

**Maintenance Alarms for Avaya
Aura™ Communication Manager,
Media Gateways and Servers**

03-300430
Issue 6
August 2010

Notice

While reasonable efforts have been made to ensure that the information in this document is complete and accurate at the time of printing, Avaya assumes no liability for any errors. Avaya reserves the right to make changes and corrections to the information in this document without the obligation to notify any person or organization of such changes.

Documentation disclaimer

Avaya shall not be responsible for any modifications, additions, or deletions to the original published version of this documentation unless such modifications, additions, or deletions were performed by Avaya.

End User agree to indemnify and hold harmless Avaya, Avaya's agents, servants and employees against all claims, lawsuits, demands and judgments arising out of, or in connection with, subsequent modifications, additions or deletions to this documentation, to the extent made by End User.

Link disclaimer

Avaya is not responsible for the contents or reliability of any linked Websites referenced within this site or documentation(s) provided by Avaya. Avaya is not responsible for the accuracy of any information, statement or content provided on these sites and does not necessarily endorse the products, services, or information described or offered within them. Avaya does not guarantee that these links will work all the time and has no control over the availability of the linked pages.

Warranty

Avaya provides a limited warranty on this product. Refer to your sales agreement to establish the terms of the limited warranty. In addition, Avaya's standard warranty language, as well as information regarding support for this product, while under warranty, is available to Avaya customers and other parties through the Avaya Support Website: <http://www.avaya.com/support>. Please note that if you acquired the product from an authorized Avaya reseller outside of the United States and Canada, the warranty is provided to you by the said Avaya reseller and not by Avaya.

Licenses

The software license terms available on the Avaya Website, <http://support.avaya.com/licenseinfo/> are applicable to anyone who downloads, uses and/or installs Avaya software, purchased from Avaya Inc., any Avaya affiliate, or an authorized Avaya reseller (as applicable) under a commercial agreement with Avaya or an authorized Avaya reseller. Unless otherwise agreed to by Avaya in writing, Avaya does not extend this license if the software was obtained from anyone other than Avaya, an Avaya affiliate or an Avaya authorized reseller, and Avaya reserves the right to take legal action against you and anyone else using or selling the software without a license. By installing, downloading or using the software, or authorizing others to do so, you, on behalf of yourself and the entity for whom you are installing, downloading or using the software (hereinafter referred to interchangeably as "you" and "end user"), agree to these terms and conditions and create a binding contract between you and Avaya Inc. Or the applicable Avaya affiliate ("Avaya").

Avaya grants End User a license within the scope of the license types described below. The applicable number of licenses and units of capacity for which the license is granted will be one (1), unless a different number of licenses or units of capacity is specified in the Documentation or other materials available to End User. "Designated Processor" means a single stand-alone computing device. "Server" means a Designated Processor that hosts a software application to be accessed by multiple users. "Software" means the computer programs in object code, originally licensed by Avaya and ultimately utilized by End User, whether as stand-alone products or pre-installed on Hardware. "Hardware" means the standard hardware originally sold by Avaya and ultimately utilized by End User.

License types

- Designated System(s) License (DS):
End User may install and use each copy of the Software on only one Designated Processor, unless a different number of Designated Processors is indicated in the Documentation or other materials available to End User. Avaya may require the Designated Processor(s) to be identified by type, serial number, feature key, location or other specific designation, or to be provided by End User to Avaya through electronic means established by Avaya specifically for this purpose.
- Concurrent User License (CU):
End User may install and use the Software on multiple Designated Processors or one or more Servers, so long as only the licensed number of Units are accessing and using the Software at any given time. A "Unit" means the unit on which Avaya, at its sole discretion, bases the pricing of its licenses and can be, without limitation, an agent, port or user, an e-mail or voice mail account in the name of a person or corporate function (e.g., webmaster or helpdesk), or a directory entry in the administrative database utilized by the

Software that permits one user to interface with the Software. Units may be linked to a specific, identified Server.

- Named User License (NU):
End User may: (i) install and use the Software on a single Designated Processor or Server per authorized Named User (defined below); or (ii) install and use the Software on a Server so long as only authorized Named Users access and use the Software. "Named User" means a user or device that has been expressly authorized by Avaya to access and use the Software. At Avaya's sole discretion, a "Named User" may be, without limitation, designated by name, corporate function (for example, webmaster or helpdesk), an e-mail or voice mail account in the name of a person or corporate function, or a directory entry in the administrative database utilized by the Software that permits one user to interface with the Software.
- Shrinkwrap License (SR):
Customer may install and use the Software in accordance with the terms and conditions of the applicable license agreements, such as "shrinkwrap" or "clickthrough" license accompanying or applicable to the Software ("Shrinkwrap License"). (See Third-party Components for more information).

Copyright

Except where expressly stated otherwise, no use should be made of materials on this site, the Documentation(s) and Product(s) provided by Avaya. All content on this site, the documentation(s) and the product(s) provided by Avaya including the selection, arrangement and design of the content is owned either by Avaya or its licensors and is protected by copyright and other intellectual property laws including the sui generis rights relating to the protection of databases. You may not modify, copy, reproduce, republish, upload, post, transmit or distribute in any way any content, in whole or in part, including any code and software. Unauthorized reproduction, transmission, dissemination, storage, and or use without the express written consent of Avaya can be a criminal, as well as a civil, offense under the applicable law.

Third Party Components

Certain software programs or portions thereof included in the Product may contain software distributed under third party agreements ("Third Party Components"), which may contain terms that expand or limit rights to use certain portions of the Product ("Third Party Terms"). Information regarding distributed Linux OS source code (for those Products that have distributed the Linux OS source code), and identifying the copyright holders of the Third Party Components and the Third Party Terms that apply to them is available on the Avaya Support Website: <http://support.avaya.com/Copyright>.

Preventing toll fraud

"Toll fraud" is the unauthorized use of your telecommunications system by an unauthorized party (for example, a person who is not a corporate employee, agent, subcontractor, or is not working on your company's behalf). Be aware that there can be a risk of toll fraud associated with your system and that, if toll fraud occurs, it can result in substantial additional charges for your telecommunications services.

Avaya fraud intervention

If you suspect that you are being victimized by toll fraud and you need technical assistance or support, call Technical Service Center Toll Fraud Intervention Hotline at +1-800-643-2353 for the United States and Canada. For additional support telephone numbers, see the Avaya Support Website:

<http://www.support.avaya.com/>.

Suspected security vulnerabilities with Avaya products should be reported to Avaya by sending mail to: securityalerts@avaya.com.

Trademarks

Avaya® and Avaya Aura™ are trademarks of Avaya Inc.

The trademarks, logos and service marks ("Marks") displayed in this site, the documentation(s) and product(s) provided by Avaya are the registered or unregistered Marks of Avaya, its affiliates, or other third parties. Users are not permitted to use such Marks without prior written consent from Avaya or such third party which may own the Mark. Nothing contained in this site, the documentation(s) and product(s) should be construed as granting, by implication, estoppel, or otherwise, any license or right in and to the Marks without the express written permission of Avaya or the applicable third party. All non-Avaya trademarks are the property of their respective owners.

Downloading documents

For the most current versions of documentation, see the Avaya Support Website: <http://www.avaya.com/support>.

Contact Avaya Support

Avaya provides a telephone number for you to use to report problems or to ask questions about your product. The support telephone number is 1-800-242-2121 in the United States. For additional support telephone numbers, see the Avaya Website: <http://www.avaya.com/support>.

Introduction

This document provides procedures to monitor, test, and maintain an Avaya Server or Media Gateway system. It covers many of the faults and troubles that can occur and provides procedures to correct them.

Using this documentation, the Avaya technicians and the technicians of their business partners and customers should be able to follow detailed procedures for:

- 1 Monitoring, testing, and maintaining an Avaya Server, Media Gateway, and many other system components.
- 1 Using troubleshooting methods to clear faults.
- 1 Required replacements, visual inspections, continuity checks, and clarifying operating procedures with end users.

Document set

Although this maintenance book is published separately, it is part of a set:

- 1 *Maintenance Alarms for Avaya Aura™ Communication Manager, Media Gateways and Servers*, 03-300430 (formerly 03-300190, 555-245-102)
- 1 *Maintenance Commands for Avaya Aura™ Communication Manager, Media Gateways and Servers*, 03-300431 (formerly 03-300191, 555-245-101)
- 1 *Maintenance Procedures for Avaya Aura™ Communication Manager, Media Gateways and Servers*, 03-300432 (formerly 03-300192, 555-245-103)

Organization

The Server Alarms chapter has been moved to *Avaya Aura™ Communication Manager Server Alarms (03-602798)*

The Denial Events chapter has been moved to *Avaya Aura™ Communication Manager Denial Events (03-602793)*

The Media Gateway Traps chapter has been moved to *Gateway Traps for the G250/G350/G430/G450/G700 Avaya S8xxxx Servers (03-602803)*

The LEDs chapter has been moved to *LED Descriptions for Avaya Aura™ Communication Manager Hardware Components (03-602804)*

Introduction

[Chapter 1: Communication Manager Maintenance Object Repair Procedures](#), contains specific troubleshooting and repair instructions for every component in the system. The maintenance objects are listed alphabetically by name as they appear in the Alarm and Error Logs. Under each maintenance object appears a description of the object's function, tables for interpreting alarm and error logs, and instructions on how to use tests, commands, and replacements to resolve associated problems.

[Chapter 2: Maintenance Demand Tests](#) contains all of the demand tests that can be executed, the error codes returned, and the recommended actions for troubleshooting and repairing the problem.

Equipment/platforms

This book contains information regarding alarms on the following equipment/platforms

- 1 Avaya Media Servers
- 1 Avaya Media Gateways

Audience

The information in this book is intended for use by Avaya technicians, provisioning specialists, business partners, and customers, specifically:

- 1 Trained Avaya technicians
- 1 A maintenance technician dispatched to a customer site in response to a trouble alarm or a user trouble report
- 1 A maintenance technician located at a remote maintenance facility
- 1 The customer's assigned maintenance technician

The technician is expected to have a working knowledge of telecommunications fundamentals and of the particular Avaya Server and/or Media Gateway to the extent that the procedures in this book can be performed, in most cases, without assistance.

This book is not intended to solve all levels of troubles. It is limited to troubles that can be solved using:

- 1 The Alarm Log
- 1 The Error Log
- 1 Trouble-clearing procedures
- 1 Maintenance tests
- 1 Traditional troubleshooting methods

If the trouble still has not been resolved, it is the maintenance technician's responsibility to escalate the problem to a higher level of technical support. Escalation should conform to the procedures in the Technical and Administration Escalation Plan.

How to use this Document

Most maintenance sessions involve analyzing the Alarm and Error Logs to diagnose a trouble source and replacing a component such as a circuit pack or media module. The information in [Chapter 1: Communication Manager Maintenance Object Repair Procedures](#) of this reference will generally suffice to address these needs.

Certain complex elements of the system require a more comprehensive approach. Special procedures for these elements appear in [Chapter 4: General troubleshooting](#) of *Maintenance Procedures for Avaya Aura™ Communication Manager, Media Gateways and Servers (03-300432)*.

Structure of the book

This document includes new information developed for this release of Communication Manager. In order to present maintenance information from all these sources side-by-side, marking conventions delineate material specific to a particular source. The markers act on two levels:

- 1 [Major and minor sections](#)
- 1 [Paragraphs or inline comments](#)

Major and minor sections

At the Major and minor sections level, a ruled line delineates the beginning of a section of material specific to the server or gateway identified in bold. At the conclusion of the section, another ruled line marks the end of the specific material and a return to common text. For example, a section of material specific to the S8720 or S8500 server would look like:

S8700 | S8710 | S8720 | S8500

1. If only 1 analog circuit pack in the system has this problem, replace the circuit pack.
2. If only analog circuit packs on a particular carrier have this error, the ringing generator may not be connected to this carrier.
3. If analog circuit packs on many carriers have this error, it is probably a problem with the ringing generator.

Such sections can occasionally extend for several pages.

Paragraphs or inline comments

At the paragraph level and for inline comments, the specific server or gateway is indicated by its bold name, and the parenthetical information follows immediately afterward. For example, a paragraph insert for the S8710 and S8500 servers might look like:

1. If the Tone-Clock circuit is a slave clock, then the EI to which it is listening is providing a bad timing source. Follow the diagnostic procedures specified for TDM-CLK Error Code 2305.
2. **S8700 | S8710 | S8720 | S8500**: If no problem can be found with the incoming synchronization signal, replace the IPSI or Tone-Clock circuit pack. See [Replacing the IPSI or Tone-Clock Circuit Pack](#).

In such cases, it is not necessary to delineate the beginning and end of the material.

An example of an inline comment might look like:

3. **Error Type 1**: There is a serial number mismatch between the hardware serial number and installed license file (**S8700 | S8710 | S8720 | S8500**: there is a serial-number mismatch of the reference IPSI and a subsequent License Error failure. **S8300**: there is a serial-number mismatch of the Media Gateway motherboard on which the serial number resides and a subsequent License Error failure). This error is caused by the:
 1. **S8700 | S8710 | S8720 | S8500**: Reference IPSI not responding
S8300: Media Gateway motherboard not responding
 1. Expiration of the 10-day timer

The system enters No-License mode.

It is hoped that, by these techniques, material specific to several different sources can be combined and viewed side-by-side without confusion.

Conventions used in this document

[Table 1: Typography used in this book](#) describes the typographic conventions used in this document.

Table 1: Typography used in this book 1 of 2

To represent . . .	This typeface and syntax are shown as . . .	For example, . . .
SAT screen commands	<ul style="list-style-type: none"> Bold for literals Bold italic for <i>variables</i> Square brackets [] around optional parameters "Or" sign between exclusive choices 	refresh ip-route [all location]
SAT screen input and output	<ul style="list-style-type: none"> Bold for input Constant width for output (screen displays and messages) 	Set the Save Translation field to daily . The message Command successfully completed should appear.
Linux commands	<ul style="list-style-type: none"> Constant-width bold for literals Constant-width bold italics for <i>variables</i> Square brackets [] around optional arguments "Or" sign between exclusive choices 	testmodem [-s] [-t arg]
Linux output	Constant width	Linux returns the message almdisplay 4: Unable to connect to CommunicMgr.

Table 1: Typography used in this book 2 of 2

To represent . . .	This typeface and syntax are shown as . . .	For example, . . .
Web interface	<ul style="list-style-type: none"> Bold for menu selections, tabs, buttons, and field names Right arrow > to separate a sequence of menu selections 	<p>Select Alarms and Notification, the appropriate alarm, and then click Clear.</p> <p>Select Diagnostics > View System Logs, then click Watchdog Logs.</p>
Keys	Special font for keyboard keys and SAT screen clickable buttons	<p>Press Tab.</p> <p>Click Next Page.</p>
		2 of 2

Introduction

Other conventions used in this book:

- 1 Physical dimensions are in English [Foot Pound Second (FPS)] units, followed by metric [Centimeter Gram Second (CGS)] units in parentheses.

Wire-gauge measurements are in AWG, followed by the diameter in millimeters in parentheses.

- 1 Circuit-pack codes (such as TN790B or TN2182B) are shown with the minimum acceptable alphabetic suffix (like the “B” in the code TN2182B).

Generally, an alphabetic suffix higher than that shown is also acceptable. However, not every vintage of either the minimum suffix or a higher suffix code is necessarily acceptable.

Useful terms

[Table 2: Terminology summary](#) summarizes several of the terms used in this book and relates them to former terminologies.

Table 2: Terminology summary

Present Terminology	Former Terminology
Communication Manager	DEFINITY MultiVantage Avaya Call Processing
S8300 Server	ICC, Internal Call Controller
S8700-series Server (or non-co-resident S8300)	ECC, External Call Controller
MGP, Media Gateway Processor	860T Processor
Layer 2 Switching Processor	P330 Stack Processor Cajun Stack Processor i960 Processor
Fiber-PNC	Multiconnect. This is an umbrella term for direct-connect, CSS-connected, and ATM-connected PNC.
IP-PNC	IP-connect

Trademarks

All trademarks identified by the ® or ™ are registered trademarks or trademarks, respectively, of Avaya Inc. All other trademarks are the property of their respective owners.

Safety labels and security alert labels

Observe all caution, warning, and danger statements to help prevent loss of service, equipment damage, personal injury, and security problems. This book uses the following safety labels and security alert labels:

 **CAUTION:**

A caution statement calls attention to a situation that can result in harm to software, loss of data, or an interruption in service.

A warning statement calls attention to a situation that can result in harm to hardware or equipment.

 **DANGER:**

A danger statement calls attention to a situation that can result in harm to personnel.

 **SECURITY ALERT:**

A security alert calls attention to a situation that can increase the potential for unauthorized use of a telecommunications system.

Safety precautions

When performing maintenance or translation procedures on the system, observe all caution, warning, and danger admonishments to prevent loss of service, possible equipment damage, and possible personal injury. In addition, the following precautions regarding electromagnetic interference (EMI) and static electricity must be observed:

Electromagnetic interference

This equipment generates, uses, and can radiate radio frequency energy. Electromagnetic fields radiating from the switch may cause noise in the customer's equipment. If the equipment is not installed and used in accordance with the instruction book, radio interference may result.

To maintain the EMI integrity of the system, maintenance personnel must ensure that all cabinet panels, covers, and so forth, are firmly secured before leaving the customer's premises.

Downloading this book and updates from the Web

The latest version of this book can be downloaded from the Avaya Web site. You must have access to the Internet, and a copy of Acrobat Reader must be installed on your personal computer.

Avaya makes every effort to ensure that the information in this book is complete and accurate. However, information can change after the book has been published. The Avaya Web site may contain new product information and updates to the information in this book.

To download the latest version of this book:

1. Access the Avaya Web site at <http://support.avaya.com>
2. Click on **Advanced Search** on the top right of the screen
3. Enter the name or number of the document

Technical assistance

Avaya provides the following resources for technical assistance.

Within the United States

For help with:

- 1 Feature administration and system applications, call Avaya Technical Consulting Support at 1-800-225-7585
- 1 Maintenance and repair, call the Avaya National Customer Care Support Line at 1-800-242-2121
- 1 Toll fraud, call Avaya Toll Fraud Intervention at 1-800-643-2353

International

For all international resources, contact your local Avaya authorized dealer for additional help.

Chapter 1: Communication Manager Maintenance Object Repair Procedures

This chapter provides information for troubleshooting and repairing maintenance objects.

Note:

This chapter does not contain maintenance objects for the Avaya Wireless Business System or messaging systems. Refer to the documentation that accompanies these products for this information.

Each identifiable part in the system is considered a maintenance object (MO). A maintenance object can be:

- 1 An individual circuit pack or media module
- 1 A hardware component that is part of a circuit pack or media module
- 1 Any software process
- 1 Significant events
- 1 Environmental controls
- 1 A cabinet

Each maintenance object has its own unique set of tests, error codes, and recovery strategy. Maintenance software logs inline errors reported by circuit packs and media modules, runs tests for error diagnosis and recovery, and raises and clears alarms.

“Maintenance names” are recorded in the Error and Alarm logs. Individual copies of an MO are assigned an address that defines the MO’s physical location in the system when applicable. These locations display as the **port** field in the Alarm and Error logs and as output of commands such as `test board` (see [Figure 1: Display of test board](#)).

Figure 1: Display of test board

```
test board lv4 long                                     Page 1
```

TEST RESULTS

Port	Maintenance Name	Alt. Name	Test No.	Result	Error Code
001V4	MG-DS1		50	ABORT	1412
001V4	MG-DS1		52	PASS	
001V4	MG-DS1		138	PASS	
001V4	MG-DS1		139	PASS	
001V4	MG-DS1		140	PASS	
001V4	MG-DS1		141	PASS	
001V4	MG-DS1		142	PASS	
001V4	MG-DS1		143	PASS	
001V4	MG-DS1		144	PASS	
001V4	MG-DS1		145	PASS	
001V4	MG-DS1		146	PASS	
001V4	MG-DS1		1227	ABORT	1412
001V401	TIE-DS1	0001/001	7	ABORT	1412

Displaying MOs Maintained by Communication Manager

Communication Manager maintenance objects are displayed using the `list configuration` or `show mg list_config` command.

`list config all` on the Communication Manager System Access Terminal (SAT) screen displays the Board Name (location), Board Type, Code, Vintage, and the assigned ports, if any, of all installed equipment in the system.

`show mg list_config` on the MGP displays information for the installed equipment in that media gateway.

Media Gateway Subsystems

The Media Gateway subsystems are either field replaceable or integrated (part of the system and not replaceable). These subsystems are not under Communication Manager control and are not maintained by the system. [Table 4: Media Gateway Subsystems Maintained by Communication Manager](#) lists the applicable subsystems and if they are field replaceable or not.

Table 4: Media Gateway Subsystems Maintained by Communication Manager

Subsystem	Field Replaceable
Any Media Module	Yes
VOIP Media Module	No
Announcement Circuitry (part of the MGP)	No

Media Gateway Maintenance Objects Maintained by Communication Manager

The maintenance strategy for the Media Gateways is intended to provide easy fault isolation procedures and to restrict problems to field-replaceable components. The following list contains the maintenance objects which are under Communication Manager control and are maintained by the system:

- 1 [MED-GTWY \(MEDIA GATEWAY\)](#)
- 1 [MG-ANA \(Analog Media Module\)](#)
- 1 [MG ANN \(Media Gateway Announcement Module\)](#)
- 1 [MG-BRI \(BRI Trunk Media Module\)](#)
- 1 [MG-DCP \(Digital Line Media Module\)](#)
- 1 [MG-DS1 \(DS1 Interface Media Module\)](#)
- 1 [MG-IAMM \(Integrated Analog Media Module\)](#)
- 1 [MG-VOIP \(MM760 VoIP Media Module\)](#)

MO groupings by Media Module type

[Table 5: Media Module Types](#) shows MO groupings by Media Module type.

Table 5: Media Module Types 1 of 2

Media Module (MM)	Maintenance Object (MO)
E1/T1 Media Module	Board (MG-DS1)
	DS1 CO Trunk (CO-DS1)
	DS1 DID Trunk (DID-DS1)
	DS1 Tie Trunk (TIE-DS1)
	DS1 ISDN Trunk (ISDN-TRK)
	ISDN-PRI Signaling Link Port (ISDN-PLK)
	ISDN-PRI Signaling Group (ISDN-SGRP)
	Wideband Access Endpoint Port (WAE-PORT)
Analog Media Module	Board (MG-ANA)
	Analog Line (AN-LN-PT)
	Analog Co Trunk (CO-TRK)
	Analog DID Trunk (DID-TRK)
	DIOD Trunk (DIOD-TRK)
	Alarm Port (ALARM-PT)
DCP Media Module	Board (MG-DCP)
	Digital Line (DIG-LINE)

1 of 2

Table 5: Media Module Types 2 of 2

Media Module (MM)	Maintenance Object (MO)

Viewing Communication Manager Alarms

Communication Manager alarms and events are viewed using commands that are available via the Web Interface or the SAT command-line interface (CLI). See [Table 6: Commands for Viewing Communication Manager Alarms](#).

Table 6: Commands for Viewing Communication Manager Alarms

Command	Interface	Purpose	Description
<code>View Current Alarms</code>	Web Interface, under Alarms and Notification	View a list of outstanding alarms against Communication Manager	Displays a summary of alarms, if present, followed by a detailed table of explanation.
<code>display alarms</code>	SAT CLI	View logged Communication Manager alarms	These are alarms that have not yet been cleared, either manually or via an Expert System.

