI Port\)](#) and [BRI-PORT \(ISDN-BRI Port\)](#).

## Receive FIFO Error Counter Test (#625)

This test reads and clears the port's Receive FIFO error counter maintained on the circuit pack. This counter is incremented by the circuit pack when it detects an overflow of its receive buffers. The test passes if the value of the counter is 0 (that is, the error is cleared). If the counter is not zero, the test fails, and the value of the counter is displayed in the Error Code field.

This error can occur if signaling frames are being received from a packet bus at a rate sufficient to overflow the receive buffers on the circuit pack for a port or if a hardware fault is causing the receive buffers not to be emptied properly. This test is useful for verifying the repair of the problem. This test runs on the following maintenance objects:

- 1 [ASAI-PT \(ASAI Port\)](#)
- 1 [BRI-PORT \(ISDN-BRI Port\)](#)
- 1 [TBRI-PT \(ISDN Trunk-Side BRI Port\)](#)

## Signaling Link Status Test (#626)

This test determines the current status of the signaling link. This test passes if the link is “bound” to an endpoint and fails if the link is “not bound.”

The definition of the term “bound” for a link depends upon the type of endpoint and may depend on the successful completion of procedures at both Layers 2 and 3 of the protocol. The definition of “bound” for each type of endpoint is as follows:

- 1 BRI endpoints administered for MIM (management information messages) initialization (multipoint):

## Maintenance Demand Tests

### Note:

An MIM is a level 3 message that conveys management and maintenance information between a communications system and a BRI terminal.

For endpoints of this type, the signaling link is “bound” when the link is connected at Layer 2 and the link has been associated with an endpoint, [that is, the endpoint has completed SPID initialization (L3 established)].

- 1 ASAI adjuncts and BRI endpoints not administered for MIM initialization (point-to-point):

For endpoints of this type, the signaling link is “bound” when the link is connected at Layer 2 (L2 established).

For every endpoint type, a signaling link becomes “unbound” when it is disconnected at Layer 2. For BRI endpoints supporting MIM initialization, a signaling link may also become “unbound” if a subsequent attempt to perform SPID initialization on a “bound” link fails (that is, wrong SPID is entered into the endpoint by the user).

This test runs on [ASAI-EPT \(ASAI Endpoint\)](#) and [BRI-SET, Various Adjuncts](#).

## BRI Remote Loopback Test (#627)

This test checks the integrity of a circuit-switched B-channel connection between the switch and the endpoint.

The endpoint is put in the “maintenance busy” state to prevent the switch from entering calls to the endpoint during the test. An application message containing a loopback activate request for the appropriate B-channel is sent to the endpoint. The endpoint responds with a loopback activated response. The switch then sends data to the endpoint over the B-channel under test. Since the B-channel is looped back at the endpoint, maintenance should receive the data that it sent. If no data is detected, the test fails. The switch then releases the endpoint so that it is available to terminate calls.

This test is not executed for ASAI adjuncts because adjuncts do not support MIMs upon which this test is based. This test is run on [BRI-SET, Various Adjuncts](#).