Command Syntax

Commands use a different syntax for the board or port location depending upon whether they refer to circuit packs or media modules. Test command sequences can be either short or long (l). The default is short. The test sequence can be repeated several times. The default is 1.

Communication Manager Maintenance Object Repair Procedures

The following is an example for running a long test sequence twice on a port on a circuit pack:

```
test port UUCSSpp 1 r 2
```

- | *UU* = the universal cabinet number (1 - 64)
- | *C* = the carrier designation (A, B, C, D, or E)
- | *SS* = the circuit pack slot number (01, 02,...)
- | *pp* = the 2-digit port number (01, 02,...)
- | *1* = long test sequence
- | *r* = repeat
- | *2* = the number of times the test sequence should be repeated.

The following is an example for testing a port on a media module. It runs the short test sequence:

```
test port GGGVSpp r 3
```

- | *GGG* = the media gateway number (1 - 250)
- | *V* = the literal letter V, which designates a media gateway
- | *S* = the media module number (1 - 9)
- | *pp* = the 2-digit port number (01, 02,...)
- | *r* = repeat
- | *3* = the number of times the test sequence should be repeated

Alarm levels

During normal operations, software or firmware may detect error conditions concerning specific Maintenance Objects (MOs). The system automatically attempts to fix or circumvent the problem. The alarms are classified depending on their effect on system operation:

- | **Major alarms** — Failures that cause critical degradation of service. These alarms require immediate attention.
- | **Minor alarms** — Failures that cause some degradation of service, but do not render a crucial portion of the system inoperable. A minor alarm typically affects a few trunks or stations or a single feature. Minor alarms require attention, but the consequences are not immediate.
- | **Warning alarms** — Failures that cause no significant degradation of service or failures in equipment. These failures are not reported to INADS or the attendant console.
- | **On-Board** problems originate in the circuitry on the alarmed Media Module or circuit pack.

- 1 **Off-Board** problems originate in a process or component that is external to the Media Module or circuit pack.

Alarms are communicated by entries in the alarm log and the turning on of LEDs located on the attendant console, on all circuit packs, on the server, on the Ethernet switch if there is one, and, optionally, on customer-designated voice terminals.

Abort Code 1412

Tests which are not applicable for media modules or media gateways abort with Error Code 1412. This error indicates that the test is not valid for the particular maintenance object and can be ignored.

Escalation Procedure

This document is not intended to solve all problems. If the limits of these procedures have been reached and the problem is not resolved, the problem should be escalated to a higher level of technical support.

This escalation should conform to the procedures in the *Technical and Administration Plan*.

Frequently, a repair procedure recommends repeating a test several times after waiting short time intervals, for example, at one minute intervals up to five times. If, after these repetitions, no response to the test has occurred or if the same Abort or Failure continues to occur, escalate the problem to a higher level of technical support.

EPN Angel Address/Slot Mapping

The following table contains the Angel addresses for EPNs. Note the different mappings for different A-carrier types.

Table 7: EPN Angel Address/Slot Mapping

Slot Number	Carrier								
	A ¹	A ²	A ^{3,4}	B ⁴	C ⁴	D ⁴	E ⁴	D ⁵	E ⁵
0	27	----	90	86	118	54	22	----	----
1	28	30	27	66	98	34	02	----	----
2	29	31	28	67	99	35	03	32	00

6. Service Slot is labeled slot 0, external slot 21

ABRI-POR (ASAI ISDN-BRI Port)

MO Name in Log	Alarm Level	Initial Command to Run	Full MO Name
ABRI-POR ¹	MAJ MIN WRN	<code>test port location 1</code>	ASAI ISDN-BRI port

1. Use **set options** to set the alarm level for ABRI ports. The alarm level can be set independently for on- and off-board alarms to WARNING, MINOR, or MAJOR for every ABRI port in the system.

For repair procedures, see [BRI-PORT \(ISDN-BRI Port\)](#).

AC-POWER

AC Power for AC-Powered Systems

MO Name in Log	Alarm Level	Initial Command to Run	Full Name of MO
AC-POWER	WRN	<code>test environment location¹</code>	AC Power

1. Cabinet number indicated in the `PORT` field of the alarm log.

Three different cabinet types are supported as PNs: multicarrier cabinets, single-carrier cabinets, and the G650 rack mounted cabinets. All types may be powered by either an AC or DC power source. Environmental maintenance differs according to a cabinet's type and its power supply.

 **CAUTION:**

Before powering down a cabinet or carrier that contains an EMBEDDED AUDIX circuit pack (TN566), first power down the AUDIX unit to avoid damaging its software. Instructions for powering down this unit are in *Maintenance Procedures for Avaya Aura™ Communication Manager, Media Gateways and Servers (03-300432)*.

Power System for Single-Carrier Cabinet

Each single-carrier cabinet has one power supply that distributes DC power and AC ringing voltage to the circuit pack slots in the cabinet.

AC Power Supply (WP-91153)

In an AC-powered cabinet, a single, plug-in, multi-output AC power supply is in the power supply slot. A power cord, with a 3-prong plug on one end and an appliance connector on the other end, connects the supply to a dedicated AC power source. The inputs to the power supply can be (depending on list version):

- 1 120 VAC, 60 Hz, 15 to 20 Amp; three wires in the power cord (one hot, one neutral, and one ground wire)
- 1 220 VAC or 240 VAC, 50 Hz, 10 Amp; three wires in the power cord (one hot, one neutral, and one ground wire)

The AC power supply produces the following DC outputs: +5 VDC, -5 VDC, -48 VDC, +12 VDC, and a battery-charging voltage. The DC outputs distribute power on the cabinet backplane to the circuit pack slots.

Communication Manager Maintenance Object Repair Procedures

The AC power supply also produces AC ringing voltage. The AC ringing voltage output value and frequency depend on the country of use. The power supply has a circuit breaker and EMI filtering.

Nominal Power Holdover

Multicarrier Cabinets

Two types of battery holdover are available:

- 1 The small battery assembly provides short-term battery holdover. If AC power fails, 48 VDC batteries power the system for:
 - 15 seconds in a PN cabinet
 - 10 minutes in the expansion control carrier in the “A” position of a PN cabinet
- 1 Some AC-powered multicarrier cabinets (MCCs) contain three 48-Volt batteries and a battery charger (397C) to provide backup power in case power is interrupted. The holdover times are identical to those above.

Single-Carrier Cabinets

A holdover circuit in the power supply allows a system to operate normally during AC power interruptions. When AC input power fails, reserve batteries supply power to the memory and processor circuit packs and fans for two minutes. Every port circuit pack is inactive during this time. The power supply contains a battery charger to charge the holdover batteries.

Error log entries and recommended actions

Table 8: AC-POWER Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Recommended action
0 ¹	0	Any	Any	Any	<i>test environment location</i>
513	Any	AC Power Query Test (#78)	WRN	OFF	<i>test environment location</i>

1. Run the short test sequence first. If every test passes, run the long test sequence. Refer to each appropriate test's description, and follow its recommended procedures.

Demand test descriptions and error codes

Investigate tests in the order presented. By clearing errors associated with the first test, errors generated from other tests may also be cleared. Click on the link to see the full description of the test, error codes, and recommended actions.

Note:

The following tests apply to J58890CE, J58890CF, and J58890CH.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND¹
Battery and Power Supply Query Test (#5)	X	X	ND
AC Power Query Test (#78)	X	X	ND

Ring Generator Initialization Test (#117)	X	X	ND
Ring Generator Query Test (#118)	X	X	ND

1. D = Destructive; ND = Nondestructive

AC-POWER for DC-Powered Systems

MO Name in Log	Alarm Level	Initial Command to Run	Full Name of MO
AC-POWER	WRN	<code>test environment location</code>	AC Power

Note:

In a DC-powered multicarrier cabinet, the AC-POWER MO exists but serves no functional purpose. Because the system cot determine the type of power used, the AC-POWER test should always pass or abort. See [CARR-POW \(Carrier Power Supply\)](#) for the maintenance strategy for power components in DC cabinets.

S8700-series Fiber-PNC supports three cabinet types for PNs: multicarrier cabinets (MCCs), single-carrier cabinets (SCCs), and 19-inch rack mounted cabinets. Every type may be powered by either an AC or DC power source. Environmental maintenance differs according to a cabinet's type and its power supply.

S8700-series IP-PNC supports 19-inch rack mounted cabinets, powered by either an AC or DC power source.

Error log entries and recommended actions

Table 9: AC-POWER Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Recommended action
0 ¹	0	Any	Any	Any	<code>test environment location</code>
513	Any	AC Power Query test (#78)	WRN	OFF	<code>test environment location</code>

1. Run the short test sequence first. If every test passes, run the long test sequence. Refer to each appropriate test's description, and follow its recommended procedures.

1. D = Destructive; ND = Nondestructive

ADM-CONN (Administered Connection)

MO Name in Log	Alarm Level	Initial Command to Run	Full Name of MO
ADM-CONN	MAJ MIN WRN	<code>status administered-connection n</code> ¹	Administered Connection

1. *n* is an administered connection number indicated in the PORT field of the Alarm or Error Log.

An administered connection provides an end-to-end connection between two access endpoints or data modules residing in either the same switch or different switches. When administered, the connection is automatically established and scheduled to be permanently active.

An error is logged whenever an administered connection fails or cot be established. A failed connection generates an error whether or not the connection is subsequently reestablished by fast retry, re-dial, or auto restoration.

An alarm is logged when an administered connection cot be established either initially or after a connection failure. Both the alarm level (none to major) and a failure threshold can be administered for each administered connection. An alarm is raised when either of the following occurs:

- 1 The number of consecutive failed attempts to establish a connection reaches the administered threshold.
- 1 The failure to establish a connection is due to a mistake in administration. See [Table 11: Administered Connection Error Log Entries](#).

Error log entries and recommended actions

					2 of 2

ADM-CONN Errors

None of the Administered Connection Error Types have a specific associated test and, except for errors 17 and 127, are valid only for administered connections established over ISDN-PRI facilities. Error 127 is valid for administered connections established over non-ISDN facilities or between two endpoints on the same switch.

Notes:

- a. **Error Types 1, 16, 22, 50, 52, 65, 66, 69, 88** are typically associated with administration problems and are not expected to be temporary. The administered connection is not retried and the failure is alarmed immediately. The alarm threshold specified by the customer is ignored.
- b. **Error Types 1, 28**: the address of the destination endpoint is: an unassigned number (**1**), has an invalid number format (**28**), or is restricted from terminating calls due to Class of Restriction (“Access Denied”). Verify that the destination address is correct and that the destination endpoint is administered. The destination endpoint is not administered on the switch where this error is logged.

Communication Manager Maintenance Object Repair Procedures

- c. **Error Type 2:** a request has been made to use a transit network or common carrier that cannot be accessed. Check the routing pattern used by this administered connection and verify that the inter-exchange carrier specified is correct.
- d. **Error Types 6, 21, 31, 127:** the exact failure cause is unknown or has been mapped to one of these values. If this is a permanent condition, try reversing the direction of the Administered Connection (originate the administered connection from the destination switch). This may yield another failure cause.
- e. **Error Type 17:** the destination endpoint is not available. Check the status of the destination endpoint at the far-end switch. The status for the destination endpoint will not be available on the switch where this error is logged. At the far end, use `status access-endpoint` or `status data-module` to see whether the endpoint is busy, out-of-service, or otherwise unavailable.
- f. **Error Types 18, 102:** this switch sent an ISDN message to another switch that either did not respond (**18**) or did not respond within the time allowed (**102**). This could be due to link failure, or congestion, or an outage at the other switch.
- g. **Error Type 22:** the address of the destination endpoint has changed. Change the administered connection accordingly. The destination endpoint will not be administered on the switch where this error is logged.
- h. **Error Types 34, 42, 44, 58:** a resource (for example, a circuit or bearer capability) required by the administered connection is not currently available.
- i. **Error Types 38, 41:** a network failure (**38**) or temporary failure (**41**) has occurred. Error Log entries for other MOs (for example, DS1-BD) may indicate a local problem.

ADX8D-BD (AUDIX Circuit Pack)

MO Name in Log	Alarm Level	Initial Command to Run	Full Name of MO
ADX8D-BD	MIN WRN	<i>test board location</i>	AUDIX circuit pack

The ADX8D-BD MO defines a TN566/TN2169 EMBEDDED AUDIX circuit pack operating in DP (digital-port) mode.

For port-level problems, see [ADX8D-PT \(AUDIX Digital Port\)](#).

For circuit-pack-level problems, see [XXX-BD \(Common Port Circuit Pack/Media Module\)](#).

EMBEDDED AUDIX consists of two circuit packs that occupy 5 slots on a port carrier. The tests apply only to switch-side maintenance which tests a circuit pack's components related to the TDM-bus interface. The AUDIX system has an extensive maintenance strategy that is described in *DEFINITY® AUDIX Maintenance*.

ADX8D-PT (AUDIX Digital Port)

MO Name in Log	Alarm Level	Initial Command to Run	Full Name of MO
ADX8D-PT	MIN	<code>test port location 1</code>	AUDIX digital port
	WRN	<code>test port location</code>	

The ADX8D-PT MO represents a port on a TN566/TN2169 EMBEDDED AUDIX circuit pack operating in DP (digital-port) mode. The maintenance strategy for ports on the TN566 operating in control-link mode is described in [ADX16D-P \(16-Port AUDIX Digital Port\)](#).

The tests apply only to switch-side maintenance that tests a circuit pack’s components related to the TDM-bus interface. The AUDIX system has an extensive maintenance strategy that is described in *DEFINITY® AUDIX Maintenance*.

AUDIX resides on a combined pair of circuit packs: the TN566 MFB (multifunction board) and the TN2169 ALB (alarm board). The 2 boards occupy 5 slots, but only 1 slot is functional as far as the switch is concerned. The other 4 slots are seen by the switch as “AUDIX-reserved” slots (or ADXDP-RS/ADX8D-RS).

In DP mode, the TN566 pack supports up to 8 voice ports, each with a primary and a secondary information channel. Ports are administered in increments of two. When a call to a station with an AUDIX login is not answered, AUDIX answers the call using one of the available voice ports.

Unlike other AUDIX systems, EMBEDDED AUDIX is not an adjunct.

 **CAUTION:**

Always shut down AUDIX first before removing circuit packs. Follow instructions on the TN566/TN2169 faceplate:

- 1 Remove EMBEDDED AUDIX circuit packs
- 1 Cycle power to a carrier containing EMBEDDED AUDIX circuit packs
- 1 Remove power to a carrier containing EMBEDDED AUDIX circuit packs

Error log entries and recommended actions

					2 of 2

1. Minor alarms on this MO may be downgraded to Warning alarms based on the values used in **set options**.

Notes:

- a. **Error Type 0**: run the short test sequence. If every test passes, run the long test sequence. Refer to each appropriate test's description, and follow its recommended procedures.
- b. **Error Type 1, Aux Data 40987**: the user may experience a noisy port or link due to an off-board problem. If so, replace the circuit pack (see caution at the beginning of this section). Once the problem is resolved, the alarm is retired after a predetermined time.
- c. **Error Type 1, Aux Data 1 to 20**: At least 15 off-board problems have been detected with the link to the voice port. Also see Note (a).
- d. **Error Type 15**: internal error that occurs when an audit request fails.

Communication Manager Maintenance Object Repair Procedures

- e. **Error Type 18:** the port is busied-out by command. Enter `release port location` to release the port.
- f. **Error Type 23:** the circuit pack is administered but not physically installed. The alarm will clear when a circuit pack is inserted.
- g. **Error Type 130:** the circuit pack was removed or has been insane for more than 21 minutes. To clear the error, reinsert or replace the AUDIX circuit pack (see Caution at the beginning of this section).
- h. **Error Type 257:** Something is interfering with transmission to the voice port. This is usually an on-board problem and can be ignored if there are no user complaints.
- i. **Error Type 513:** AUDIX is not available to the switch, possibly due to a busyout on the AUDIX system. See *DEFINITY® AUDIX Maintenance*, if necessary.
- j. **Error Type 1537:** There is a problem with the link to the voice port. This error can be ignored if there are no user complaints. If the problem persists, replace the circuit pack (see Caution at the beginning of this section). Once the problem is resolved, the alarm is retired after a certain period of time.
- k. **Error Type 2305:** the link between the circuit pack and the voice port successfully reset. No action is necessary.
- l. **Error Type 3840, Aux Data 40965:** no voice ports are connected to the EMBEDDED AUDIX circuit pack. No maintenance action is required.
- m. **Error Type 3840, Aux Data 41029:** the message buffer in the circuit pack is full.

Demand test descriptions and error codes

Investigate tests in the order presented. By clearing errors associated with the first test, errors generated from other tests may also be cleared. Click on the link to see the full description of the test, error codes, and recommended actions.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND ¹
Local Loop Test (#13)		X	ND
GPP NPE Crosstalk Test (#9)		X	ND

1. D = Destructive; ND = Nondestructive

ADX8D-RS (AUDIX Reserve Slots)

See [AXA12-RS \(AUDIX Reserve Slots\)](#).

ADX16A-B (AUDIX Circuit Pack)

MO Name in Log	Alarm Level	Initial Command to Run	Full Name of MO
ADX16A-B	MIN WRN	<i>test board location</i>	AUDIX circuit pack

The ADX16A-B MO represents a TN566/TN2169 EMBEDDED AUDIX circuit pack combination operating in control-link (CL) mode.

For circuit-pack-level problems, see [XXX-BD \(Common Port Circuit Pack/Media Module\)](#).

Port-level maintenance is covered by [AESV-LNK \(AE Services Link\)](#).

EMBEDDED AUDIX consists of two circuit packs that occupy 5 slots on a port carrier. The tests apply only to switch-side maintenance that tests a circuit pack's components related to the TDM-bus interface. The AUDIX system has an extensive maintenance strategy that is described in *DEFINITY® AUDIX Maintenance*.

ADX16A-P (AUDIX Analog Line/Control Link)

MO Name in Log	Alarm Level	Initial Command to Run	Full Name of MO
ADX16A-P	MIN	<code>test port location 1</code>	AUDIX Analog Line/ Control Link
	WRN	<code>test port location</code>	

 **CAUTION:**

Never do any of the following without first shutting down AUDIX. Follow the instructions on the TN566/TN2169 faceplate:

- 1 Remove EMBEDDED AUDIX circuit packs
- 1 Cycle power to a carrier containing EMBEDDED AUDIX circuit packs
- 1 Remove power to a carrier containing EMBEDDED AUDIX circuit packs

The ADX16A-P MO represents a port on a TN566/TN2169 EMBEDDED AUDIX circuit pack that is operating in control-link (CL) mode.

For circuit-pack-level problems (ADX16A-B or ANL-16-B), see [XXX-BD \(Common Port Circuit Pack/Media Module\)](#).

For port-level problems with AUDIX operating in digital-port mode, see:

- 1 [ADX8D-PT \(AUDIX Digital Port\)](#)
- 1 [ADX16D-P \(16-Port AUDIX Digital Port\)](#)

The tests apply only to switch-side maintenance that tests a circuit pack's components related to the TDM-bus interface. The AUDIX system has an extensive maintenance strategy that is described in *DEFINITY® AUDIX Maintenance*.

AUDIX resides on a combined pair of circuit packs: the TN566 Multifunction board (MFB) and the TN2169 Alarm board (ALB). The 2 boards occupy 5 slots, but only 1 slot is functional as far as the switch is concerned. The other 4 slots are seen by the switch as "AUDIX-reserved" slots.

In CL mode, the TN566 pack supports up to 16 voice ports. When a call to a station with an AUDIX login is not answered, AUDIX answers the call using one of the available voice ports.

Unlike other AUDIX systems, EMBEDDED AUDIX is not an adjunct.

Error log entries and recommended actions

Table 13: ADX16A-P Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Recommended action
0 ¹	0	Any	Any	Any	<i>test port location</i>
1 (a)	40977	None			
18	0	<i>busyout station ext</i>	WRN	ON	<i>release station extension</i>
23 (b)	0	None	WRN	OFF	
130 (c)		None	WRN	ON	<i>test port location</i>
257 (d)	40973	None			
513 (e)	Any	None			
1025 (f)		Looparound Test (#161)	MIN WRN ²	ON	<i>test port location 1 r 2</i>
1281		Conference Circuit Test (#7)	MIN WRN ²	ON	<i>test port location 1 r 2</i>
1537		NPE Crosstalk Test (#6)	MIN WRN ²	ON	<i>test port location 1 r 2</i>

1. Run the short test sequence first. If every test passes, run the long test sequence. Refer to each appropriate test's description, and follow its recommended procedures.

2. Minor alarms on this MO may be downgraded to Warning alarms based on the values used in **set options**.

Notes:

- a. **Error Type 1** is an inline error that can only be resolved over time. No terminal equipment was present when ringing was attempted. Execute *test port location*
- b. **Error Type 23**: The circuit pack was logically administered but not physically installed. The alarm will clear when the circuit pack is installed.
- c. **Error Type 130**: The circuit pack was removed or has been insane for more than 11 minutes. To clear the error, reseal or replace the circuit pack.

- d. **Error Type 257** is an inline error and can only be resolved over time. Ringing voltage is absent. If only one analog circuit pack in the system has this problem, replace the circuit pack. If only analog circuit packs on a particular carrier have this error, the ringing generator may not be connected to this carrier. If analog circuit packs on many carriers have this error, check the ringing generator.
- e. **Error Type 513**: AUDIX is not available to the switch. Check the **AUDIX** system, referring to *DEFINITY® AUDIX Maintenance*.
- f. **Error Type 1025**: The **TDM** bus is out of service. See [TDM-BUS \(TDM Bus\)](#).

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND ¹
Analog Looparound Test (#161)		X	ND
Conference Circuit Test (#7)		X	ND
NPE Crosstalk Test (#6)		X	ND

1. D = Destructive; ND = Nondestructive

Tests 36 and 48 ABORT when AUDIX is not running.

ADX16D-B (16-Port AUDIX Circuit Pack)

MO Name in Log	Alarm Level	Initial Command to Run	Full Name of MO
ADX16D-B	MIN WRN	<i>test board location</i>	AUDIX circuit pack

The ADX16D-B MO represents a TN566/TN2169 EMBEDDED AUDIX circuit pack combination operating in 16-port mode digital (DP).

For circuit-pack-level problems, see [XXX-BD \(Common Port Circuit Pack/Media Module\)](#).

Port-level maintenance is covered by [ADX16D-P \(16-Port AUDIX Digital Port\)](#).

EMBEDDED AUDIX consists of two circuit packs that occupy 5 slots on a port carrier. The tests apply only to switch-side maintenance that tests a circuit pack's components related to the TDM-bus interface. The AUDIX system has an extensive maintenance strategy of its own that is described in *DEFINITY® AUDIX Maintenance*.

ADX16D-P (16-Port AUDIX Digital Port)

MO Name in Log	Alarm Level	Initial Command to Run	Full Name of MO
ADX16D-P	MIN WRN	<code>test port location 1</code>	AUDIX Digital port

 **CAUTION:**

Never do any of the following without first shutting down AUDIX. Follow the instructions on the TN566/TN2169 faceplate:

- 1 Remove EMBEDDED AUDIX circuit packs
- 1 Cycle power to a carrier containing EMBEDDED AUDIX circuit packs
- 1 Remove power to a carrier or cabinet containing EMBEDDED AUDIX circuit pack

The ADX16D-P MO represents a port on a TN566/TN2169 EMBEDDED AUDIX circuit pack operating in digital-port (DP) mode. The maintenance strategy for ports on the TN566 operating in control-link mode is described in [ADX16A-P \(AUDIX Analog Line/Control Link\)](#).

The tests apply only to switch-side maintenance that tests a circuit pack's components related to the TDM-bus interface. The AUDIX system has an extensive maintenance strategy that is described in *DEFINITY® AUDIX Maintenance*.

AUDIX resides on a combined pair of circuit packs: the TN566 Multifunction board (MFB) and the TN2169 Alarm board (ALB). The 2 boards occupy 5 slots, but the system sees only 1 slot as functional. The other 4 slots are seen by the switch as "AUDIX-reserved" slots (or ADX16-RES/ADX16D-RS).

In 16-port DP mode, the TN566 pack supports up to 16 voice ports, each with a primary and a secondary information channel. Ports are administered in increments of two. When a call to a station with an AUDIX login is not answered, AUDIX answers the call using one of the available voice ports.

Unlike other AUDIX systems, EMBEDDED AUDIX is not an adjunct.

Error log entries and recommended actions

Table 14: ADX16D-P Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Recommended action
0 (a)	0	Any	Any	Any	<i>test port location</i>
1 (b)	40987		WRN	OFF	
1 (c)	1 to 20		WRN	OFF	
15 (d)	Any				
18 (e)	0	<i>busyout port location</i>	WRN	OFF	<i>release port location</i>
23 (f)	0		WRN	OFF	
130 (g)			WRN	ON	<i>test port location</i>
257 (h)	40971				
513 (i)	Any				
1537 (j)	40968		WRN	OFF	
1793		Voice and Control Local Loop Test (#13)	MIN WRN ¹	ON	<i>test port location 1 r 3</i>

2305 (k)	40967				
3840 (l)	40965				
3840 (m)	41029				

1. Minor alarms may be downgraded to Warning alarms based on the values used in **set options**.

Notes:

- a. **Error Type 0**: run the short test sequence first. If every test passes, run the long test sequence. Refer to each test's description, and follow the recommended procedures

- b. **Error Type 1 with Aux Data 40987:** The user may experience a noisy port or link, due to an off-board problem that is detected by the port circuit. If so, replace the circuit pack (see caution at the beginning of this section). Once the problem is resolved, the alarm is retired after a predetermined time.
- c. **Error Type 1:** At least 15 off-board problems have been detected with the link to the voice port. When an error with the link is detected, an on-board counter is incremented. Also see Note a above.
- d. **Error Type 15:** An audit request failed - internal error.
- e. **Error Type 18:** The port is busied-out by command. Release the port with **release port location**.
- f. **Error Type 23:** The circuit pack is administered but not physically installed. The alarm will clear when a circuit pack is inserted.
- g. **Error Type 130:** The circuit pack has been removed or has been insane for more than 21-minutes. To clear the error, reseal or replace the AUDIX circuit pack (see caution at the beginning of this section).
- h. **Error Type 257:** Something is interfering with transmission to the voice port. This is usually an on-board problem and can be ignored if there are no user complaints.
- i. **Error Type 513:** AUDIX is not available to the switch, possibly due to a busyout on the AUDIX system. Refer to *DEFINITY® AUDIX Maintenance*.
- j. **Error Type 1537:** There is a problem with the link to the voice port. This can be ignored if there are no user complaints. If the problem persists, replace the circuit pack (see caution at the beginning of this section). Once the problem is resolved, the alarm is retired after a certain period of time.
- k. **Error Type 2305:** The link between the circuit pack and the voice port is successfully reset. No action is necessary.
- l. **Error Type 3840 with Aux Data 40965:** No voice ports are connected to the EMBEDDED AUDIX circuit pack. No action is required.
- m. **Error Type 3840 with Aux Data 41029:** The message buffer in the circuit pack is full.

Demand test descriptions and error codes

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND ¹
Local Loop Test (#13)		X	ND
GPP NPE Crosstalk Test (#9)		X	ND

1. D = Destructive; ND = Nondestructive

AESV-LNK (AE Services Link)

MO Name in Log	Alarm Level	Initial Command to Run	Full Name of MO
AESV-LNK	MAJ WRN	<code>test aesvcs-server</code>	Application Enablement Services (AESVCS) Link

AESVCS Links provide a connection between Communication Manager and an AESVCS Server in which data is exchanged. Communication Manager dynamically creates and deletes AESVCS Links as socket connections to the AESVCS Server are established and torn down. AESVCS Links that are connected to the same AESVCS Server are grouped into an AESVCS Session.

Error log entries and recommended actions

Table 15: AESV-LNK Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Recommended action
513 (a)			WRN	Off	none
769 (b)		AESVCS Link Heartbeat Test (#1624)	Log only		<code>test aesvcs link link#</code>
1537 (c)	Any		Log only		
2561 (d)			Log only		

Notes:

- a. **Error Type 513** is displayed when an AESVCS Link is hyperactive. The hyperactivity might be caused by fluctuations in the engineered traffic load being generated by the AESVCS Server. Both an AESVCS Session level and Link level alarm are generated to indicate that a link is overloaded.

Once the problem has been resolved, it might take up to 45 minutes for the alarm to clear. If the hyperactivity persists, escalate the problem.

- b. **Error type 769** is a log only error and is displayed when Communication Manager does not receive a response from the AESVCS Server to a heartbeat message that was sent over

Communication Manager Maintenance Object Repair Procedures

the AESVCS Link. Failure to receive a response to a heartbeat message results in the deletion of the AESVCS Link by Communication Manager. Both an AESVCS Session Level and Link level error are generated against this condition. Escalate if the error persists.

- c. **Error type 1537** is a log only error and displayed when an AESVCS Link is deleted from an AESVCS Session for reasons other than a heartbeat failure. Both an AESVCS Session Level and Link level error are generated against this condition. The Aux Data field contains the reason code.

Aux Data	Description
1	The far end closed the socket connection. Check the error logs on the AEVCS Server for more information.
100	The <code>reset aecvcs-link</code> command was used to close the socket connection
101	The AESVCS Interface on the IP Services form was disabled.
102	The AESVCS Interface was removed from the IP Services form.
103	The AE Services Server was disabled on the AE Services Administration page of the IP Services form.
104	The AE Services Server was deleted on the AE Services Administration page of the IP Services form.
200	The socket connection closed due to an internal error. Escalate if the problem persists.
201	The socket connection was unexpectedly closed by Communication Manager. Escalate if the problem persists.
202	Communication Manager detected an error and closed the socket connection. Escalate if the problem persists.
203	Communication Manager detected an error reading from the socket and closed the connection. Escalate if the problem persists.
204	Communication Manager failed to write a complete message and closed the socket connection. Escalate if the problem persists.
205	AE Server established a new connection causing Communication Manager to close the existing one. Escalate if the problem persists.
206	Communication Manager failed to send a heartbeat request and closed the socket connection. Escalate if the problem persists.
207	Communication Manager detected a protocol violation and closed the socket connection. Escalate if the problem persists.
1 of 2	

Aux Data	Description
208	Communication Manager detected processing the data from the AESVCS Server and closed the socket connection. Escalate if the problem persists.
209	Communication Manager could not read data from the socket and closed the connection. Escalate if the problem persists.
2 of 2	

- d. **Error Type 2561** is a log only error and is displayed when an AESVCS message is discarded due to a link buffer overflow. Both an AESVCS Session Level and Link level error is generated against this condition. Escalate if the problem persists.

Demand test descriptions and error codes

Investigate tests in the order presented. By clearing errors associated with the first test, errors generated from other tests may also be cleared. Click on the link to see the full description of the test, error codes, and recommended actions.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND ¹
AESVCS Link Heartbeat Test (#1624)	X	X	ND
AESVCS Session Level Link Status Test (#1623)	X	X	ND

1. D = Destructive; ND = Nondestructive

AESV-SES (AE Services Session)

MO Name in Log	Alarm Level	Initial Command to Run	Full Name of MO
AESV-SES	MAJ WRN	<code>test aesvcs-server</code>	Application Enablement Services Session

An AESVCS Session is a logical connection between Communication Manager and a single AESVCS Server, and encompasses all the AESVCS Links that are connected between them.

Error log entries and recommended actions

Table 16: AESV-SES Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Recommended action
513 (a)	1-16		WRN	Off	none
769 (b)	1-16	AESVCS Link Heartbeat Test (#1624)	Log only		
1025 (c)	1-16		MAJ	Off	<code>test aesvcs-server</code>
1537 (d)	1-16		Log only		
2561 (e)	1-16		Log only		

Notes:

- a. **Error Type 513** occurs when one or more AESVCS Links within a given AESVCS Session is hyperactive. The hyperactivity might be caused by fluctuations in the engineered traffic load being generated by the AESVCS Server. Both an AESVCS Session Level and Link level alarm is generated to indicate that a link is overloaded. The Aux Data field contains the link ID of the last AESVCS Link to report hyperactivity.

Once the problem has been resolved, it might take up to 45 minutes for the alarm to clear. Refer to [AESV-LNK \(AE Services Link\)](#) for more information.

- b. **Error type 769** is a log only error and is displayed when Communication Manager detects a heartbeat failure on one or more AESVCS Links within the AESVCS Session. The Aux Data field contains the link ID of the last AESVCS Link to report a heartbeat failure. An AESVCS

Link level error is also generated against this condition. Refer to [AESV-LNK \(AE Services Link\)](#) for more information.

- c. **Error Type 1025** is displayed when no AESVCS Links are left in an AESVCS Session. This alarm is cleared when Communication Manager associates a new AESVCS Link to the session. The Aux Data field contains the link ID of the last AESVCS Link deleted from the session.
- d. **Error type 1537** is a log only error and is displayed when one or more AESVCS Links, within the AESVCS Session is deleted for reasons other than a heartbeat failure. The Aux Data field contains the link ID of the last AESVCS Link deleted from the session. An AESVCS Link level error is also generated against this condition. Refer to [AESV-LNK \(AE Services Link\)](#) for more information.
- e. **Error Type 2561** is a log only error and is displayed when one or more AESVCS Links within the AESVCS Session is discarding messages due to a link buffer overflow. This error represents the sum of all the discarded messages in a given session. The Aux Data field contains the link id of the last AESVCS Link, within the session, to discard a message. An AESVCS Link level error is also generated against this condition. Refer to [AESV-LNK \(AE Services Link\)](#) for more information.

Demand test descriptions and error codes

1. D = Destructive; ND = Nondestructive

ALARM-PT (Alarm Port)

MO Name in Log	Alarm Level	Initial Command to Run	Full Name of MO
ALARM-PT	MIN	<i>test port location 1</i>	Alarm Port
	WRN	<i>test port location</i>	

The Alarm Port MO provides on-board maintenance for an analog line port that is administered as an external device alarm port. Tests are provided to verify the analog line port's ability to detect an external device alarm. The related MO, [EXT-DEV ADMIN? Y \(External Device Alarm\)](#), is used for the off-board external device alarm.

Error log entries and recommended actions

Table 17: ALARM-PT Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Recommended action
0 (a)	0	Any	Any	Any	<i>test port location</i>
15 (b)	Any	Port Audit and Update (#36)			
18	0	<i>busyout station extension</i>	WRN	OFF	<i>release station extension</i>
130 (c)		None	WRN	ON	<i>test port location</i>

Notes:

- a. **Error Type 0:** Run the short test sequence first. If every test passes, run the long test sequence. Refer to each appropriate test's description, and follow its recommended repair procedures.
- b. **Error Type 15:** software audit error that does not indicate any hardware malfunction. Run the short test sequence and investigate errors.
- c. **Error Type 130:** the circuit pack or media module was removed or has been insane for more than 11 minutes. To clear the error, reset or replace the circuit pack or media module.

Demand test descriptions and error codes

Investigate tests in the order presented. By clearing errors associated with the first test, errors generated from other tests may also be cleared. Click on the link to see the full description of the test, error codes, and recommended actions.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND ¹
Port Diagnostic Test (#35)	X	X	ND
Port Audit And Update Test (#36)	X	X	ND

1. D = Destructive; ND = Nondestructive

AN-LN-PT (Analog Line Port)

MO Name in Log	Alarm Level	Initial Command to Run	Full Name of MO
AN-LN-PT	MIN	<code>test port location 1</code>	Analog Line port
	WRN	<code>test port location</code>	

The TN793B/TN2793B Analog Line circuit pack (w/ Caller ID) provides 24 ports for voice terminals and supports both on-premises and off-premises analog voice terminals.

The TN797 Analog Trunk and Line circuit pack provides 8 ports, each of which may be administered in any of several ways, as described in [TR-LN-BD \(Analog Trunk/Line Board\)](#).

The MM711 Analog Trunk and Line Media Module provides 8 ports. The MM716 provides 24 ports. Each of the ports may be administered in any of several ways, as described in [MG-ANA \(Analog Media Module\)](#). Not all of the tests that run on the circuit packs are applicable to the media modules. These tests will abort with error code 1412. This error can be ignored.

Ringling caused by maintenance testing

Test #48 may cause some terminal equipment to ring briefly during daily maintenance. If this ringing disturbs the customer or the terminal equipment, disable it in the `Tests` field of the `change station extension` form. Be aware that this action also disables Tests #6, 7, 161, and 35 on some software releases.

Error log entries and recommended actions

Table 18: AN-LN-PT Error log entries 1 of 2

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Recommended Action
0 (a)	0	Any	Any	Any	<code>test port location</code>
1 (b)	40960 40975 40977	none			
15 (c)	Any	Port Audit and Update (#36)			
18	0	<code>busy station extension</code>	WRN	ON	<code>release station extension</code>
130 (d)		None	WRN	ON	<code>test port location</code>
					1 of 2

Table 18: AN-LN-PT Error log entries 2 of 2

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Recommended Action
257 (e)	40973	None			
513 (f)		Ringing Application Test (#48)	WRN	OFF	<code>test port location r 2</code>
769		Port Diagnostic Test (#35)	MIN WRN ¹	ON	<code>test port location r 2</code>
1025		Looparound test (#161)	MIN WRN2	ON	<code>test port location 1 r 2</code>
1281		Conference Circuit Test (#7)	MIN WRN2	ON	<code>test port location 1 r 2</code>
1537		NPE Crosstalk Test (#6)	MIN WRN2	ON	<code>test port location 1 r 2</code>
					2 of 2

1. Minor alarms on this MO may be downgraded to Warning alarms based on the values used in **set options**.

Notes:

- a. **Error type 0:** Run the short test sequence first. If every test passes, run the long test sequence. Refer to each appropriate test's description, and follow its recommended procedures.
- b. **Error Type 1:** these are inline errors and can only be resolved over time.
 1. Aux Data 40960 indicates that too many simultaneous incoming ringing attempts were made on this board. Only 4 ports on a board may ring simultaneously. A 5th incoming call causes an inline error from the board.
 1. Aux Data 40975 indicates that the terminal equipment was on-hook when ring-tip was detected during ringing. This usually indicates a failure in the terminal equipment or the type of terminal has a low ringer impedance.
 1. Call the terminal equipment and verify that the terminal rings.
 2. If the terminal does not ring, replace it. Otherwise, run `test port location`, and follow the procedure for [ONS Ringer Application Test \(#48\)](#).
 1. Aux Data 40977 indicates that no terminal equipment was connected when ringing was attempted. Run `test port location`, and follow the procedure for the results of [ONS Ringer Application Test \(#48\)](#).
- c. **Error Type 15:** software audit error that does not indicate any hardware malfunction. Run the short test sequence, and investigate any associated errors.
- d. **Error Type 130:** the circuit pack or media module has been removed or has been insane for more than 11 minutes. To clear the error, reseal or replace the circuit pack or media module.

Communication Manager Maintenance Object Repair Procedures

e. **Error Type 257:** this is an inline error and can only be resolved over time. This error indicates that ringing voltage is absent.

For media modules: If not resolved over time, replace the media module.

For circuit packs:

- 1 If only 1 analog circuit pack in the system has this problem, replace the circuit pack.
- 1 If only analog circuit packs on a particular carrier have this error, the ringing generator may not be connected to this carrier.
- 1 If analog circuit packs on many carriers have this error, it is probably a problem with the ringing generator.

f. **Error Type 513:** Test #48 can cause some terminal equipment to ring briefly during daily maintenance. If this disturbs the customer or the terminal equipment, disable it by setting the `Tests` field on the **change station extension** form to **n**. In some software releases, this also disables Tests #6, 7, 161, and 35.

Demand test descriptions and error codes

Investigate tests in the order presented. By clearing errors associated with the first test, errors generated from other tests may also be cleared. Click on the link to see the full description of the test, error codes, and recommended actions.

Port Diagnostic Test (#35)	X	X	ND
ONS Ringer Application Test (#48)	X	X	ND
Analog Looparound Test (#161)		X	ND
Conference Circuit Test (#7)		X	ND
NPE Crosstalk Test (#6)		X	ND
Port Audit And Update Test (#36)	X	X	ND

1. D = Destructive; ND = Nondestructive

ANL-16-L (16-Port Analog Line)

MO Name in Log	Alarm Level	Initial Command to Run	Full Name of MO
ANL-16-L	MIN	<code>test port location 1</code>	16-Port Analog Line
	WRN	<code>test port location</code>	

The circuit packs listed below provide 16 analog line ports for single-line voice terminals. The table below indicates which circuit packs are equipped with lightning protection (for off-premises, out-of -building stations), and which ones support the neon message waiting lamp feature.

16-Port Analog Line Circuit Packs		
Circuit Pack	Off- Premises	Neon
TN468B	y	
TN479		
TN746		y
TN746B	y	y
TN2135	y	
TN2144	y	
TN2149	y	
TN2180	y	

S8700 Series | S8500

These circuit packs provide 16 ports for analog voice terminals. The TN746, TN468, and TN749 support only single-line, on-premises/in-building, analog voice terminals, and not off-premises stations, since these circuit packs are not equipped with lightning protection. The TN746B, TN2144, TN2149, and TN468B support both on-premises and off-premises (that is, out-of-building) analog voice terminals. The TN468, TN468B, TN479, TN2135, TN2144, and TN2149 do NOT support the neon message waiting feature.

No maintenance of the terminal connected to the 16-Port Neon Analog Line circuit pack is performed, except to determine whether or not the terminal is connected. Failures of the neon message waiting lamp power and the common ringing application circuitry are reported as part of common port circuit pack errors. See errors 1281 and 1793 in [XXX-BD \(Common Port Circuit Pack/Media Module\)](#).

Ringling Caused by Maintenance Testing

Test #48 may cause some terminal equipment to ring briefly during daily maintenance. If this ringing is disturbing the customer or the terminal equipment, it should be disabled in the `Tests` field of the `change station extension` screen. Be aware that this action will also disable Tests #6, 7, 161, and 35.

Error log entries and recommended actions

Table 19: ANL-16-L Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/ Off Board	Recommended action
0 (a)	0	Any	Any	Any	<code>test port location</code>
1(b)	40960 40975 40977				
15(c)	Any	Port Audit and Update (#36)			
18	0	<code>busyout station extension</code>	WRN	ON	<code>release station extension</code>
130(d)			WRN	ON	<code>test port location</code>

513(f)		Ringling Application Test (#48)	WRN	OFF	<code>test port location r 2</code>
769		Port Diagnostic Test (#35)	MIN WRN ¹	ON	<code>test port location r 2</code>
1025		Looparound (#161)	MIN WRN ₁	ON	<code>test port location 1 r 2</code>
1281		Conference Circuit Test (#7)	MIN WRN ₁	ON	<code>test port location 1 r 2</code>
1537		NPE Crosstalk Test (#6)	MIN WRN ₁	ON	<code>test port location 1 r 2</code>

1. Minor alarms on this MO may be downgraded to Warning alarms based on the values used in `set options`.

Communication Manager Maintenance Object Repair Procedures

Notes:

- a. **Error Type 0:** Run the short test sequence first. If every test passes, run the long test sequence. Refer to each appropriate test's description, and follow its recommended procedures.
- b. **Error Type 1:** These are inline errors and can only be resolved over time.
 - Aux Data 40960:** too many simultaneous incoming ringing attempts were made on this board. Only 4 ports on a board may ring simultaneously. A 5th incoming call causes an inline error from the board.
 - Aux Data 40975:** the terminal equipment was on-hook when ring-tip was detected during ringing. This usually indicates a failure in the terminal equipment or the type of terminal has a low ringer impedance. Call the terminal equipment and verify that the terminal rings. If the terminal does not ring, replace it. Otherwise, enter `test port location`, and follow the procedure for [ONS Ringer Application Test \(#48\)](#).
 - Aux Data 40977:** no terminal equipment was connected when ringing was attempted. Run the short test via `test port location`, and follow the procedure for the results of [ONS Ringer Application Test \(#48\)](#).
- c. **Error Type 15:** software audit error that does not indicate any hardware malfunction. Run the short test sequence, and investigate associated errors.
- d. **Error Type 130:** the circuit pack has been removed or has been insane for more than 11 minutes. To clear the error, reseal or replace the circuit pack.
- e. **Error Type 257:** ringing voltage is absent.
 - If only 1 analog circuit pack in the system has this problem, replace the circuit pack.
 - If only analog circuit packs on a particular carrier have this error, the ringing generator may not be connected to this carrier.
 - If analog circuit packs on many carriers have this error, there may be a problem with the ringing generator.
- f. **Error Type 513:** Associated Test #48 may cause some terminal equipment to ring briefly during daily maintenance. If this disturbs the customer or the terminal equipment, disable it by setting the `Tests` field on the `change station extension` screen to `n`. On some software releases, this will also disable Tests #6, 7, 161, and 35.

Demand test descriptions and error codes

Investigate tests in the order presented. By clearing errors associated with the first test, errors generated from other tests may also be cleared. Click on the link to see the full description of the test, error codes, and recommended actions.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND ¹
Port Diagnostic Test (#35)	X	X	ND
ONS Ringer Application Test (#48)	X	X	ND
Analog Looparound Test (#161)		X	ND
Conference Circuit Test (#7)		X	ND
NPE Crosstalk Test (#6)		X	ND
Port Audit And Update Test (#36)	X	X	ND

1. D = Destructive; ND = Nondestructive

ANL-BD (Analog Line Circuit Pack)

MO Name in Log	Alarm Level	Initial Command to Run	Full Name Of MO
ANL-BD	MIN WRN	<code>test board location</code>	Analog Line circuit pack

See [XXX-BD \(Common Port Circuit Pack/Media Module\)](#) for circuit pack-level errors.

See [ANL-16-L \(16-Port Analog Line\)](#) or [ANL-LINE \(8-Port Analog Line\)](#) for related line information.

ANL-LINE (8-Port Analog Line)

MO Name in Log	Alarm Level	Initial Command To Run	Full Name of MO
ANL-LINE	MIN	<code>test port location 1</code>	8-Port Analog Line
	WRN	<code>test port location</code>	
ANL-NE-L	MIN	<code>test port location 1</code>	8-Port Neon Analog Line
	WRN	<code>test port location</code>	

Error log entries and tests apply to ANL-LINE and ANL-NE-L.

The 8-port Analog Line circuit packs,

TN411	TN443	TN467
TN712	TN742	TN769

provide eight ports for single-line, on or off-premises analog endpoints such as analog voice terminals, queue warning level lamps, recorded announcements, dictation machines, PAGEPAC paging equipment, external alerting devices, modems, fax machines, and AUDIX voice ports. Only the TN769 supports a neon message waiting lamp.

Note:

PAGEPAC™ is a registered trademark of Harris Corporation, Dragon Division.

Test #48 may cause some terminal equipment to ring briefly during daily maintenance, which may disturb the customer or the terminal equipment. Test #47 may cause a false alarm when the port is connected to certain off-premises equipment, non-voice terminal equipment, or loop equipment. In either case, the tests can be disabled by entering **n** in the `Tests` field on the `change station extension` screen. Be aware that this will disable Tests 6, 35, 47, and 48.

No maintenance of the terminal connected to the 8-Port Analog Line circuit pack or 8-Port Neon Analog Line circuit pack is performed, except to determine whether or not the terminal is connected. Failures of the common ringing application circuitry and the neon message waiting lamp power (ANL-NE-L only) are reported as errors 1281 and 1793 against XXX-BD (Common Port Circuit Pack) in [Common Port Circuit Pack Maintenance Error Log Entries](#).

Error log entries and recommended actions

Table 20: ANL-LINE Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Recommended Action
0 (a)	0	Any	Any	Any	<i>test port location</i>
1 (b)	40960 40975 40977				
15 (c)	Any	Port Audit and Update Test (#36)			
18	0	<i>busyout station extension</i>	WRN	OFF	<i>release station extension</i>
130 (d)			WRN	ON	<i>test port location</i>

1281 (g)					
1793 (g)					

1. Minor alarms on this MO may be downgraded to Warning alarms based on the values used in **set options**.

Notes:

- a. Error Type 0: Run the short test sequence first. If every test passes, run the long test sequence. Refer to each appropriate test's description, and follow its recommended procedures.

b. **Error Type 1:** These are inline errors that are resolved over time by the system.

Aux Data 40960: too many simultaneous incoming ringing attempts were made on this board. Only 4 ports on a board may ring simultaneously. A 5th incoming call will cause an inline error from the board.

Aux Data 40975: the terminal equipment was on-hook when ring-tip was detected during ringing. This usually indicates a failure in the terminal equipment or the type of terminal has a low ringer impedance. Call the terminal equipment and verify that the terminal rings. If the terminal doesn't ring, replace it. Otherwise, enter **test port location**, and follow the procedure for [ONS Ringer Application Test \(#48\)](#).

Aux Data 40977: no terminal equipment was connected when ringing was attempted. Run **test port location**, and follow the procedure for the results of [ONS Ringer Application Test \(#48\)](#).

- c. **Error Type 15:** software audit error, does not indicate any hardware malfunction. Run the short test sequence, and investigate errors (if any).
- d. **Error Type 130:** the circuit pack was removed or has been insane for more than 11 minutes. To clear the error, reinsert or replace the circuit pack.
- e. **Error Type 257:** Associated Test #48 may cause some terminal equipment to ring briefly during daily maintenance. If this ringing is disturbing the customer or the terminal equipment, it should be disabled via **change station extension**. However, on some releases of the software, this will disable Tests #6, 47, and 35 as well as Test #48.
- f. **Error Type 769:** Associated Test #47 may cause a false alarm when the port is connected to off-premises equipment, some non-voice terminal equipment, and some loop equipment. If this causes a false alarm, use **change station**, and change the **Tests** field to **n** to disable the test.
- g. **Error Types 1281 and 1793:** See [XXX-BD \(Common Port Circuit Pack/Media Module\)](#).

Demand test descriptions and error codes

Investigate tests in the order presented. By clearing errors associated with the first test, errors generated from other tests may also be cleared. Click on the link to see the full description of the test, error codes, and recommended actions.

-BD (Announcement circuit pack)

MO Name in Log	Alarm Level	Initial command to run	Full name of MO
-BD	MIN WRN	<code>test board location 1</code>	Announcement Circuit Pack

Note:

The information contained in -BD refers only to the TN750-series of circuit packs. Expressions such as "announcement circuit pack" and "announcement board" are to be interpreted to mean the TN750-series only.

The TN750 announcement circuit pack is a service circuit which provides an integrated means for recording announcements that can be played back on demand by call processing as part of a calling feature (for example, announcements on hunt group calls). There are 16 Announcement Ports on the announcement circuit pack. Each port can play any integrated announcement, independently of the other ports. In addition to the 16 announcement Ports, the announcement circuit pack also has one Data Line Circuit Port (port 17). The Data Line Circuit Port is used for uploading/downloading the announcement memory to/from the memory card. If there are any errors associated with port 17, refer to [DAT-LINE \(Data Line Port\)](#). If there are any errors associated with any other port, refer to [-PT \(Announcement Port\)](#).

Note:

TN750C is required if the system has multiple TN750x announcement boards (up to ten are allowed). Only one TN750A/B may be present in the system with up to nine additional TN750C boards. All ten boards may be TN750C. The announcements from a TN750A/B can be saved and restored to a TN750C, but once the announcements are recorded onto a TN750C they are not backward compatible with the TN750A/B.

The announcement circuit pack has two processors on it. The first processor, or Angel, controls the circuit pack and communicates with the switch via the control channel on the TDM Bus. The second processor, or Speech Processor (SP), controls the speech memory and announcements. Digital speech is converted from its TDM Bus form to an internal storage form (for recording) and vice versa (for playbacks) by the 140AY device on the circuit pack, which has 16 channels (one for each Announcement Port).

General notes

Here are a few important general notes that apply to any problem on the announcement circuit pack. Read this before attempting to work on the TN750 announcement circuit pack or announcement Ports, especially if the circuit pack needs to be replaced.

1. The TN750 announcement circuit pack retains all integrated announcements *as long as the circuit pack has power*. For this reason, whenever there is a problem with either the announcement circuit pack or an announcement Port that may require the circuit pack to be reset, it is always best to try to reset the circuit pack with **reset board location** first. If that does not work, replace the circuit pack. Announcements are preserved through a software reset, but they are lost when the circuit pack is reseated.
2. If a customer has announcements on the announcement circuit pack, then announcements must be saved on the memory card to ensure that they are not lost. This should be done as soon as the announcements are recorded on the circuit pack (or whenever they are changed), assuming that the circuit pack is in proper working order (see Note).

Note:

Unlike translations, announcements are NEVER automatically saved to the memory card.

3. **Save announcements** replaces the TN750x announcement file on the memory card. Care must be taken not to mistakenly enter this command and, as a result, destroy a valid file on the memory card.
4. **Restore announcements** replaces the TN750x announcement circuit pack speech memory with the announcement file on the memory card. Care must be taken not to mistakenly enter this command, destroying valid speech memory, especially if the memory card does not have a valid announcement file on it.
5. Whenever the TN750x announcement circuit pack is replaced, announcements must always be rerecorded or downloaded to the new circuit pack. Otherwise, call processing is not able to use the pack.
6. If announcement speech memory is corrupted, announcements should not be saved [that is, if the Announcement Checksum Test (#209) fails, or if the speech sounds corrupted on playback]. This can ruin a good announcement file on the memory card and potentially cause errors/alarms on any circuit pack to which the new file is downloaded. However, if the customer does not have a valid announcement file on the memory card, announcements can be saved in an effort to try to retain some of them (all of the announcements recorded may not be corrupted).
7. Due to a hardware fault in the TN750 announcement board, the following sequence of events may cause the announcement file to become corrupted and unusable:
 - a. Fill the board with recorded announcements.
 - b. Delete the last few announcements recorded.

- c. Re-record the announcements deleted.

If the announcement file becomes corrupted, the only solution is to re-record all announcements. To do this, follow these steps:

- d. Remove the announcement board.
- e. Remove the tape cartridge from the tape drive. Do this so that announcements are not automatically restored from tape.
- f. Re-insert the announcement board.
- g. Re-record all announcements.
- h. Insert the tape cartridge in the tape drive.
- i. Enter **save announcements** to save all the announcements on the tape.

This hardware fault is fixed in the TN750B announcement board. However, the TN750B board will not automatically correct an announcement file which has previously been corrupted by a TN750 board. The only way to correct an announcement file corrupted by the TN750 board is to follow the steps above.

Announcement administration

A brief description of the integrated announcement administration is given here to aid in troubleshooting the announcement circuit pack and its ports. In many cases, it is necessary to record, play back, and/or delete announcements to resolve an alarm. It may also be necessary to save and restore announcements as part of the maintenance procedures. For a complete description of integrated announcement administration, please refer to *Administering Avaya Aura™ Communication Manager*.

Announcement session

Announcements can be recorded, played back, and deleted from an announcement session. A station's COS needs to include console permissions in order for that station to be able to enter an announcement session.

To enter an announcement session, go off-hook on a station that has console permissions and enter the appropriate Feature Access Code (FAC), administered as announcement access code on the FACs form. Dial tone should be returned at this point. Enter the extension of the announcement that needs to be recorded, deleted, or played back. Again, dial tone should be heard. To record an announcement, press station keypad digit **1**, record after the tone, and hang up when done. To play back an announcement, press **2**. To delete an announcement, press **3** (confirmation tone is given if the delete worked). Announcements can also be played back by simply calling the announcement extension associated with them.

Uploading/Downloading Announcements

Integrated announcements on the TN750 announcement circuit pack can be uploaded to the memory card with **save announcements**. Likewise, integrated announcements can be downloaded to the announcement circuit pack with **restore announcements**. Both of these commands require a free data module of NETCON type to be administered, a data module of announcement type (on the announcement circuit pack) to be administered, and a memory card. These commands are useful in maintaining the customer's recorded announcements. Depending on system traffic, announcement uploads and/or downloads take between 30 and 45 minutes.

The system automatically tries to download the announcement circuit pack five minutes after it is inserted. This automatic download procedure is aborted if:

- 1 An announcement is recorded within 10 minutes of circuit pack insertion.
- 1 An announcement download is invoked sooner with the **restore announcements**.
- 1 No announcement and/or NETCON data module is administered.
- 1 Either the announcement data module is busy or all the administered NETCON data modules are busy.
- 1 No memory card is in the system.
- 1 The memory card in the system does not have a valid announcement file saved on it.

Note:

Unlike translations, there is no provision in the system for automatically saving announcements to the memory card.

Announcement Board Locked Condition

The announcement circuit pack can exhibit a condition that does not allow recording.

If the circuit pack gets locked into this state (this is an extremely rare condition), two of the announcement ports on the circuit pack (one of which is the record port) will be unusable by software. Also, **save/restore announcements** will not work since the record port looks busy to the circuit pack. Note that software does not have any way of knowing this and will attempt to use the ports.

If the circuit pack is locked into this state, the following symptoms will be observed:

1. When attempting to record an announcement, users will hear the proper record tone, but the announcement will not record (they will not know it until the announcement is played back).
2. Performing a **test board long** when the circuit pack is in this state will yield the following abort codes:

- 1 Ports 1 AND 9 abort Test 206 with code 1024.
 - 1 Ports 1 AND 9 abort Test 205 with code 2000.
 - 1 Board-level Tests 209 and 210 abort with code 1024.
3. The **save/restore announcements** times out with:

Error encountered, can't complete request

The announcement circuit pack lock-up can be cleared remotely by performing a soft reset to the circuit pack:

- 1 **busyout board location** (this command drops every call in progress on the announcement circuit pack).
- 1 Reset the circuit pack using **reset board location**.
- 1 Release the board using **release board location**.

Error log entries and recommended actions

Table 21: -BD Error Log Entries 1 of 2

Error Type	Aux Data	Associated test	Alarm Level (See WRN message)	On/off Board	Recommended action
0 (a)	0	Any	Any	Any	test board location
1 (b)	0	Circuit pack removed or SAKI Test failed (#53)	MIN	ON	
2 (c)		None			
14 (d)	1 to 64	announcement Checksum (#209)

	17676	inline Error			
2817 (m)		Announcement Checksum (#209)	MIN	ON	test board location r 3
	17682	inline Error			
	17699	inline Error			
3840 (j)	Any	None			
3999 (o)	Any	None			
					2 of 2

All -BD alarms are upgraded to MAJOR when the BASE Tone Generator is set to 12 (France).

Notes:

- a. **Error Type 0:** Run the short test sequence first. If all tests pass, run the long test sequence. Refer to the appropriate test description and follow the recommended procedures.
- b. **Error Type 1:** the circuit pack totally stopped functioning or it was physically removed from the system.

If the circuit pack is not in the system, insert a circuit pack in the same slot as the error indicates to resolve this error. Or, if the circuit pack is in the system and the red LED is on, follow the instructions for Red (alarm) in the Circuit Pack LEDs section of *LED Descriptions for Avaya Aura™ Communication Manager Hardware Components (03-602804)*.

Note:

The alarm is logged about 11 minutes after the circuit pack has been removed and/or SAKI Test (#53) fails.

Reseating and/or replacing the circuit pack results in loss of integrated announcements (TN750/B only). See [General notes](#) near the beginning of this Maintenance procedure.

- c. **Error Type 2:** Check the Class of Restriction (COR) administered for the Data Line extension assigned to the TN750 for uploading and downloading announcements. The extension can be found by using `list data-module`.
- d. **Error Type 14:** logged when the announcement Checksum Test (#209) fails. The Aux Data indicates the number of the first defective announcement found. This number corresponds to the announcement numbers on the announcement form. The extension relating to the announcement can be determined by `display announcement`. This error only appears in the Error Log in conjunction with Error Type 2817. Follow the procedures for Error Type 2817 to troubleshoot Error Type 14.
- e. **Error Type 23:** the circuit pack has been logically administered but not physically installed. The alarm is cleared when the circuit pack is installed.
- f. **Error Type 125:** the wrong circuit pack is inserted in the slot where this circuit pack is logically administered. To resolve this problem, either remove the wrong circuit pack and insert the logically administered circuit pack OR use `change circuit-pack` to re-administer this slot to match the circuit pack inserted.
- g. **Error Type 217 and 267:** there is more than one TN750 announcement circuit pack inserted in the system. Remove the alarmed circuit pack.
- h. **Error Type 257:** transient communication problems with this circuit pack. This error is not service-affecting and no action is required.
- i. **Error Type 513:** if the Aux Data is in the range of 4352 - 4358, there is a hardware failure on the circuit pack. The circuit pack should be replaced.

Replacing the circuit pack results in loss of integrated announcements (TN750/B only). See [General notes](#) for more information.
- j. **Error Types 1025 and 3840:** not service-affecting, no action is required.
- k. **Error Type 1281:** the speech processor (SP) found one or more faults in the speech main memory (SMM). Whenever this error is logged, error 2817 is also logged [see Note (m)], which causes the announcement Checksum Test (#209) to run to determine if the bad memory location was being used by an announcement.
- l. **Error Type 1538:** the hyperactive circuit pack is out-of-service and may exhibit one or more of the following symptoms:
 - 1. The tests run on the ports of this circuit pack are returning with a NO-BOARD.
 - 2. A busyout/release of the circuit pack has no effect on test results.
 - 3. A `list configuration` command shows that the circuit pack and ports are properly installed.

Communication Manager Maintenance Object Repair Procedures

The system tries to restore the circuit pack within 15 minutes. If the error recurs after 15 minutes, replace the circuit pack. For more information, refer to *Maintenance Procedures for Avaya Aura™ Communication Manager, Media Gateways and Servers (03-300432)*.

- m. **Error Types 2049 and 2817:** logged in conjunction with Error Type 1281, Aux Data 17699. Because Error Type 1281 means that a defective speech memory location was found, [see Note (k)] the announcement checksum error is also logged. This causes the announcement Checksum Test (#209) to run, which determines if the defective memory location has corrupted any recorded announcements. If the Checksum Test passes, the faulty memory location is currently not being used, and the SP marks the location as faulty to ensure that future announcements do not attempt to use it.

Note:

As memory locations are marked faulty, the amount of available memory decreases, which decreases the total amount of announcement time available on the circuit pack.

- n. **Error Type 2049:** transient error that does not cause an alarm can occasionally occur during a TDM BUS or Tone Clock interchange. It is possible for a marginal Tone-Clock circuit pack to cause this error against the -BD without alarming the TONE-BD. If this error occurs again, replacing the Tone-Clock circuit pack may clear up this error. See the FAIL case in the [Clock Match Inquiry Test \(#212\)](#).
- o. **Error type 3999:** the circuit pack sent a large number of control channel messages to the switch within a short period of time. If Error Type 1538 is also present, then the circuit pack was taken out-of-service due to hyperactivity. If Error Type 1538 is not present, then the circuit pack has not been taken out-of-service, but it has generated 50% of the messages necessary to be considered hyperactive. This may be completely normal during heavy traffic periods. However, if this Error Type is logged when the circuit pack is being lightly used, it may indicate a problem with the circuit pack or the equipment attached to it.

Demand test descriptions and error codes

Investigate tests in the order presented. By clearing errors associated with the first test, errors generated from other tests may also be cleared. Click on the link to see the full description of the test, error codes, and recommended actions.

Order of investigation	Short Test Sequence	Long Test Sequence	D/ND ¹

NPE Audit Test (#50)		X	ND

1. D = Destructive, ND = Nondestructive

-PT (Announcement Port)

MO Name in Log	Alarm Level	Initial command to run	Full name of MO
-PT	MIN WRN	<code>test port location 1</code>	Announcement Port

The TN750 announcement circuit pack provides an integrated means for recording announcements that can be played back on demand by call processing as part of a calling feature (that is, announcements on hunt group calls). There are 16 Announcement Ports on the announcement circuit pack. Each port can play any integrated announcement, independently of the other ports. If there are any errors associated with the circuit pack, refer to [-BD \(Announcement circuit pack\)](#).

The announcement circuit pack has two processors on it. The first processor, or Angel, controls the circuit pack, and communicates with the switch via the control channel on the TDM Bus. The second processor, or SP, controls the speech memory and announcements. Digital speech is converted from its TDM Bus form to an internal storage form (for recording) and vice versa (for playbacks) by the 140AY device on the circuit pack, which has 16 channels, one for each Announcement Port.

See [-BD \(Announcement circuit pack\)](#) for general notes that apply to problems on the TN750 announcement circuit pack.

- 1 There is no memory card in the system.
- 1 The memory card in the system does not have a valid announcement file saved on it.

Note:

Unlike translations, there is no provision in the system for automatically saving announcements to the memory card.

Error log entries and recommended actions

Table 22: -PT Error Log Entries

Error Type	Aux Data	Associated test	Alarm Level	On/Off Board	Recommended action
0 (a)	0	Any	Any	Any	<i>test port location</i>

Notes:

- a. **Error Type 0:** Run the short test sequence first. If all tests pass, run the long test sequence. Refer to the appropriate test description and follow the recommended procedures.
- b. **Error Type 130:** the circuit pack has been removed or has been insane for more than 11 minutes. To clear the error, reinsert or replace the circuit pack.
- c. **Error Type 769** is logged and the port is alarmed when an alarm is raised on the announcement circuit pack because of a faulty condition with a common circuit pack resource. Any one of the following alarmed errors on the announcement circuit pack causes this error to be logged against the announcement Port: 1793, 2049, 2305, 2561. Follow the [-BD \(Announcement circuit pack\)](#) repair procedures to resolve these alarms. When the corresponding circuit pack alarm is cleared, this alarm clears.

Demand test descriptions and error codes

Investigate tests in the order presented. By clearing errors associated with the first test, errors generated from other tests may also be cleared. Click on the link to see the full description of the test, error codes, and recommended actions.

Order of investigation	Short test sequence	Long test sequence	D/ND ¹
Channel Administration Memory Array Test (#205)		X	ND
Playback Speech Memory Array Test (#206)	X	X	ND
140AY Channel Sanity Inquiry Test (#222)	X	X	ND

1. D = Destructive; ND = Nondestructive

ANNOUNCE (announcement)

MO Name in Log	Alarm Level	Initial command to run	Full name of MO
ANNOUNCE	none	none	ANNOUNCEMENT

The ANNOUNCE MO logs an error in the error log if `save announcements` or `restore announcements` does not complete successfully or if the system fails to restore announcements from the memory card at boot time.

Error Log Entries

Table 23: ANNOUNCE Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Recommended Action
1 (a) (d)	any	None			
257 (d)	any	None			
513 (b) (d)	0	None			
769 (d)	0	None			
1025 (c) (d)	any	None			

Notes:

- a. **Error Type 1:** occurred while saving announcements. See [Aux data error codes and recommended repair procedures](#).
- b. **Error Type 513:** User pressed cancel while announcements were being saved.
- c. **Error Type 1025:** Error occurred while restoring announcements. See [Aux data error codes and recommended repair procedures](#).
- d. **Error Types 1, 257, 513, 769, 1025:** The port field for this error contained the active PE complex when the error occurred.

Aux data error codes and recommended repair procedures

Table 24: Aux data error codes and recommended repair procedures 1 of 2

Aux data	Description/ Recommendation
32001	Internal system error. <ol style="list-style-type: none"> 1. Check other ANNOUNCE errors and take corrective action. 2. If there are no ANNOUNCE errors, retry the command at 2-minute intervals a maximum of 3 times. 3. If restore announcements fails, escalate the problem.
32002	Announcement circuit pack is in use. <ol style="list-style-type: none"> 1. Retry the command at 2-minute intervals a maximum of three times. 2. If restore announcements fails, escalate the problem.
32003	Announcement port is in use. <ol style="list-style-type: none"> 1. Wait for all announcement ports to become available. 2. Enter save/restore announcements.
32004	There are no announcements recorded on the announcement Circuit Pack. save announcements does not prevent the destroying of the announcement file on tape [286 systems] or on the memory card [386 systems].
32005	Integrated announcement circuit pack is not present. The Announcement Circuit Pack is not inserted, or it is defective. <ol style="list-style-type: none"> 1. Enter list config to check for the presence of the circuit pack in the system. 2. If the announcement Circuit Pack is present, use test board location to check the status of the announcement Circuit Pack.
32006	Announcement Data Module not available. <ol style="list-style-type: none"> 1. Enter status to check the status of the Announcement Data Module.
32007	Announcement Data Module out of service. <ol style="list-style-type: none"> 1. Enter status to check the status of the Announcement Data Module.
32008	Announcement data is being saved or loaded. <ol style="list-style-type: none"> 1. Retry the command at 2-minute intervals a maximum of three times. 2. If save/restore announcements fails, escalate the problem.
1 of 2	

Table 24: Aux data error codes and recommended repair procedures 2 of 2

Aux data	Description/ Recommendation
32012	Required Announcement Data Module is not administered. 1. Add an Announcement Data Module and repeat the command.
32015	Time of day not set. 1. Set the time of day, and reenter save/restore announcements .
32016	Internal system errors. Check for any other ANNOUNCE errors and take corrective action. If there are no other announcements errors, do the following: 1. Retry the command at 2-minute intervals a maximum of three times. 2. If save/restore announcements fails, escalate the problem.
2 of 2	

ASAI-ADJ (ASAI Adjunct)

The error log entries and recommended actions for ASAI-ADJ (ASAI Adjunct) are the same as the error log entries and recommended actions for BRI-SET, Various Adjuncts. For more information about specific ASAI-ADJ (ASAI Adjunct) error type, see the same error type on the BRI-SET/Adjunct Error Log Entries table in the [BRI-SET, Various Adjuncts](#) section.

ASAI-BD (Multi-Application Platform Board)

MO Name in Log	Alarm Level	Initial Command to Run	Full Name of MO
ASAI-BD	MIN WRN	<i>test board location</i>	ASAI-BD

Refer to [BRI-BD \(ISDN-BRI Line Circuit Pack\)](#) Maintenance documentation for circuit pack level errors. See also [ASAI-PT \(ASAI Port\)](#) and [ASAI-EPT \(ASAI Endpoint\)](#) for related line information. See the following exceptions listed below:

- 1 Hyperactivity: Currently, the common circuit pack is considered “hyperactive” if the circuit pack sends 200 uplink messages in a 10-second period. An alarm is issued when the limit reaches 400. When the limit reaches 500 uplink messages in 10 seconds, the board is taken out of service.
- 1 Port Administration: In Administration Without Hardware (AWOH), the switch allows administration of up to 8 ports in any of the first 12 ports. If the port type later reported by the board does not match the existing type, the switch assumes it to be a MAPD board with a different configuration and rejects the board.

ASAI-EPT (ASAI Endpoint)

MO Name in Log	Alarm Level	Initial Command to Run	Full Name of MO
ASAI-EPT	MAJ ¹	<code>test station extension</code>	ASAI-Adjunct

1. The alarm level for ASAI adjuncts is administered using **set options**. The alarm level can be set independently for on- and off-board alarms to WARNING, MINOR, or MAJOR for every ASAI adjunct in the system.

The TN800 is a PC-based platform that allows interaction of multiple applications with Communication Manager at any time. Communication Manager (native mode) supports emulation of three types of port MOs on this board. The type of ports to be emulated is defined by the applications running on the TN800.

Note:

If the TN800 is emulating BRI, the software/firmware supports up to 12 ports, but only 8 of the 12 ports can be administered at any one time.

Error log entries and recommended actions

Table 25: ASAI-EPT Error Log Entries 1 of 2

Error Type	Aux Data	Associated Test	Alarm Level ASAI-EPT	On/ Off Board	Recommended action
0 (a)	0	Any	Any	Any	<code>test ASAI-ADJ</code>
2 (b)	2-102	None

					2 of 2

1. Major alarms on this MO may be downgraded to Warning alarms based on the value used in **set options**.

Notes:

- a. **Error Type 0:** Run the short test sequence first. If every test passes, run the long test sequence. Refer to each appropriate test's description, and follow its recommended procedures.
- b. **Error Type 2:** ISDN-BRI signaling protocol violation. Timers associated with layer-3 messages expired before a required response was received. In the following table, the aux data column indicates which timer has just expired.

Aux Data	Timer Type
2	First T303 (SETUP timer)
3	Second T303 (SETUP timer)
4	T305 (DISConnect timer)
5	First T308 (RELease timer)
6	Second T308 (RELease timer)
10	T316 (REStart timer)
12	T309 (Layer-2 Failure timer)
16	TM100 (Management Information message Timer 1)
17	TM200 (Management Information message Timer 2)
102	TASAI (ASAI Routing Timer)

The switch sent a message to an endpoint that did not respond in the time allowed. This may be due to failure of the point-to-point signaling link or because of a problem in the ASAI adjunct. To repair, enter `test station extension` and perform the associated repair procedures for those tests.

Communication Manager Maintenance Object Repair Procedures

- c. **Error Type 257:** An endpoint is not responding to the service state query message sent to the adjunct or to the endpoint. This error causes an alarm to be raised. The alarm is retired when the switch receives a response to the service state query to the endpoint or to the adjunct.

When this error occurs for an ASAI adjunct, the Aux Data field indicates the state of the ASAI link and whether an invalid response or no response was received to the query from the switch, as shown in the following table:

Aux Data	ASAI Link State	Error
102	13-restarting	No response to RESTART message
104	13-restarting	Invalid response to RESTART message
152	13-restarted	No response to layer-3 query
154	13-restarted	Invalid response to layer-3 query
202	13-established	No response to layer-3 query
204	13-established	Invalid response to layer-3 query

See the section on maintenance SAT commands on Maintenance Commands for Avaya Aura™ Communication Manager, Media Gateways and Servers (03-300431) for an explanation of the ASAI link states.

For ASAI or Avaya adjuncts, the switch queries the adjunct every two minutes. The Layer 3 Query test is not executed for ASAI or Avaya adjuncts through a command entered from the management terminal. While alarmed for this error, the switch takes the associated port out-of-service for five seconds every 15 minutes. This action attempts to stimulate recovery actions to be taken by the adjunct.

When this error occurs for an ASAI or Avaya adjunct, the service technician should:

1. Execute `test station extension` and perform the associated repair procedures.
 2. Check the health of the adjunct by following the recommended repair procedures of the manufacturer of the adjunct if the preceding step does not resolve the problem.
- d. **Error Type 351:** logged against an ASAI endpoint when the adjunct asks the switch to suspend maintenance on the ASAI endpoint. Clear with busyout and release of the ASAI station.
- e. **Error Type 513:** the endpoint sent more messages than the switch could handle. The switch suspends the reception of messages from the endpoint for a short period of time. There is no repair procedure for this error. If the condition persists, replace the endpoint.
- f. **Error Type 769:** an ASAI endpoint's associated signaling link has too much traffic related to link establishment. This occurs when the signaling link is alternating between assigned and established states. If this problem persists, replace the endpoint.

- g. **Error Type 2562 - 2566:** the ASAI message is not transmitted because the transmit buffer for the ASAI link is full, causing the link to be flow-controlled. Frequent or persistent occurrence of these events may indicate a hardware problem or traffic overload on the signaling link or the ASAI adjunct. Follow the repair procedures issued by the manufacturer of the adjunct. If these attempts fail, re-engineering of the traffic on the signaling link or adjunct may be necessary.
- h. **Error Type 2567:** This version of ASAI is not supported. Check the software version that is running on the ASAI adjunct.
- i. **Error Type 2568:** The adjunct identification is invalid. Check the vendor ID or software running on the ASAI adjunct.
- j. **Error Type 3329:** the point-to-point signaling link to the endpoint went down, except when the link goes down because either a system technician has busied out the PKT-BUS, or it has failed. This error raises an alarm against the endpoint or adjunct. Execute `test station extension short` and note the results of the Signaling Link Status Test (#626). If this test fails, follow the repair procedure for [Signaling Link Status Test \(#626\)](#). The alarm is retired when the signaling link is re-established to the endpoint or adjunct.
- k. **Error Type 3584 - 3839:** The switch software logs certain ASAI cause values. The cause value is determined from the following formulas:
- If the Error Type is greater than 3712, the ASAI cause value is equal to the Error Type minus 3712. The switch sent this value to the adjunct.
 - If the Error Type is less than 3712, the ASAI cause value is equal to the Error Type minus 3584. The adjunct sent this value to the switch.
- [Table 26: ASAI cause values](#) contains a description of the various ASAI cause values and recommended system technician actions associated with the cause value.
- l. **Error Type 3841 - 4095:** The switch software logs certain ASAI cause values. The cause value is determined from the following formula:
- If the Error Type is greater than 3968, the ASAI cause value is equal to the Error Type minus 3968. The switch sent this value to the endpoint.
 - If the Error Type is less than 3968, the ASAI cause code is equal to the Error Type minus 3840. The endpoint sent this value to the switch.

Table 26: ASAI cause values 1 of 3

Code	Explanation	Recommendation
0	Unrecognized ASAI Protocol Operation.	<p>Requested ASAI protocol is not implemented by switch or adjunct. <i>Aux Data</i> field of error log entry contains protocol identifier for unrecognized operation.</p> <ol style="list-style-type: none"> 1. Consult switch and adjunct documentation to determine which set of operations is supported by switch and the adjunct. Turning off adjunct operations not implemented by the switch may resolve the problem.
34	No circuit or channel available	<p>A resource on the switch is unavailable for a call. For BRI endpoints, this cause value is not logged. For ASAI, this condition means that there are no available trunks for an outgoing call request.</p> <ol style="list-style-type: none"> 1. Verify that the adjunct is administered to support the trunk capabilities of the switch. 2. Investigate trunk-group status by entering status trunk from the SAT or by requesting trunk-group queries from the adjunct. 3. Perform trunk diagnostic procedures such as test trunk.
40	Resources not available.	<p>No available internal resources to service switch or adjunct request. Exceeds system transaction capacity for adjunct or switch.</p> <ol style="list-style-type: none"> 1. May require re-engineering of adjunct services.
1 of 3		

Table 26: ASAI cause values 2 of 3

Code	Explanation	Recommendation
50	Requested facility not subscribed	<p>Requested facility is implemented, but not administered. Potential administration problem with endpoint or adjunct.</p> <p>For BRI endpoints:</p> <ol style="list-style-type: none"> 1. Verify the switch administration of endpoint using display station or display data-module. 2. If step 1 does not resolve the problem, refer to the endpoint's service manual and verify administration on the endpoint. <p>For ASAI adjuncts:</p> <ol style="list-style-type: none"> 1. Display the Customer Optional Features screen (administration screen) on the switch to determine which ASAI capabilities are turned on in the switch. 2. Verify that the adjunct is administered to support the identical capabilities as the switch. If there is a mismatch in the administered capabilities, then re-administer the switch and/or the adjunct to establish a consistent set of desired capabilities on both the switch and the adjunct.
58	Bearer capability not currently available	<p>Requested bearer capability is implemented, but not administered. No B-Channel is administered. See code 50 above.</p>
63	Service or option not available	<p>Requested ASAI capability or resource is not available on the switch or adjunct. More than one adjunct may be contending for the same switch resource. Potential administration mismatch between the resource domains administered on the switch and those administered on the adjunct.</p> <ol style="list-style-type: none"> 1. Verify that no overlapping administration of switch resources (for example, requesting notifications on a single domain by multiple adjuncts attempting to control a single call) exists across any adjunct connected to the switch. If an overlap exists, then re-administer the adjuncts to ensure that each adjunct is associated with a unique set of switch resources.
65	Bearer service not implemented	<p>Requested service not implemented in switch or endpoint.</p>
2 of 3		

Table 26: ASAI cause values 3 of 3

Code	Explanation	Recommendation
69	Requested facility not implemented	Requested service not supported in switch or endpoint. 1. Consult switch and endpoint documentation to determine service support.
79	Service or option not implemented	Requested service or option (or combination of selected options) is not supported (implemented) in switch or the adjunct. 1. Consult switch and adjunct documentation to determine ASAI service and options supported by both switch and adjunct. Re-administration of the switch-administered capabilities (see Customer Optional Feature screen) or those of the adjunct may be necessary to correct the problem.
81	Invalid CRV	An invalid CRV was sent by the adjunct. 1. This may indicate a CRV inconsistency between the switch and the adjunct. See the CallVisor protocol reference manual.
87	Internal switch audit	There is an inconsistency in switch data records. 1. There is no action needed, since the switch has corrected the data inconsistency.
3 of 3		

Demand test descriptions and error codes

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND
Signaling Link Status Test (#626)	X	X	Nondestructive

ASAI-PT (ASAI Port)

MO Name in Log	Alarm Level	Initial Command to Run	Full Name of MO
ASAI-PT	MAJ ^{1,2} WRN	<code>test port location 1</code>	ASAI ISDN BRI port

1. The alarm level for ASAI adjunct ports may be administered using **set options**. The alarm level can be set independently for on- and off-board alarms to WARNING, MINOR, or MAJOR for every ASAI adjunct port in the system.
2. All alarming for an ASAI adjunct and off-board alarming for an ASAI port is disabled if the ASAI adjunct asks the switch to suspend maintenance. When this occurs, an error and a WARNING alarm is logged against the ASAI adjunct. Check the Hardware Error and Alarm Logs to see if the adjunct has disabled alarming.

Unless otherwise stated, every maintenance action contained in this section applies to ASAI-PT and ISDN-BRI ports connected to ASAI adjuncts. This port type is administered as an ASAI-BD on the TN800 circuit pack.

The TN800 circuit pack is a PC-based platform that allows interaction of multiple applications with Avaya™ Communication Manager. Communication Manager software (native mode) supports emulation of three types of port MOs on this board. The type of ports to be emulated are defined by the applications running on the TN800. The TN800 can support up to 32 ports (time slots) at a time.

The TN800 connects to the switch through a single slot in the backplane, however its width is not limited to one slot. The number of slots occupied by the TN800 is supplied by the board during its insertion. The TN800 (Release 5 and higher) is three slots wide. The blank (reserve) slots are to the left of the functional slot.

In non-native mode, the TN800 is recognized as TN556, TN2181, TN754, or TN746 based on the switch software and the application running on the TN800. In non-native mode only one type of port MO runs at any time, and the port type depends on the application running on the TN800. If the TN800 fails diagnostics in non-native mode, the system's alarm and error logs would show a failure for the board type the TN800 is emulating.

Error log entries and recommended actions

Table 27: ASAI-PT Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Recommended Action
0 (a)	0	Any	Any	Any	<code>test port location</code>
1 (b)	(a)	Level 1 Status Inquiry (#621)	MAJ ¹	OFF	<code>test port location r 2</code>
513 (c)	0	none	MAJ	ON	
1537 (d)	46210	CRC Error Counter (#623)	MAJ ₁	OFF	
3841 (e)	46208	None			
3844 (f)	46223	None			
3845 (g)	46211	None			
3846 (h)	TEI	None			

1. Major and Minor alarms may be downgraded to warning alarms based on the value used in **set options**.

Notes:

- a. **Error Type 0:** Run the short test sequence first. If every test passes, run the long test sequence. Refer to each appropriate test's description, and follow its recommended procedures.
- b. **Error Type 1:** Level 1 Status inquiry failed or the BRI circuit pack detected that Level 1 has been deactivated on the port. The `Aux Data` field contains one of the following values:

Blank	The Level 1 Status Inquiry failed.
32773	The ASAI-Line circuit pack detected Level 1 has been deactivated.

Refer to the repair procedures for [Level 1 Status Inquiry Test \(#621\)](#) If the alarm does not clear, verify the status of the PC/server. This could be a customer network issue and not a board problem.

- c. **Error Type 513:** The circuit pack is having problems transmitting data to the packet bus. This error occurs when the packet bus transmit FIFO buffer overflows and most likely indicates a hardware problem. Use troubleshooting procedures for both on-board hardware problems and potential off-board packet bus problems.

- d. **Error Type 1537:** The port received an invalid frame over the D-Channel. This error is most likely due to a problem with the wiring to the set or adjunct, interference on the wiring due to a noise source, or no termination (an open circuit). It usually does not indicate a problem with the circuit pack.
 - 1. Check the wiring to the endpoints or the adjunct.
 - 1. If the problem persists, replace the endpoints or adjuncts.
- e. **Error Type 3841:** a Layer 1 Transmission error is detected for the port. Run the long test sequence, and note the results of the [Layer 1 Transmission Error Counter Test \(#624\)](#).
- f. **Error Type 3844:** the circuit pack detects an overflow of its receive buffers. Run the long test sequence, and note the results of the [Receive FIFO Error Counter Test \(#625\)](#).
- g. **Error Type 3845:** the [BRI Port Local LAN Looparound Test \(#618\)](#) fails. Run the long test sequence, and note the results of Test #618.
- h. **Error Type 3846:** the TEI (Terminal Endpoint Identifier) administered for the ASAI endpoint most likely does not match the TEI administered in the ASAI adjunct. Check the switch administration of the TEI against that of the adjunct, and make sure that both are using the same TEI.

Demand test descriptions and error codes

Investigate tests in the order presented. By clearing errors associated with the first test, errors generated from other tests may also be cleared. Click on the link to see the full description of the test, error codes, and recommended actions.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND ¹
BRI Port Local LAN Looparound Test (#618)		X	D
Level 1 Status Inquiry Test (#621)	X	X	ND
CRC Error Counter Test (#623)		X	ND
Layer 1 Transmission Error Counter Test (#624)		X	ND
Receive FIFO Error Counter Test (#625)		X	ND
Clear Error Counters Test (#270)	X	X	ND

1. D = Destructive, ND = Nondestructive

ASAI-RES (TN800 reserve slot)

MO Name in Log	Alarm Level	Initial Command to Run	Full Name of MO
ASAI-RES	NONE	NONE	TN800 ASAI reserve slot
DIG-RES	NONE	NONE	TN800 DIG reserve slot

Error log entries and tests also apply to [DIG-RES \(TN800 reserve slot\)](#).

There are no tests associated with these MOs. Both the `test board` and `busyout board` commands abort when either is attempted on a reserved slot. An error message indicates the slot is associated with the circuit pack that the TN800 is emulating, but the requested operation is not valid.

The TN800 MAPD (Multi-Application Platform) circuit pack connects to the switch through a single slot in the backplane. The number of slots occupied by the MAPD pack is supplied by the board when inserted. The TN800 in R5EM is three slots wide. The TN800 requires 2 reserve slots to its left. The reserve (blank) slots are to left of the functional slot and are place holders on the switch, and do not have any interaction with the switch.

Each instance of these MOs represents a reserve slot associated with respective circuit pack mode in which the MAPD is working.

ATM-BCH (ATM B-Channel Trunk)

MO Name in Log	Alarm Level	Initial Command to Run	Full Name of MO
ATM-BCH	MAJ ¹ MIN	<code>test port location 1</code>	ATM B-Channel Trunk
	WRN	<code>test port location</code>	

1. A MAJOR alarm on a trunk means that alarms on these trunks are not downgraded by **set options**, and at least 75% of the trunks in this trunk group are alarmed.

ATM-BCH explains how to test and repair TN230x ATM Interface circuit packs (TN2305 and TN2306) that have ATM B-Channel trunks administered for ATM Circuit Emulation Service (CES).

For additional repair information, see also, [ATM-SGRP \(ATM Signaling Group\)](#) and [PKT-BUS \(Packet Bus\)](#).

For maintenance instructions for TN230x circuit packs that are administered as Expansion Interfaces for ATM network connectivity, see [ATM-INTF \(ATM Interface\)](#).

ATM Circuit Emulation Service

Under ATM Circuit Emulation Service, you simulate ISDN-PRI circuits by assigning ATM ports to signaling groups. Each signaling group represents a PRI circuit, and the ports in the group represent the D-Channel and B-Channels of that circuit. B-Channels must also be assigned to ISDN-PRI trunk groups. TN230x circuit packs support up to 248 ports per circuit pack.

Signaling Group Components

B (bearer) channels (ATM-BCH) transmit digitized voice or data, while a separate D-channel (ATM-DCH) handles call-control signaling. One D-channel handles signaling for a group of B-Channels that combine to form a signaling group (ATM-SGRP).

B-Channel Service States

The ISDN specification defines two service state categories for B-Channels as listed in [ATM ISDN service states](#).

Table 28: ATM ISDN service states

Category	Description		
Service states			
In-Service (INS)	B-Channel is in normal operating state	Active	A call is connected over the B-Channel.
		Idle	There is no call on the B channel.
Out-of-Service/ Far-End (OOS/FE)	The switch has not successfully negotiated B-Channel connection as of yet. Calls cot be placed or received. When you first administer a B-Channel, the switch initializes the B channel to this state while it tries to negotiate a connection to the far end. If the request times out with no response from the far end, the switch leaves the B-Channel in the OOS/FE state.		
Out-of-Service/ Near-End (OOS/NE)	The NPE Crosstalk test has failed, or the trunk is busied out. Calls cot be placed or received.		
Maintenance/ Far-End (MTC/FE)	A request has timed out with no response from the far end after signaling is in place and B-Channels are in service. Calls can be received but not placed, and stable calls are unaffected.		
Maintenance/ Near-End (MTC/NE)	The signaling channel ISDN-PLK has been busied out, possibly after <code>test trunk grp#/mem# long</code> . Calls cot be placed or received, but stable calls are unaffected.		
Pending states	The switch is waiting for a reply from the far end. Pending service states remain in effect until the near end receives a response or times out.		
Pending-in-Service	The near end is waiting for a response to a transition-to-service request.		
Pending-Maintenance	The near end is waiting for a transition-to-maintenance-service request (US and other country-protocol-1 systems).		

B-Channel Alarms

The Maintenance/Far-End and Out-Of-Service/Far-End states generate warning alarms displayed with `status trunk grp#/mem#`.

Table 29: ATM-BCH alarms by service state

Service state	Alarm ¹	Possible cause	Possible solution
Out-of-Service/NE	WRN	Trunk busied out	Release the port with <code>release trunk grp#/mem#</code> .
	MIN	NPE Crosstalk test (#6) failed	Replace ATM circuit pack.
	None	ATM circuit pack lost signal or there is a circuit pack problem.	Install circuit pack or cable. Check circuit pack using procedures in ATM-BCH. Check far-end switch status.
Out-of-Service/FE	WRN	Unadministered far end	Administer the corresponding trunk on the far-end switch.
	WRN	Far-end busied out	Check the status of the far-end switch.
Pending/ In-Service	None	Maintenance message timed out waiting for reply	Wait 2 minutes after the pending state clears, and check the service state.
Pending/Maint			
Maint/NE	None	ISDN test call in progress (<code>test trunk long</code>)	Wait for the test to finish and recheck.
	None	System link busied out	Check link status. Run <code>release link link#</code> .
Maint/FE	WRN	Signaling channel down for over 90 sec.	See ATM-SGRP (ATM Signaling Group) or ATM-DCH (ATM D-Channel Port) .
	WRN	Repeated lack of response to messages sent to the far end	Wait. Maintenance software resends messages periodically. Or run <code>test trunk grp#/mem#</code> or <code>test signaling-grp grp#</code> .
	WRN	The far-end trunk is being tested.	Check status of the far-end switch. Wait for testing to finish.
In-Service	None	Normal operating state	

1. ATM-BCH alarms. Alarms against other MOs may also be present.

Error log entries and recommended actions

Table 30: ATM-BCH Error Log entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Recommended Action
0 (a)	0	Any	Any	Any	<i>test port location</i>
1(b)	Any				<i>test port location</i>
18	0	<i>busyout trunk grp/mbr</i>			<i>release trunk grp/mbr</i>
129 (c)			WRN	OFF	<i>test port location</i>
130 (d)					<i>test port location</i>
257(e)	Any	Service State Audit Test (#256)			<i>test port location</i>
513(f)	Any		WRN	OFF	<i>test port location</i>
769(g)	Any	Service State Audit Test (#256)			<i>test port location</i>
1793 (h)	Any				<i>test port location</i>
3073(i)	Any	Service State Audit Test (#256)			<i>test port location</i>
3585(j)	Any				none
3841 (k)	Any		WRN	OFF	none

Notes:

- a. **Error Type 0:** Run the short test sequence first. If every test passes, run the long test sequence. Refer to each appropriate test’s description, and follow its recommended procedures.
- b. **Error Type 1:** the two ends of the ATM trunk do not agree on the ISDN call state. Possible causes:
 - 1 Received a DISConnect or RELease COMplete message with cause value 52 (outgoing calls barred)
 - 1 Received a DISConnect or RELease COMplete message with cause value 54 (incoming calls barred)

- 1. Outgoing call renegotiated by the far end to another B-Channel in the absence of SETUP message glare
- 1. Near end attempted a call on a B-Channel that the far end has marked OOS

When running the short test sequence, note the results of the [Call State Audit Test \(#257\)](#).

- c. **Error Type 129:** the far-end switch changed its ISDN service state to either out-of-service or maintenance. This may be a temporary condition because the far end is testing that trunk or a hardware problem with the trunk. Outgoing calls may not be allowed over that trunk.
 - 1. Investigate the trunk's status (`status trunk grp#/mem#`).
- d. **Error Type 130:** the circuit pack has been removed or has been insane for more than 11 minutes. Reinsert or replace the circuit pack to clear the error.
- e. **Error Type 257:** SETUP received for a B-Channel that is in an invalid service state. Service states may be incompatible at the two ends of the trunk. A normal call was received while the B-Channel was MTC/FE, MTC/NE, OOS/FE, or OOS/NE or a test call was received while the B channel was OOS/FE or OOS/NE.
- f. **Error Type 513:** RELease COMplete message received with cause value 82 (nonexistent channel). The B-Channel may not be administered at the far end. The trunk has been placed in the OOS/FE state.
- g. **Error Type 769:** inconsistent SERvice or SERvice ACKnowledge message. Possible causes:
 - 1. SERvice or SERvice ACKnowledge message received containing a change status that is more available than the previously-transmitted SERvice message.
 - 1. Unsolicited SERvice ACKnowledge message received containing a change status that does not match the current B-Channel state.

ISDN-PRI service-state negotiation rules have been violated and may indicate that a pending service-state audit is failing. The system:

- 1. cancels the maintenance timer
- 1. increments the Service State Audit counter
- 1. attempts a Service State Audit

When running the short test sequence, note the results of the [Service State Audit Test \(#256\)](#).

- h. **Error Type 1793:** TN230x circuit pack failed. The maintenance system
 - 1. places the trunk in the OOS/NE state
 - 1. sends a SERvice message to the far end (if possible) containing a change status of OOS for the B-Channel
 - 1. returns the trunk to service when the ATM trunk circuit pack reports the failure cleared
- i. **Error Type 3073:** Service State Audit attempt failed. See [Service State Audit Test \(#256\)](#). Calls can be received but not placed until the test passes and the trunk state returns to In-Service. Check the trunk's status with `status trunk grp#/mem#`.

Communication Manager Maintenance Object Repair Procedures

j. **Error Type 3585:** ISDN RESTART message received. Active calls have been dropped.

The following Aux Data values (Error Type 3585 only) below represent the trunk's ISDN call state at the time Error 3585 occurred. This information can be useful if users report dropped calls on the ISDN-PRI trunks.

Aux Data	Description
0	An idle trunk received a restart.
10	An ISDN RESTART from the far end has unexpectedly cleared a call in the ACTIVE state (call stable, parties talking).
4 7 8 260 263	An ISDN RESTART from the far end has unexpectedly cleared a RINGING call.
1 3 6 9 265	An ISDN RESTART from the far end has unexpectedly cleared a call before the call entered the RINGING state.
11 12 19 531 267 268	An ISDN RESTART from the far end has unexpectedly cleared a call that was already in the process of clearing. If this condition occurs frequently, the far end may be trying to clear trunks that appear to be in the "hung" state.

k. **Error Type 3841:** the far end rejected an ATM CES trunk selected by the near end 10 times. The ATM CES trunk may not be administered on the far end.

1. Get the physical name of the ATM trunk by noting the decimal number in the `Aux Data` field.
2. Check administration for the named trunk on the far end.
3. If problems persist, then busyout the ATM trunk to take it out of the hunt group.

The WARNING alarm retires automatically whenever a called endpoint answers an outgoing or incoming call that uses the alarmed trunk.

Demand test descriptions and error codes

Investigate tests in the order presented. By clearing errors associated with the first test, errors generated from other tests may also be cleared. Click on the link to see the full description of the test, error codes, and recommended actions.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND ¹
Signaling Link State Audit Test (#255)	X	X	ND
Service State Audit Test (#256)	X	X	ND
Call State Audit Test (#257)	X	X	ND
ISDN Test Call Test (#258)		X	ND

ATM-DCH (ATM D-Channel Port)

MO Name in Log	Alarm Level	Initial Command to Run	Full Name of MO
ATM-DCH	MIN	<code>test port location 1</code>	ATM D-Channel
	WRN	<code>test port location</code>	

Note:

TN2305 and TN2306 circuit packs are not interchangeable. Always replace an ATM circuit pack with the same type.

ATM-DCH uses the existing ISDN-PLK or D-channel maintenance strategy with modifications. The ATM circuit pack can be administered for up to 8 Circuit Emulation Service (CES) or signaling groups, each with its own D-Channel, as opposed to one D-Channel for an entire DS1 circuit pack.

Note:

Due to the dual personalities and the number of D-Channels that the ATM board can possess, the inline errors and signaling port LAN loopback test have been moved to [ATM-TRK \(Circuit Emulation Service Circuit Pack\)](#). When an inline error is sent due to packet bus errors, the ATM circuit pack receives the error, not ATM-DCH.

The D-channel ISDN-PRI interface is emulated for ATM-CES and uses out-of-band signaling to transmit control messages between two endpoints. User information or bearer channels (B-Channels) carry digitized voice and digital data and are assigned to DS1 ISDN trunks or PRI endpoints. Call-control signaling for the B-Channels is combined and carried over the separate ISDN-PRI Signaling Link port D-Channel.

Problems with ATM-DCH affects every associated B-Channel, since call-control signaling can't reach the far-end switch or terminal adapter. Stable calls can remain operational, but no new calls can be made. In turn, ATM-DCH depends on the:

- 1 TN230X ATM Trunk circuit pack where it resides
- 1 Packet bus that provides the link to the processor

When working ATM-DCH alarms or errors, also investigate

- 1 [ATM-TRK \(Circuit Emulation Service Circuit Pack\)](#)
- 1 [PKT-BUS \(Packet Bus\)](#)

Error log entries and recommended actions

Table 31: ATM-DCH Error Log entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Recommended Action
0 (a)	0	Any	Any	Any	<i>test port location</i>
18 (b)	0	<i>busyout port location</i>	WRN	OFF	<i>release port location</i>
130 (c)			WRN	ON	<i>test port location</i>
1793 (d)		Signaling Link Board check (#643)			<i>test board location 1</i>

Notes:

- a. **Error Type 0:** Run the short test sequence first. If every test passes, run the long test sequence. Refer to each appropriate test's description, and follow its recommended procedures.
- b. **Error Type 18:** D-Channel busied out. No calls possible over this D-Channel.
- c. **Error Type 130:** circuit pack removed or has been insane for more than 11 minutes. To clear the error, reinsert or replace the circuit pack.
- d. **Error Type 1793:** ATM Trunk circuit pack failed the Signaling Link Board check (#643). Resolve any [ATM-TRK \(Circuit Emulation Service Circuit Pack\)](#) errors in the Error Log.

Demand test descriptions and error codes

The command to test the ATM-DCH MO is *test port location*, where *location* is port number 9-32.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND
Signaling Link Board Check (#643)	X	X	Nondestructive

ATM-EI (Expansion Interface Circuit Pack)

MO Name in Log	Alarm Level	Initial Command to Run	Full Name of MO
ATM-EI	MAJ MIN WRN	<code>test board location</code>	ATM Expansion Interface circuit pack

ATM-EI covers the ATM circuit pack administered as an Expansion Interface (ATM-EI) for ATM Port-Network Connectivity (ATM PNC). The ATM-EI monitors port network connectivity between a server and every PN through the ATM switch.

The circuit packs listed in [Table 32: ATM-EI circuit packs](#) are ATM-EI boards if they are administered to support ATM Port Network Connectivity (ATM PNC).

Table 32: ATM-EI circuit packs

Circuit pack	Fiber	Echo cancellation
TN2305	Multimode	Y
TN2306	Single mode	Y

Note:

TN230x circuit packs are not interchangeable. Always replace an ATM circuit pack with the same type.

Note:

ATM switch maintenance is not covered in this section. When maintenance software suspects the ATM switch connections, it raises appropriate Communication Manager alarms. To clear any ATM switch faults, refer to the particular ATM switch's documentation.

LEDs

The ATM Interface circuit pack has three LEDs:

- 1 Red indicates some alarm condition.
- 1 Green indicates maintenance testing in progress.
- 1 Amber provides useful visual information regarding the operating mode of the ATM-EI and possible error conditions.

The possible LED states are described in [Table 33: ATM Interface LED codes](#).

Table 33: ATM Interface LED codes

LED	LED Status	Condition
Red	Steady on	Board is not healthy
	Not on	Normal conditions
Red and Green	Red LED solid on Green LED 200 msec on; 200 msec off	Board is in the processes of booting
Green	Steady on ¹	Maintenance is running tests on the board
	100 msec on - 100 msec off	No links to the board
Amber	100 msec on -100 msec off	Board has loss of signal alarms - Fiber Loss of Signal (LOS), LOF, MS_RDI, MS_AIS, LCD, HP_RDI, HP_AIS, LOP, PSC
Amber	500 msec on; 500 msec off	Signal to the ATM switch is down
Amber	2 sec on; 0.2 sec off	ATM-EI is Expansion Archangel (EAA)
Amber	Steady on	ATM-EI active (Center Stage Switch PN)
Amber	Not on	ATM-EI standby

1. The green LED flashes between tests.

ATM-EI-Related Commands

The following commands can be helpful in resolving ATM-EI problems:

<code>add atm pnc</code>	<code>list measurements atm</code>
<code>busyout/release atm pnc</code>	<code>remove atm pnc</code>
<code>busyout/release board</code>	<code>reset board</code>
<code>change atm pnc (pnc duplication)</code>	<code>status atm pnc</code>
<code>display atm pnc</code>	<code>status cabinet</code>
<code>list atm oam-statistics</code>	<code>status port-network</code>
<code>list atm pnc</code>	<code>test board</code>

Replacing an ATM-EI Circuit Pack

Standard Reliability

1. Enter `busyout atm pn#` (this is service-affecting) on the SAT.
2. Replace the ATM PNC circuit pack, and reconnect the fiber.
3. Enter `release atm pnc`.
4. Wait 2½ minutes for board insertion.
5. Enter `list sys-link` to verify that the links are up.
6. Enter `test board location`, and verify that every test passes.

Duplex or High Reliability

There is 1 ATM-EI circuit pack in each PN.

1. Enter `busyout atm pnc #` on the SAT.

Note:

If the ATM-EI is in a PN, this is service-affecting.

2. Replace the circuit pack.
3. Enter `release atm pnc`.
4. Wait 2½ minutes for board insertion.
5. Enter `list sys-link` to verify that the links are up.

6. Enter `test board location`, and verify that every test passes.

Critical Reliability

There are 2 ATM-EI circuit packs in each PN.

1. Enter `status pnc` on the SAT. If the board is on the active side, enter `reset pnc interchange` to switch the active ATM-EI board to the standby side.
2. Enter `busyout pnc-standby`.
3. Enter `busyout atm pnc # a-pnc` or `b-pnc`.
4. Replace the circuit pack.
5. Enter `release atm pnc #`.
6. Enter `release pnc-standby`.
7. Wait 2½ minutes for board insertion.
8. Enter `test board location`, and verify that every test passes.

Basic ATM PNC Administration

Note:

This section contains basic administration information only. Refer to *ATM Installation, Upgrades, and Administration using Avaya Communication Manager*, for more detailed information.

ATM PNC connections involve administering

- 1 1 ATM-EI board in each PN (standard, duplex, or high reliability)
- 1 2 ATM-EI boards in each PN (critical reliability)

Adding ATM PNC Connections

Standard, Duplex or High Reliability

1. If the ATM-EI circuit pack is absent or if the circuit pack is present but in a PN, use the `change circuit-pack` command to add circuit pack translations.
2. Enter `add atm pnc n` (connection number), and administer the circuit pack's location and its ATM address.

Critical Reliability

1. Enter `change system-parameters duplication`, and change the **Enable Operation of PNC Duplication** field to `n`.

Communication Manager Maintenance Object Repair Procedures

2. If the ATM-EI circuit pack is absent or is present but in a PN that does not yet have PNC connectivity to it, use the **change circuit-pack** command to add circuit pack translation for the missing circuit pack.
3. Enter **add atm pnc n** (connection number), and administer the circuit pack location and ATM address.
4. Enter **change system-parameters duplication**, and change the **Enable Operation of PNC Duplication** field to **y**.

Removing ATM PNC Connections

Standard, Duplex or High Reliability

Note:

These systems are *not* equipped with PNC duplication.

1. Enter **busyout atm pnc n** (connection number).
2. Enter **remove atm pnc n** (connection number).

Critical Reliability

1. Enter **status pnc**, and ensure that the A-PNC is active.
If not, request a PNC interchange using the **reset pnc interchange** command.
2. Enter **busyout pnc-standby**.
3. Enter **change system-parameters duplication**, and change the **Enable Operation of PNC Duplication** field to **n**.
4. Enter **busyout atm pnc n** (PN's number).
5. Enter **remove atm pnc n** (PN's number) to remove both ATM-EI boards, or enter **change atm pnc** to remove the B-side ATM-EI board.
6. Enter **change system-parameters duplication**, and change the **Enable Operation of PNC Duplication** field to **y**.

Changing Circuit Pack Location or ATM Address

Standard, Duplex or High Reliability

Note:

These systems are *not* equipped with PNC duplication.

1. Remove the ATM PNC connection. See [Removing ATM PNC Connections](#).
2. Add an ATM PNC connection. See [Adding ATM PNC Connections](#).

A-side ATM-EI—Critical Reliability

1. Remove the ATM PNC connection. See [Removing ATM PNC Connections](#).
2. Add an ATM PNC connection. See [Adding ATM PNC Connections](#).

B-side ATM-EI—Critical Reliability

1. Enter `status pnc`, and ensure that the A-PNC is active.
If not, request a pnc interchange using `reset pnc interchange`.
2. Enter `busyout pnc-standby`.
3. Enter `list config carrier`, and verify that an ATM circuit pack is assigned for the new location. If not, add the ATM circuit pack's translations.
4. Enter `busyout atm pnc n` (connection number) `b-pnc`.
5. Enter `change atm pnc n` (connection number) and change circuit pack location for the B side.
6. Enter `release pnc-standby`.

Changing ATM Address of Standby ATM PNC EI, Critical Reliability

1. Enter `busy pnc-standby`.
2. Enter `change atm pnc n` (connection number), and change the ATM address for the standby side.
3. Enter `release pnc-standby`.

3842(w)					
3843 (x)					
3999 (y)	Any				
Any (z)	32767				
					3 of 3

Notes:

- a. **Error Type 0:** Run the short test sequence first. If every test passes, run the long test sequence. Refer to each appropriate test's description, and follow its recommended procedures.
- b. **Error Type 2:** The on-board DUART chip failed. This results in communication failure between the PN's Maintenance board and the ATM-EI board. The Maintenance board should have a red LED lit because the link to the ATM-EI is down in this PN.
 1. Reset the board with *reset board location*.
 2. If the board does not recover, replace the board.
- c. **Error Type 18:** The ATM-EI circuit pack has been busied out.
 1. Release the circuit pack (*release board location*).
- d. **Error Type 23:** An ATM-EI circuit pack has been administered with the `add atm pnc n` command, but the circuit pack has not been physically inserted into the system.
 1. Insert an ATM-EI circuit pack at this location.
- e. **Error Type 125:** A wrong circuit pack is located in the slot where the ATM-EI circuit pack is logically administered.
 1. Either remove the wrong circuit pack and insert the ATM-EI circuit pack or remove the ATM-EI administration. See [Basic ATM PNC Administration](#).

Communication Manager Maintenance Object Repair Procedures

2. Remove the ATM-INTF administration and re-administer the slot (change circuit-pack) to match the circuit-pack that is physically present in this slot.

f. **Error Type 131:** An ATM-EI circuit pack has been removed from the slot for 5 minutes.

1. Insert the ATM-EI circuit pack into its administered slot.
2. Another way to resolve or prevent this alarm is to remove the ATM-EI administration. See [Basic ATM PNC Administration](#), then remove the ATM-INTF administration (change circuit-pack).

It is possible that the ATM-EI could be held in reset by the PN's Maintenance board and is not inserted in the system.

3. Try `test maint P long` on the maintenance board in the same PN.

g. **Error Type 257:** [Expansion Interface Control Channel Test \(#316\)](#) failed (board cot communicate on the TDM bus control channel). Follow the suggested test procedures.

Error Type 258: The archangel is out of sequence (Aux Data indicates Angel number).

Error type 259: The expansion archangel link (EAL) to the active ATM-EI board is down. See [SYS-LINK \(System Links\)](#).

h. **Error Type 513:** The ATM Crosstalk test failed. The board is either writing to or reading from a TDM time slot that is not allocated to the board.

1. Test the board (`test board location`), and follow the procedures suggested for this test. In random tests of a single DSP during low or high traffic, the same DSP can be tested more than once.

i. **Error Types 769 and 770:** are board-degraded alarm errors that result when the ATM switch is sending corrupted cells or excessive AAL/LAPD retransmissions (off-board ATM cell corruption errors). These errors indicate the detection of a problem in handling ATM cells that are received from the fiber interface.

Aux Data for these Error Types:

Error Type	Aux Data	Description
769	34	Excessive AAL-5 retransmission requests
769	35	Excessive LAPD retransmission requests
770	25	Uncorrectable ATM cell headers – threshold
771	26	VPI, VCI pair unknown

The problem is most likely *not* on the ATM-EI circuit pack reporting the errors, but it could be due to one or more of the following reasons:

1. The fiber is not snugly connected to either the board or the ATM switch.
1. The PN's packet bus is corrupting the cells. See [PKT-BUS \(Packet Bus\)](#) (Aux Data 35 only).

- 1 The fiber between the ATM switch and the ATM-EI is too long (greater than 2 km for multimode fiber). Use loopback to see if the fiber is corrupting the cells.
- 1 Some other ATM-EI board is not receiving the cells properly.
- 1 The intervening ATM switch is dropping the ATM cells due to a shortage of bandwidth, or the server is using more than the subscribed bandwidth.

Error Type 771: The ATM switch is sending cells with unknown VPI and VCI address (wrong connection).

- 1. Ensure that the address translations are correct.

j. **Error Types 1024-1151:** These errors represent problems detected by the ATM-EI board in response to SETUP and ADDPARTY requests from software.

- 1 The Error Types and descriptions are in [Table 35: ATM Error Types 1024 - 1151](#).
- 1 Aux Data values represent PN and Angel numbers and are in [Table 36: Error Type 1024-1151 Converted Aux Data Values](#).

Table 35: ATM Error Types 1024 - 1151 1 of 3

Error Type	Description	General problem
1024	Next node unreachable	ATM protocol stack on ATM-EI3 circuit pack
1056	DTL Transit not my node ID	
1 of 3		

Table 35: ATM Error Types 1024 - 1151 2 of 3

Error Type	Description	General problem
1088 1104	ATM-EI circuit pack received a request with an invalid connection identifier.	Firmware-detected problems on the ATM-EI circuit pack. Note: Error Types 1088–1103 are reported by the board that is originating the connection. Error Types 1104–1119 are reported by the board that is terminating the connection. In most cases, when the terminating board reports one of these errors, the originating board also reports an ATM-NTWK error for the same event (usually with Error Type 21).
1089 1105	ATM-EI circuit pack received a request with a reference to an unknown VC token.	
1090 1106	ATM-EI circuit pack did not have enough resources (memory) for the requested operation.	
1091 1107	Internal failure in the local protocol stack. This can occur when the connection to the ATM switch failed, perhaps because the: <ul style="list-style-type: none"> 1 ATM switch rebooted 1 fiber between the ATM switch and the ATM-EI circuit pack disconnected 	
1092 1108	ATM-EI circuit pack received a request for which the referenced VC was in the wrong call state.	
1093 1109	ATM-EI circuit pack received a request for which the VPI/VCI pair was invalid or out of range.	
1094 1110	ATM-EI circuit pack received a request to add a party to an existing VC. The add party request failed, and a retry was not possible.	
1095 1111	ATM-EI circuit pack in link recovery after the lower ATM layer (Q.SAAL portion of the protocol stack) failed. This can occur when the connection to the ATM switch failed, perhaps because the: <ul style="list-style-type: none"> 1 ATM switch rebooted 1 fiber between the ATM switch and the ATM-EI circuit pack disconnected 	
1096 1112	ATM-EI circuit pack received an error from the local protocol stack for which no more detailed cause was specified.	
1102	ATM-EI circuit pack asked to create more connections that it was capable of creating.	
1103	ATM-EI circuit pack detected an illegal message from software. Check the Error Log for CONN-M errors for more information.	
2 of 3		

Table 35: ATM Error Types 1024 - 1151 3 of 3

Error Type	Description	General problem
1113		Problems detected by the board terminating the connection
3 of 3		

1. Test the ATM-EI circuit pack (*test board location*) and investigate further based on each test's results. If every test passes, the error was a transient problem.

Aux Data values: For Setup and Add Party connection request failure type, the port-network and the Angel number of the destination ATM-EI circuit pack are logged Aux Data values in the form XXYYYY, where

- | port-network number = XX
- | Angel number = YYY

Since you need to know the slot number also, [Table 36: Error Type 1024-1151 Converted Aux Data Values](#) converts the Aux Data to slot numbers.

Table 36: Error Type 1024-1151 Converted Aux Data Values 1 of 2

2 of 2										

- k. **Error type 1153:** The ATM connection audit found some discrepancy in the firmware’s VC token numbers and live VCs. The problem is rectified in firmware and no action is needed. This is an indication of an event only.
- l. **Error Type 1281:** The ATM circuit pack cot talk to the ATM switch. The loss of high-level signal error indicates operational problems of equipment located outside of the circuit pack and the fiber connected to the board. Aux Data values are listed in [Table 37: Error type 1281 Aux Data and repair procedures](#).

Table 37: Error type 1281 Aux Data and repair procedures 1 of 3

Aux Data	Alarm Description	Repair procedure
15	SYSCLOCK failed	<p>The board is not locked to the TDM backplane clock signal. This is probably due to a Tone-Clock problem.</p> <ol style="list-style-type: none"> 1. Check for TDM-BUS or TONE-BD errors in the Error Log. 2. If no other problems are present, reset the circuit pack (reset board location)
16	Loss of Signal: LOS	<p>The fiber is not connected properly to the ATM-EI board or ATM switch (or to the multiplexer section [MUX] if present).It is possible that the board transceivers are not functioning properly.</p> <ol style="list-style-type: none"> 1. Run test board location. 2. If Test #1259 fails, connect a fiber back-to-back in a looped mode (one strand of fiber connecting the transmit transceiver to the receive transceiver of the board) and see if the amber LED flash goes away. If it does, the problem is off-board. 3. If the amber LED continues to flash, replace the circuit pack.
17	Loss of Frame: LOF	<p>The fiber signal cot obtain or maintain STM-1/OC-3 framing.</p> <ol style="list-style-type: none"> 1. Try to move the fiber on the ATM switch side to a different port. This could require administration on the ATM switch. 2. If the problem persists, reset the circuit pack (reset board location).
18	Multiplexer Section Alarm Indication Signal: MS_AIS	<p>There is a major problem on the far end (between multiplexer section [MUX] and the switch) that prohibits the circuit pack from sending a valid signal.</p> <ol style="list-style-type: none"> 1. See if the ports at the MUX and/or the ATM switch are connected snugly. 2. Run test board location. 3. If Test #1259 fails with Error Code 18, connect a fiber back-to-back in a looped mode (one strand of fiber connecting the transmit transceiver to the receive transceiver of the board) and see if the amber LED flash goes away. 4. If it does, the problem is off-board. 5. If the amber LED continues to flash, replace the circuit pack; if the error persists, escalate the problem.
1 of 3		

Table 37: Error type 1281 Aux Data and repair procedures 2 of 3

Aux Data	Alarm Description	Repair procedure
19	Multiplexer Section Remote Defect Indicator: MS_RDI	<p>The far end is detecting a major problem with the signal that this board is transmitting.</p> <ol style="list-style-type: none"> 1. Make sure the ATM switch port (or a MUX port, if present between ATM switch and the ATM-EI board) is the same as the ATM-EI circuit pack's cable interface. 2. Run test board location. 3. If Test #1259 fails with Error Code 19, connect a fiber back-to-back in a looped mode (one strand of fiber connecting the transmit transceiver to the receive transceiver of the board) and see if the amber LED flash goes away. 4. If it does the problem is off-board. 5. If the amber LED continues to flash, replace the circuit pack; if the error persists, escalate the problem.
20	Loss of pointer: LOP	<p>ATM framer chip is unable to access the payload part of the signal.</p> <ol style="list-style-type: none"> 1. Reset the board (reset board location). 2. If the error persists replace the board.
21	Path Signal Error (PSL) (STM1/SONET)	<p>The incoming signal payload is not set up for transmission of ATM data.</p> <ol style="list-style-type: none"> 1. Make sure the ATM switch port (or a MUX port, if present between ATM switch and the ATM-EI board) is the same as the ATM-EI circuit pack's cable interface.
22	High-level Path Alarm Indication Signal: HP_AIS	<p>The payload is invalid.</p> <ol style="list-style-type: none"> 1. Make sure the ATM switch port (or a MUX port, if present between ATM switch and the ATM-EI board) is the same as the ATM-EI circuit pack's cable interface. 2. Run test board location. 3. If Test #1259 fails with Error Code 22, connect a fiber back-to-back in a looped mode (one strand of fiber connecting the transmit transceiver to the receive transceiver of the board) and see if the amber LED flash goes away. 4. If it does the problem is off-board. 5. If the amber LED continues to flash, replace the circuit pack.
2 of 3		

Table 37: Error type 1281 Aux Data and repair procedures 3 of 3

Aux Data	Alarm Description	Repair procedure
23	High-level path Remote defect Indicator: HP_RDI	<p>The far end is detecting a major problem with the signal that this board is transmitting. The transmitted payload is invalid.</p> <ol style="list-style-type: none"> 1. Make sure the ATM switch port (or a MUX port, if present between ATM switch and the ATM-EI board) is the same as the ATM-EI circuit pack's cable interface. 2. Run test board location. If the Test #1259 fails with Error Code 23, connect a fiber back-to-back in a looped mode (one strand of fiber connecting the transmit transceiver to the receive transceiver of the board) and see if the amber LED flash goes away. 3. If it does, the problem is off-board. 4. If the amber LED continues to flash, replace the circuit pack.
24	Loss of cell delineation (LCD)	<p>On board ATM framer chip is not able to frame cells based on the cell header.</p> <ol style="list-style-type: none"> 1. Reset the board (reset board location). 2. If the error persists, replace the board.
27	SIGCON_DOWN ATM switch high level signal	<p>The board cot communicate with the ATM switch.</p> <ol style="list-style-type: none"> 1. Busyout the board with busyout board location. 2. Test the board with test board long location. 3. Release the board with release board long location. 4. If Test #1260 fails, replace the board. 5. If Test #1260 passes, make sure the ATM address on both the server and the ATM switch sides are the same for this board. 6. If the address is the same, change the port on the ATM switch side. This could require administration on the ATM switch. 7. If the error is resolved, the problem is on the ATM switch port.
3 of 3		

- m. **Error Type 1537:** LAN bus time out. The circuit pack is transmitting a packet larger than 1,024 bytes. Replace the circuit pack.
- n. **Error Type 1538:** A hyperactive ATM-EI circuit pack is generating an excessive amount of control messages to the processor. When this error is generated, the system automatically resets the ATM-EI.

Duplicated PNC?	Then:
Yes	service to the PN is disrupted
No	the system switches to the standby PNC

Communication Manager Maintenance Object Repair Procedures

1. Enter `reset board location` for this ATM-EI circuit pack.
 2. If the same error persists, replace the ATM-EI circuit pack.
- o. **Error Type 1793:** LANHO transmit FIFO overflow error (the transmit FIFO RAM buffers on the circuit pack overflowed). This most likely indicates a hardware problem on the circuit pack because the speed of the LAN/packet bus is much higher than the speed of the link connected to the port.
1. Test the ATM-EI circuit pack (`test board location`).
 2. If Test #598 fails again, replace the ATM-EI circuit pack.
- p. **Error Types 2049 and 2050:** The ATM-EI clock generation is out of lock with the backplane system clock.
1. Test the ATM-EI circuit pack (`test board location`).
 2. If Test #304 fails, follow the repair procedures suggested for this test.
- q. **Error Type 2305:** Too many parity errors on data received from the LAN/packet bus (could be due to packet bus problems).
1. Test the ATM-EI circuit pack (`test board location`).
 2. If Test #598 fails, follow the repair procedures for [Packet Interface Test \(#598\)](#).
 3. If the test passes, look for and resolve any PKT-BUS (packet bus) alarms/errors.
 4. If there are no PKT-BUS errors and the problem persists, escalate the problem.
- Error Type 2309:** The packet-interface chip (LANHO) is malfunctioning. Perform the following steps:
5. Test the ATM-EI circuit pack (`test board location`).
 6. If Test #598 fails, follow the repair procedures for [Packet Interface Test \(#598\)](#).
- r. **Error Type 2561:** ATM-EI 2-way transmission failure (circuit pack is having problems creating connections to other PNs in the system).
1. Test the ATM-EI circuit pack (`test board location`).
 2. Follow the repair procedures suggested for [Expansion Interface 2-Way Transmission Test \(#241\)](#).
- s. **Error Types 2817 and 2818:** A bad DSP was detected on the ATM-EI circuit pack.

Error Type	Description	Aux Data indicates
2817	DSP test failure	The Aux Data field contains the following information about the failed DSPs: X is the number of talker DSPs Y is the number of listener DSPs Z is the number of echo-cancelling DSPs
2818	One or more DSPs failed	DSP number that has failed

1. Test the ATM-EI circuit pack (*test board location*).
 2. Follow the repair procedures for any test that fails.
- t. **Error Type 3329:** The on-board LANHO chip is insane, possibly due to a problem in packet bus arbitration, the transmission line frame, or the circuit pack itself. The circuit pack cot talk to the packet bus.

If the packet bus is alarmed:

1. Resolve any PKT-BUS errors. The probability of this error being related to a packet bus problem increases with the number of other circuit packs using the bus that are also showing this error.

If the packet bus is *not* alarmed:

2. Reset the circuit pack (*reset board location*).
3. If the problem persists, replace the ATM-EI circuit pack.

If the system has a duplicated PNC, and the inline error received is from an active ATM-EI, the system switches to the standby PNC.

 **CAUTION:**

If the system does not have duplicated PNC, services to the PN could be disrupted.

- u. **Error Types 3585 and 3586:** Board major component failure. A failure of critical components involved in the operation of the circuit pack. If the system has a duplicated PNC and the inline error received is from an active ATM-EI, the system switches to the standby PNC.

 **CAUTION:**

If the system does not have duplicated PNC, services to the PN could be disrupted.

Error Type 3585

Aux Data (Error Type 3585 only):

Aux Data	Description
1	ATM framer failure
2	NCE failed (only from ATM-EIs in PN)
4	TDM_PLD_FAILED
5	DSP_ALL FAILED
6	Receive Network Processor (RNP) failure

Communication Manager Maintenance Object Repair Procedures

Aux Data	Description
7	Transmit Network Processor (TNP) failure
8	MEMORY read/write failure

1. If the system has duplicated PNC:
 - a. Test the ATM-EI (*test board location 1*).
 - b. If Error 3585 is detected again, or if the board is not recognized anymore, replace the ATM-EI circuit pack.
2. If the system does *not* have duplicated PNC and the circuit pack is in a PN:
 - a. Replace the ATM-EI circuit pack.

Error Type 3586: Framer Looparound test (#1260) failed.

Aux Data (Error Code 3586 only):

Aux Data	Description
2	Packet path failed
3	Circuit path failed
4	TDM loop cot be created
5	Packet loop cot be created

3. If Error Type 3586 is detected again, replace the circuit pack.
 - v. **Error Type 3841:** The board received a message from the switch that it does not recognize, and the board responded with an inconsistent down link error message. This error does not affect service, and no action is required.
 - w. **Error Type 3842:** The circuit pack received data from the packet bus faster than it could distribute the data to its endpoint. This circuit pack should be able to recover by itself, and no action is necessary.
 - x. **Error Type 3843:** The firmware on the circuit pack is reporting a resource that is low. This error does not affect service and no action is required.

- y. **Error Type 3999**: The circuit pack sent a large number of control channel messages to the switch within a short period of time.

If	Then
Error Type 1538 is also present	The circuit pack is taken out of service
Error Type 1538 is absent	The circuit pack is not taken out of service, but has generated 50% of the messages necessary to be considered hyperactive. This can be normal during heavy traffic. If the error is logged during light traffic, it can indicate a problem with the circuit pack or the equipment attached to it.

- z. **Aux Data 32767** for any error log entry indicates that an alarmed ATM-EI was busied out and then released. When this occurs, existing service-affecting alarms must be preserved. Typically, every alarm is resolved when the ATM-EI is released. Therefore, the Alarm and Error Logs must be repopulated with the alarms present at time of busyout. This Aux Data indicates that existing Error Type and Error Log time stamps are no longer valid because they were lost when the circuit pack was released.

Demand test descriptions and error codes

Investigate tests in the order presented. By clearing errors associated with the first test, errors generated from other tests may also be cleared. Click on the link to see the full description of the test, error codes, and recommended actions.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND ¹
ATM Board Time Of Day Update (#1261)		X	ND
Expansion Interface Control Channel Test (#316)	X	X	ND
Packet Interface Test (#598)	X	X	ND
ATM Board DSP Test (#1293)	X	X	ND
Expansion Interface 2-Way Transmission Test (#241)	X	X	ND
ATM Board Framing Looparound Test (#1260)		X	D
ATM Crosstalk Test (#1298)		X	ND
			<i>1 of 2</i>

Communication Manager Maintenance Object Repair Procedures

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND ¹
Expansion Interface Lock Query Test (#304)	X	X	ND
ATM Board Error Query Test (#1259)	X	X	ND
The following test is executed as part of the <code>reset board</code> command			
ATM Board Reset (#1256)			D
			<i>2 of 2</i>

1. D = Destructive, ND = Nondestructive

Note:

To get a better indication of a problem's location, test both ATM-EI circuit packs on the associated fiber link, whether the circuit packs are both ATM-EI circuit packs or not.

ATM-INTF (ATM Interface)

S8700-series Fiber-PNC

MO Name in Log	Alarm Level	Initial Command to Run	Full Name of MO
ATM-INTF	WRN	<code>test board location</code>	ATM interface board

The system recognizes a TN2305/6 as an ATM interface board (ATM-INTF) unless it has an assigned personality (`add atm pnc` or `add atm trunk`). ATM-INTF does not have an associated maintenance strategy, although the:

- 1 `list config` and `change circuit-pack` display information regarding the board
- 1 `test board` runs an on-demand Control Channel test
- 1 `reset board` resets the board

[Table 38: ATM-EI circuit packs for ATM PNC](#) lists circuit packs that are ATM-EI boards if they are administered to provide ATM port-network connectivity (ATM PNC).

Table 38: ATM-EI circuit packs for ATM PNC

Circuit Pack	Fiber	Echo Cancellation
TN2305	Multimode	Yes
TN2306	Single-mode	Yes

Note:

Always replace an ATM-EI circuit pack with the same type.

Error log entries and recommended actions

Table 39: ATM-INTF Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Recommended Action
23 (a)	0	None	WRN	Off	
125 (b)		None	MINOR	On	
217 (c)	0	None	WRN	Off	

Communication Manager Maintenance Object Repair Procedures

Notes:

- a. **Error Type 23:** The ATM expansion interface circuit pack is administered through a **change circuit-pack** command, but has not been inserted into the system. Insert the circuit pack.
- b. **Error Type 125:** A wrong circuit pack is located in the slot where this circuit pack is logically administered. To resolve this problem either remove the wrong circuit pack or insert the logically-administered circuit pack.
- c. **Error Type 217:** The ATM circuit pack is physically present but has not been given a personality. Remove the circuit pack or administer it using **add atm pnc** or **add atm trunk**.

Demand test descriptions and error codes

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND
Control Channel Looparound Test (#52)	X	X	Nondestructive

ATM-NTWK (ATM Network Error)

S8700-series Fiber-PNC

MO Name in Log	Physical Name in Error Log ¹	Alarm Level	Full Name of MO
ATM-NTWK	ATUUP	WRN	ATM Network Error
ATM-NTWK	location	WRN	ATM Network Error

1. *AT* indicates it is an ATM switch-related address, *UU* is the connection number. The connection number can be converted into a board location with `display atm pnc uu`, which shows the translations for the board that reported the ATM network error. *P* indicates if the ATM-EI board (reporting the ATM network error) is on the PNC's A side or the B side. If the system is simplex, only A is valid.

In an ATM PNC configuration, a proprietary Center Stage Switch (CSS) is replaced by an ATM network. Because CSS nodes are replaced by the ATM network in the ATM PNC configuration, SNI boards are no longer needed. In place of the SNI boards, ATM Expansion Interface (EI) or ATM Circuit Emulation Service (CES) boards are connected to an ATM switch port over a fiber-optic cable. The ports on the ATM switch are under control of its maintenance software. Refer to *ATM Installation, Upgrades, and Administration using Avaya Communication Manager*, for more information.

An error against ATM-NTWK indicates a problem in the ATM network (including the ATM switch) that is affecting service quality. These error events are either:

- 1 Reported by the ATM network to an ATM EI or ATM CES board
- 1 Detected by either the ATM EI or ATM CES board itself

Since these errors are **not** related to the ATM EI or ATM CES board, they are not reported against the ATM-EI or ATM-TRK MO. However, some of these errors invoke alarms that require action by the system's maintenance software, while other log-only errors require no action.

Error Codes and Aux Data values

The Cause Code/Error Type information is shown in [Table 40: Error codes and Aux Data values ATM-NTWK](#). These are the possible errors that can be logged against ATM-NTWK.

Communication Manager Maintenance Object Repair Procedures

If ATM-NTWK receives more than 6 errors, the most recent are discarded.

Table 40: Error codes and Aux Data values ATM-NTWK 1 of 6

Cause Code/ Error Type	Aux Data	Cause Codes Description
NORMAL EVENTS		
0	(a)	Network unreachable
1	(a)	Unallocated (unassigned) number. This cause indicates that the called party cot be reached because, although the number is in a valid format, it is not currently assigned (allocated).
2	(a)	No route to specified transit network. This cause indicates that the equipment sending this cause has received a request to route the call through a particular network that it does not recognize, either because the transit network does not exist or because that particular transit network does not serve the equipment that is sending this cause. This cause is supported on a network-dependent basis.
3	(a)	No route to destination. This cause indicates that the called party cot be reached because the network through which the call has been routed does not serve the destination desired. This cause is supported on a network-dependent basis.
10	(a)	VPCI/VCI unacceptable. This cause indicates that the virtual channel most recently identified is not acceptable to the sending entity for use in this call.
16	(a)	Normal call clearing. This cause indicates that the call is being cleared because one of the users involved in the call has requested that the call be cleared. Under normal situations, the source of this cause is not the network.
17	(a)	User busy. This cause indicates that the called party is unable to accept another call because the user busy condition has been encountered. This cause value can be generated by the called user or by the network.
18	(a)	No user responding. This cause is used when a called party does not respond to a call establishment message with a connect indication within the prescribed period of time allocated.
1 of 6		

Table 40: Error codes and Aux Data values ATM-NTWK 2 of 6

Cause Code/ Error Type	Aux Data	Cause Codes Description
21	(a)	Call rejected. This cause indicates that the equipment sending this cause does not wish to accept this call, although it could have accepted the call because the equipment sending this cause is neither busy nor incompatible. Note: If the call was rejected by the far-end ATM-EI or ATM-CES board, there could also be additional information about this rejection in an ATM-EI error log entry. Look for an ATM-EI or error with an Error Type between 1104 and 1119 inclusive, with approximately the same time stamp as this error.
22	(a)	Number changed. This cause is returned to a calling party when the called party's number indicated by the calling user is no longer assigned. The new called party's number can optionally be included in the diagnostic field. If a network does not support this capability, cause number 1 " <i>unassigned (unallocated) number</i> " is used.
23	(a)	User rejects every call with CLIR (calling line identification restriction). This cause is returned by the called party when the call is offered without calling party's number information and the called party requires this information.
27	(a)	Destination out of order. This cause indicates that a user-indicated destination could not be reached because a signaling message could not be delivered to the remote user over the destination's interface (for example, a physical-layer or SAAL failure at the remote user, or remote user's equipment is off line).
28	(a)	Invalid number format (address incomplete). This cause indicates that the called user could not be reached because the called party's number is not in a valid format or has insufficient digits.
30	(a)	Response to STATUS ENQUIRY. This cause is included in the STATUS message when the reason for generating the STATUS message was the prior receipt of a STATUS ENQUIRY message.
31	(a)	Normal, unspecified. When no more specific cause values apply, this cause reports a normal event.
32	(a)	DTL transit not-my-node ID
RESOURCE UNAVAILABLE		
35	(a)	Requested VPCI/VCI not available. This cause indicates that the requested VPCI/VCI is not available. This can be caused by mismatched VCI ranges on different ATM switches.
36	(a)	VPCI/VCI assignment failure
2 of 6		

Table 40: Error codes and Aux Data values ATM-NTWK 3 of 6

Cause Code/ Error Type	Aux Data	Cause Codes Description
37	(a)	User Cell Rate not available
38	(a)	Network out of order. This cause indicates that the network is not functioning correctly and that the condition is likely to last a relatively long time. (Immediately retrying the call is unlikely to succeed.)
41	(a)	Temporary failure. This cause indicates that the network is not functioning correctly, but the condition is unlikely to last long. (Immediately retrying the call is likely to succeed.)
43	(a)	Access information discarded. This cause indicates that the network could not deliver access information to the remote user as requested (that is, ATM adaptation-layer parameters, Broadband low-layer information, Broadband high-layer information, or sub-address as indicated in the diagnostic).
45	(a)	No VPCI/VCI available. This cause indicates that no appropriate VPCI/VCI is currently available to handle the call.
47	(a)	Resource unavailable, unspecified. When no more specific cause values apply, this cause reports a resource-unavailable event.
SERVICE OR OPTION UNAVAILABLE		
49	(a)	Quality of Service unavailable. This cause reports that the requested Quality of Service cot be provided.
51	(a)	User cell rate not available. This cause reports that the requested ATM Traffic Descriptor is unobtainable.
57	(a)	Bearer capability not authorized. This cause indicates that a user-requested bearer capability is implemented by the cause-sending equipment, but the user is not authorized to use the capability.
58	(a)	Bearer capability not currently available. This cause indicates that the user-requested bearer capability is implemented by the cause-sending equipment, but the capability is currently unavailable.
63	(a)	Service or option not available, unspecified. When no more specific cause values apply, this cause reports an unavailable service or option event.
65	(a)	Bearer capability not implemented. This cause indicates that its sending equipment does not support the bearer capability requested.
73	(a)	Unsupported combination of traffic parameters. This cause indicates that the combination of traffic parameters contained in the ATM traffic descriptor information element (IE) is not supported.
3 of 6		

Table 40: Error codes and Aux Data values ATM-NTWK 4 of 6

Cause Code/ Error Type	Aux Data	Cause Codes Description
78	(a)	AAL parameters cot be supported.
INVALID MESSAGES		
81	(a)	Invalid call reference value. This cause indicates that its sending equipment received a message with a call reference that is currently inactive on the user-network interface.
82	(a)	Identified channel does not exist. This cause indicates that its sending equipment received a request to use a channel not activated for the call's interface.
88	(a)	Incompatible destination. This cause indicates that its sending equipment received a request to establish a call with either Broadband low-layer information, Broadband high-layer information, or other compatibility attributes that cot be accommodated.
89	(a)	Invalid endpoint reference value. This cause indicates that its sending equipment has received a message with an endpoint reference that is currently idle on the user-network interface.
91	(a)	Invalid transit network selection. This cause indicates that a transit network identification was received in an incorrect format.
92	(a)	Too many pending add-party requests. This cause indicates a temporary condition when the calling party sends an add-party message, but the network rejects the message due to full queues.
93	(a)	AAL parameters cot be supported. This cause indicates that its sending equipment received a request to establish a call with ATM adaptation-layer parameters that cot be accommodated.
PROTOCOL ERROR		
96	(a)	Mandatory information element (IE) is missing. This cause indicates its sending equipment has received a message with a missing IE.
97	(a)	Message type either non-existent or not implemented. This cause indicates that its sending equipment received a message with an unrecognized type, either because the type is undefined, or defined but not implemented by the cause-sending equipment.
4 of 6		

Table 40: Error codes and Aux Data values ATM-NTWK 5 of 6

Cause Code/ Error Type	Aux Data	Cause Codes Description
99	(a)	<p>Information element (IE) either non-existent or not implemented. This cause indicates that its sending equipment received a message with an unrecognized IE, either because the IE's identifier(s) are undefined, or defined but not implemented by the cause-sending equipment.</p> <p>This cause indicates that its sending equipment discarded the IE. However, the equipment could still process the message since this IE was not required.</p>
100	(a)	<p>Invalid contents in information element (IE). This cause indicates that its sending equipment received and implemented an IE. However, one or more of the IE's fields are coded in a way that the cause-sending equipment has not implemented.</p>
101	(a)	<p>Message not compatible with call state. This cause indicates receipt of a message that is incompatible with the call state.</p>
102	(a)	<p>Recovery on timer expiration. This cause indicates that a timer's expiration initiated an error-handling procedure.</p>
104	(a)	<p>Incorrect message length</p>
111	(a)	<p>Protocol error, unspecified. When no more specific cause values apply, this cause reports a protocol-error event.</p>

Communication Manager Maintenance Object Repair Procedures

Notes:

- a. Aux Data values for Setup and Add Party (XX = port network, YYY = location code).
[Table 41: Location codes from Aux Data values](#) is a list of UNI 3.1 location codes:

Table 41: Location codes from Aux Data values

Setup (Location Code)	Add Party (Location Code)	Location Code Meaning
0	500	User
1	501	Private network serving the local user
2	502	Public network serving the local user
3	503	Transit network
4	504	Public network serving the remote user
5	505	Private network serving the remote user
7	507	International network
10	510	Network beyond interworking point

- b. **Error Types 257 to 300**: displays the destination PNC connection number of an ATM Network connection that is experiencing an impaired path. The connection number is obtained by subtracting 256 from the number that is shown in the Error Type field. For example:

If the Error Type field = 263, subtract 256, which equals 7, the PNC destination connection number.

The Aux Data field contains the originating and destination PN number (XXYY). XX = the originating PN #, and YY = the destination PN # for example:

- Aux Data = 302
3 = orig
2 = dest
- Example Aux Data = 1510
15 = orig
10 = dest

- c. **Error Type 301** indicates that there is a system wide impaired path network problem.

Note:

Under certain circumstances network errors can be against the ATM EI board.

d. Error Type 769: ATM CLP (Cell Loss Priority) Bit Errors

The ATM cell header has a bit called the cell loss priority (CLP) bit. The bit indicates one of two states: the cell is eligible for discarding, or it is not. In an ATM configuration, every cell is transmitted into the ATM network with the CLP bit set to 0 indicating that these cells are NOT eligible for discarding. Should the system ever receive a cell from the ATM network with the CLP bit set to 1 (discard eligible), an entity in the ATM network modified the bit during transit. Generally, an ATM network switch sets the CLP bit to 1 (discard eligible) only if the cell fails to conform to the cell rate specified in the traffic contract for the VC. However, Communication Manager cell emissions conform with the VC traffic contract. Therefore, the presence of a non-conforming cell implies that something else in the ATM network switch is setting the CLP bit in some cells, the ATM switch can also be policing out (discarding) cells which do not conform to the traffic contract. This error can occur together with other errors such as:

“Excessive AAL-5 CRC errors” or
 “Excessive LAP-D retransmissions”

These errors affect SVCs with Variable Bit Rate (VBRnt) traffic contracts. VBR SVCs transport system links such as EAL, PACL, and PRI links. Again, this indicates problems with cell transmissions in the ATM network.

If cell discard is happening generically in the ATM network, other symptoms can affect the Constant Bit Rate (CBR) SVCs including audible artifacts in talk paths, failure of modems over voice lines, and “Cell Underruns” - see note (f).

e. Error Type 1025: ATM Congestion Bit Errors

The ATM cell header has a bit called the congestion bit. In Communication Manager ATM, every cell is transmitted into the ATM network with the congestion bit set to 0 (congestion not experienced). Should the system ever receive a cell from the ATM network with the congestion bit set to 1 (congestion experienced), an entity in the ATM network modified the bit during transit. It simply indicates that the ATM network is experiencing heavy traffic.

During periods of congestion, the ATM network can choose to discard cells even though those cells conform to their traffic contracts. Should the ATM network discard cells, errors such as the following can occur:

“Excessive AAL-5 CRC errors”
 “Excessive LAP-D retransmissions”.

These errors affect SVCs with Variable Bit Rate (VBRnt) traffic contracts. VBR SVCs transport system links such as EAL, PACL, and PRI links. Symptoms that can affect the Constant Bit Rate (CBR) SVCs include audible artifacts in talk paths, failure of modems over voice lines, and “cell Underruns” – see note (f).

f. Error Type 1281: ATM Cell Underruns

Communication Manager ATM monitors for cell underrun conditions on SVCs with Constant Bit Rate (CBR) traffic contracts or on ATM CES trunks. In either case, cells are expected to arrive at a fixed rate. If cells arrive below that rate, an underrun condition exists. The most likely cause of cell underruns is a problem with cell transmission through the ATM network.

Communication Manager Maintenance Object Repair Procedures

Possible symptoms include audible artifacts in talk paths and failure of modems over voice lines. If cell loss is happening generically in the ATM network, other symptoms like “excessive AAL-5 CRC errors” or “excessive LAP-D retransmissions” are possible on SVCs with Variable Bit Rate (VBRnt) traffic contracts. The VBR SVCs transport system links such as EAL, PACL, and PRI links.

Another ATM board within the system originally generated the arriving cells at the specified traffic contract rate. In order to have arrived at a lower rate, these cells were either slowed during transmission or possibly discarded by the ATM network. This indicates problems with cell transmission in the ATM network. Consult the ATM network vendor. Ask about cell delay variation, cell discard, and traffic policing.

Cell underruns often happen in conjunction with cell overruns. If both occur, it further indicates the ATM network.

g. **Error Type 1537:** ATM Cell Overruns

Communication Manager ATM monitors for cell overrun conditions on SVCs with Constant Bit Rate (CBR) traffic contracts or on ATM CES trunks. In either case, cells are expected to arrive at a fixed rate. If cells arrive above that rate, an overrun condition exists. The most likely cause of cell overruns is a problem with cell transmission through the ATM network.

Both cell underruns and overruns are typical symptoms of cell transmission problems like cell jitter or delay. The ATM board attempts to compensate somewhat by buffering cells. However, if the ATM network transmission delays are high, the board could conclude that it has seen a cell overrun because it has exhausted all of its buffer space.

If cell underruns or both cell underruns and overruns occur, indict the ATM network. Consult the ATM vendor. Ask about cell delay variation, cell discard, and traffic policing.

Another much less likely cause of cell overruns is that an ATM board is generating cells above the traffic contract rate. Suppose, a board somehow generates cells too quickly. The ATM network likely reacts by at least setting the CLP bit in the cells that exceed the traffic contract (see note (d) for ATM CLP errors). The ATM network can also discard the excess cells.

If only cell overruns occur, locate the ATM board generating those cells. Execute `test board long`. If the board passes, then the ATM network remains the likely cause of transmission problems. Consult the ATM network vendor. Ask about cell delay variation, cell discard, and traffic policing.

h. **Error Type 1793:** ATM lost cells:

The ATM board receiving the CBR cell stream is detecting out-of-sequence AAL1 sequence numbers, above the defined threshold. This normally indicates that the ATM network has lost the missing cells. In this case, “lost” could mean that the cells were, for example, policed out, lost to congestion, or misdirected to another endpoint.

The likely user-visible symptoms of lost cells are missing talk paths or poor voice quality.

The “lost cells” error can help you diagnose cell underrun problems. When cell underruns are accompanied by lost cells errors, the lost cells could have caused the underruns. But if you have cell under runs without lost cells, it could indicate that the underruns were due to network jitter instead. It is also possible that network jitter can cause both cell underruns and lost cells, if the jitter is so severe it causes the cells to violate their traffic contract.

When accompanied by congestion or CLP errors, the congestion or CLP can be causing the lost cells.

When accompanied by cell overrun errors, the cell overruns can be causing the TN2305 to discard cells, which in turn can show up as lost cells.

Lost cells without other errors can indicate that cells are being corrupted, especially the AAL1 sequence number.

In any case, consult your ATM network vendor about possible causes. Look for jitter (cell delay variation), cell discard, and traffic policing.

ATM PNC-DUP (ATM PNC Duplication)

S8700-series Fiber-PNC

MO Name in Log	Alarm Level	Initial Command to Run	Full Name of MO
PNC-DUP	NA	<code>status pnc</code>	PNC duplication

The PNC-DUP MO tracks the health of the active and standby PNCs, controls pled and spontaneous interchanges, and manages related functions such as double call refresh and unrefresh, antithrashing, and so on. The main responsibility of PNC-DUP is to recover the system to full service in the event of a fault. In the event of multiple faults, PNC-DUP does its best to maximize service continuity.

Note:

ATM PNC-DUP behaves differently when the system is running the ATM PNC feature. While not a separate MO, this discussion explains the unique behavior of PNC-DUP under the ATM PNC feature.

In critical-reliability systems, the following components comprising the port-network connectivity (PNC), are duplicated:

- 1 ATM-Expansion Interface (ATM-EI) circuit packs in port networks (PNs)
- 1 Fiber-optic cables connecting the above circuit packs to the ATM Switch Interface Modules
- 1 ATM Switch

Although not part of the PNC, Tone-Clock circuit packs are also duplicated in each PN. ATM PNC systems can have up to 64 PNs.

PNC duplication architecture utilizes an active/standby duplication scheme in which one complete set of PNC components supports call processing, while the duplicate PNC is held in reserve. All calls on the active PNC are simultaneously set up, or shadowed, on the standby PNC in order for it to be capable of instantly assuming active status when necessary, allowing for interchanges without service disruption (in the case of single faults).

PNC duplication does not introduce any additional types of hardware or hardware faults, and there are no tests associated with the PNC-DUP MO. Instead, its error log entries contain useful information about the occurrence and causes of interchanges in order to facilitate diagnosis of problems, which can then be addressed by using the documentation for the individual MO involved.

PNC-DUP Related Commands

[Table 42: PNC-DUP Commands](#) lists the PNC-DUP related commands. Their output forms are fully described in *Maintenance Commands for Avaya Aura™ Communication Manager, Media Gateways and Servers (03-300431)*.

Table 42: PNC-DUP Commands

Command	Description
<code>status pnc</code>	Shows information about both PNCs' operational status, including state of health, alarms, busyouts and locks.
<code>reset pnc interchange</code>	Initiates a demand PNC interchange. If the standby is healthy (all-zero state-of-health indexes), there is no effect on service. Otherwise, calls may be dropped.
<code>set pnc</code>	Locks or unlocks the active PNC, preventing interchanges. Does not interfere with double call setup.
<code>busyout pnc</code>	Removes the standby PNC from service. See also the section on busyout of PNC components.

Busyouts and PNC-DUP

`Busyout pnc` puts the standby PNC in the busyout state. In this condition:

- 1 Double call set up is turned off.
- 1 The standby PNC is unrefreshed; existing duplicate call connections are removed.
- 1 PNC interchanges are prevented.

Upon release, interchanges are re-enabled and a global refresh of double call setup on the standby is performed.

When PNC duplication is in effect:

- 1 An active PNC component can be busied-out.
- 1 A standby PNC component can only be busied-out when the standby PNC is first busied-out.
- 1 The standby PNC can be released unless all standby PNC components are released.

Enabling and Removing PNC Duplication

To Enable PNC Duplication

To enable PNC duplication, perform the following sequence of steps:

1. Enable administration of PNC-DUP on the **change system-parameters customer-options** screen.
2. Fully administer duplicate ATM PNC connectivity. Verify by **list atm pnc**. Or for IP duplication, go to step three.
3. Fully administer IPSI duplication (**ipserver-interface duplication**). Verify by using **list ipserver-interface**.
4. Activate PNC-DUP through the **change system-parameters duplication** screen. This is not allowed if any component of either PNC (A or B) is busied out.
5. The system must insert all connectivity-related components for both standby and active PNC, a process that takes up to 5 minutes, depending upon circuit pack insertion. The process finishes when the first terminal login prompt appears.
6. The PNC-DUP initialization anti-thrashing timer must expire (this occurs 5 minutes after completion of board insertion, PNC interchange, or system reset of level 2 or higher).

To Disable PNC Duplication

To disable PNC duplication perform the following sequence of steps:

1. Verify that the A-PNC is active. A forced interchange may be required. See **reset pnc**.
2. Busyout the standby PNC (B-PNC).
3. Turn off the system parameter for PNC-DUP through **change system-parameters duplication**.
4. Remove the B-PNC connectivity by removing the Board Locations on the **change fiber** screen for ATM PNC.
5. Remove the B-PNC circuit packs (ATM-EI boards). Enter **change circuit-pack location**.
6. Disable administration of PNC duplication on the **change system-parameters customer-options** screen by changing the **PNC Duplication** field to **n**.

Notes:

1. Alterations to PNC that involve only the addition of connectivity can be done with PNC-DUP operational.
1. Alterations requiring the removal of connectivity must be done with PNC-DUP removed.

- 1 PNC-DUP must be removed and translations should be saved before making any hardware changes.

Steady State LEDs

The LEDs of PNC components in a stable duplicated system should appear as follows:

- 1 For an **active** ATM EI (functioning as Archangel) in a PN **without** IPSIs, the amber LED's flash pattern is 2 seconds on/200 ms off.
- 1 For a **standby** ATM EI in a PN without IPSIs, the amber LED is off.
- 1 For an **active** ATM EI in a PN **with** IPSIs, the amber LED is on steady.
- 1 For an **standby** ATM EI in a PN with IPSIs, the amber LED is off.

PNC State of Health

PNC-DUP software monitors the health of the two PNCs as determined by their state-of-health (SOH) vectors, and initiates an interchange when the health of the active falls below that of the standby (unless prevented from doing so by a PNC lock, busyout, or antithrashing mechanism). Potentially service-disrupting faults that occur in a PNC's components are reported to PNC-DUP and incorporated in the affected PNC's state of health. The SOHs of both PNCs are displayed on the `status pnc` screen, as shown in [Figure 2: Status PNC screen with standby PNC fully In-Service](#).

Figure 2: Status PNC screen with standby PNC fully In-Service

```

status pnc                                     page 1 of 1
                                PORT-NETWORK CONNECTIVITY

                                Major Alarms: 0                       Major Alarms: 0
                                Minor Alarms: 0                       Minor Alarms: 0
                                Warning Alarms: 0                     Warning Alarms: 0
    
```

PNC State-of-Health Indexes

The Inter-PN Index screen the state-of-health vector is used to track and compare the states of health of both PNCs. The fields making up the indexes are 2-digit numbers separated by periods (.), with each field representing a different class of faults. The fault class fields are arranged in order of decreasing importance from left to right. In other words, each field in the index supersedes the following fields in determining which PNC is healthiest. A fault class drives an interchange only when all of the higher priority fault classes are equal. A zero entry indicates no faults present for that class. Increasing numbers indicate increasingly higher numbers of faults present in that class.

The Inter-PN Index contains four fields (XX.XX.XX.XX). The Inter-PN Index reports faults in connectivity between PNs.

- 1 The meaning of each fault class field is given in [Table 43: PNC State-of-Health Fault Classes](#).
- 1 A zero entry indicates that there are no faults reported.
- 1 Higher numbers indicate increasing number of faults.
- 1 All zeros indicate a perfect state of health.
- 1 Unless the PNCs are locked, the active PNC's state of health should always be equal to or better than the standby's. Otherwise, the system performs a spontaneous interchange.

After a PNC-related alarm is cleared, the system performs a partial refresh of the standby PNC. The corresponding fault class field is not updated to reflect the improved state of health until the refresh is done. The state-of-health indexes do not agree with the current alarm status during this period.

Table 43: PNC State-of-Health Fault Classes

Fault Class	Priority	Description	MOs
FC_EAL	1	Number of PNs with EALs down	EXP-PN
FC_PACL	2	Number of PNs with LINL, RINL, or EI-SNI neighbor link faults	EXP-PN
FC_BFD	3	Number of PNs with BFDL (Bearer Fault Detection Link) faults	SYS-LINK
FC_HW	4	Number of PNs affected by hardware faults in a link having an EI as an endpoint. Enter <code>list atm pnc</code> to see endpoint designations.	ATM-EI

Resolving Poor State of Health

When both PNCs do not have an all-zero SOH (perfect health), use the following steps to identify and repair the problem.

1. Look for PNC component alarms (major or minor) for the PNC side without an all-zero SOH. The standby PNC should be repaired first.
2. Busy-out the standby PNC.
3. Follow the appropriate diagnostic and repair procedures for the alarmed PNC components just as with a simplex PNC. Both the alarm and error logs should be examined to isolate the fault.
4. Verify that the related PNC's SOH is restored to all zeros.
5. Release the standby PNC.

Refresh and Unrefresh of the Standby PNC

In a fully-functional PNC with healthy standby and active sides, the standby PNC has a complete set of call connections corresponding to those in the active PNC. If, however, the standby PNC's state of health degrades, a selective unrefresh of those connections that utilize the faulted component(s) is performed. If the standby PNC's health improves, a selective refresh of connections on the affected route is performed so that call setup is consistent between the active PNC and the healthy parts of the standby PNC.

Communication Manager Maintenance Object Repair Procedures

The **Standby Refreshed?** field on the `status pnc` screen does *not* refer to the selective type of refresh. It refers only to a global refresh that is performed when:

- 1 The system is initialized and PNC duplication is enabled.
- 1 There has been a spontaneous PNC interchange.
- 1 The standby PNC has been released from busy-out.
- 1 A system reset of level 2 or higher has taken place.

The `Refreshed` field may display `yes` when in fact the standby is partially unrefreshed. An interchange into an incompletely refreshed standby results in dropped calls. This can happen when a more severe fault occurs on the active PNC or when `reset pnc interchange` is used with the override option.

PNC Interchanges

PNC spontaneous interchanges occur when PNC duplication software determines that the standby PNC's state of health (SOH) surpasses the active PNC's.

- 1 PNC-DUP executes a spontaneous interchange in response to a message from a PNC component MO indicating that either a fault has occurred on the active PNC or a fault has been resolved on the standby PNC.
- 1 The PNC SOH is compared to the standby PNC, and an interchange occurs if the standby PNC's state of health surpasses the active PNC's.
- 1 A corresponding Major or Minor alarm is logged by the reporting MO, stimulating an alarm report.

When the resolution of a fault on the standby renders it more healthy than a simultaneously-faulted active PNC, the error message indicates the type and location of the *improved* component.

Once the interchange completes, the failed component is on the standby PNC. A demand interchange can be requested in the presence or absence of standby PNC faults. The following sequence of actions can be observed during a fault-free interchange:

1. The ATM-Expansion Interfaces currently acting as archangels in the PNs are deactivated as indicated by the amber LEDs going from flashing to on solid.
2. The ATM-EIs in IPSI connected PNs are interchanged, indicated by the new standby ATM-EI amber LED off and the new active ATM-EI amber LED on steady.
3. One by one, the ATM-EIs in non IPSI connected PNs are interchanged as indicated by new standby ATM-EI amber LED turning off and the new active ATM-EI amber LED flashing (2 seconds on / 200 milliseconds off). At this point, the interchange is functionally complete.

Certain conditions may interfere with the normal execution of the interchange:

1. In a faulted spontaneous interchange, it is possible the PN(s) directly affected by the fault will be the last to interchange.
2. A user directly affected by the single fault instigating a PNC interchange can experience a momentary voice path outage during the switch.
3. If faults exist on both the standby and active PNC, it is possible to have some PNs go out of service while others are returned to service.

In any multifault situation, rely on `status pnc` to determine which is the active PNC.

PNC duplication informs Timing Synchronization maintenance when a PNC interchange has been completed and indicates which PNC is active. This causes Synchronization to audit and ensure that the primary source for synchronization of Tone-Clocks in each PN is supplied by a path associated with the active PNC.

Antithrashing and PNC Interchanges

Following a spontaneous PNC interchange, subsequent PNC interchanges are prevented for 5 minutes. This condition is indicated by **y** in the **Interchange Disabled?** field of the **status pnc** screen. After 5 minutes, the antithrashing timer expires, interchange decisions are re-enabled, and the field displays **n**.

Note:

Should a catastrophic failure occur on the active PNC during the period when the Interchange Disabled? field is set to "yes," there will be no spontaneous PNC interchange.

Demand PNC interchanges also invoke anti-thrashing, but only for a period of 30 seconds. During antithrashing mode, demand interchanges are also prevented unless the override option is specified.

CAUTION:

Use of this option may cause a service disruption.

Repairs on the Standby PNC Components

CAUTION:

If there is a TDM-CLK alarm, system timing may be routed through part of the standby PNC, and circuit switched data may be affected by the following repair procedures. This can happen, for example, when a slave tone/clock circuit pack experiences a loss of signal and switches to receive timing from the standby ATM-EI. In this case TDM-CLK 2305 error is logged, and the clock problem should be addressed first, if possible.

To repair PNC components in a duplicated PNC proceed as follows:

1. Most repairs involve fixing a single fault on the standby PNC. Enter **set pnc lock** or **busy-out pnc** to prevent an interchange into the PNC being repaired.
2. If a faulty component exists on the active PNC, this also means that the standby PNC is more severely faulted. Normally, the *standby* PNC is repaired first, since it is the most severely impaired.

To repair the active PNC (the standby is already repaired), enter **set pnc unlock**, which generates a spontaneous interchange. In a PNC demand interchange with **reset pnc interchange** use the *override-and-lock* qualifier for the active PNC. The *override-and-lock* option ensures that no subsequent interchange can occur during the repair of the standby PNC. A demand interchange may not be necessary if the following conditions drive a spontaneous interchange:

1. The anti-thrashing period from the last interchange has expired.

- 1 The global refresh from releasing the standby PNC has completed.
- 1 The standby PNC's state of health surpasses the active PNC's.

At this point, the faulty component is on the standby PNC, and the PNCs are locked in their current active/standby state.

3. Busyout the PNC with `busyout pnc`.
4. Use fault isolation and component testing procedures for the individual PNC components, just as for a simplex PNC. Replacement of components does disrupt operation of the active PNC.
5. Once the failed component is replaced, use `status pnc` to check the health standby PNC component.
6. When confident that the problem has been resolved, as indicated by an all-zero state of health, unlock (`set pnc unlock`) and release (`release pnc`) the PNC. Note that no further PNC interchange is required since you can test the standby PNC as thoroughly as the active.

Interactions: Server Resets and PNC Interchanges

- 1 A system reset of level 1 (warm), 2 (cold2) or 4 (reboot) does not change which PNC is active. If a PNC interchange was in progress when the reset took place, the PNC interchange continued until completion.
- 1 If a `reset system 1` (warm) takes place during a PNC interchange, the reset is escalated to level 2 (cold2).

Fault Isolation Using Duplicated PNC

In some cases, PNC duplication can aid in the fault isolation procedure. PNC interchanges can be used to help isolate the faulty hardware. Two examples demonstrating this technique follow:

1. There is a fault that can occur in either an IPSI connected PN's ATM-EI or the PKT-INT which cot be readily attributed to one board or the other. If the packet bus transceivers on either the PKT-INT or ATM-EI fail, the two boards cot communicate, but it will not be clear which board is at fault. In this case, a pled interchange of the PNC can be used to indicate which of the two boards. If the interchange:
 - Cures the problem, the ATM-EI was at fault
 - Does not cure the problem, the PKT-INT is suspect (provided there are no PKT-BUS faults)

2. A similar relationship exists for the PN Archangel (EAA - the active ATM-EI) and certain TDM-bus problems. If the EAA is unable to communicate with a port board over the TDM bus, either the EAA has a fault, the port board has a fault, or there is a problem with the TDM bus itself. If TDM bus maintenance tests find no problems with the bus, then it is either the port board or the EAA. It may be simpler to replace the port board than to request a PNC interchange. However, if it is not clear which port board may be at fault or maintenance is being performed remotely, verify that the EAA is not at fault by executing a PNC interchange. If the interchange solves the problem, then the EAA is faulty. If the problem persists after the interchange, but TDM bus maintenance finds no problem, then the port board is faulty.

Error Log Entries

Whenever a PNC interchange takes place, an error is logged against PNC-DUP with a code that conveys information about the cause of the interchange and which PNC became active. There are no alarms associated with PNC-DUP errors, but there should be an alarm against the PNC component that caused the interchange. There are no PNC-DUP test sequences, but `status pnc` provides information regarding the status of the PNCs. The information in [Table 44: Error Code descriptions and Aux Data correlations](#) and [Table 45: Error Log Encode Field Decoding](#) can help to identify which areas of the Alarm Log to investigate to find the source of the problem.

Table 44: Error Code descriptions and Aux Data correlations

Error Code	Description	Aux Data ¹
00000	Error in generating error code	None
1cxpp	Spontaneous Interchange in response to a constraint for A-PNC	Active PNC
2cxpp	Spontaneous Interchange in response to a constraint for B-PNC	Active PNC
51000	Spontaneous Interchange at expiration of SOH validation timer	Active PNC
52000	Spontaneous Interchange upon PNC UNLOCK	Active PNC
53000	Spontaneous Interchange at completion of Global Refresh	Active PNC
60801	PNC Demand Interchange	Active PNC
60800	PNC Demand Interchange with override	Active PNC

1. The Aux Data indicates which PNC became active after the PNC interchange: "0" denotes PNC-A; "1" denotes PNC-B.

Table 45: Error Log Encode Field Decoding

Field	Variable Name	Values	Description
c	Alarm Type	0 1	Alarm retired MAJOR or MINOR alarm on any PNC component
x	Fault class; see description for contributing MOs	0	EAL (Expansion Archangel Link - EXP-PN) carries CCMS messages
		1	PACL (ATM-EI) carries ATM signaling commands from Call Processing to the remote ATM-EI circuit packs
		2	PNC hardware (providing connectivity of PN-to-PN or -ATM-EI)
		5	BFDL (bearer fault detection link) solely for the purpose of detecting bearer faults
pp	Port-network number	0–63	0–2 for constraint class (this is an internal number; add 1 for external port number)

Error log entries and recommended actions

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Recommended Action
18	None	<code>busy PNC-DUP</code>	WRN	ON	<code>release pnc-dup</code>

Note:

The `list config port-network` command displays the cabinet number associated with a PN.

ATM-SGRP (ATM Signaling Group)

MO Name in Log	Alarm Level	Initial Command to Run ¹	Full Name of MO
ATM-SGRP	MIN WRN	<code>test sig-group grp#</code>	ATM-CES Signaling Group

1. *grp#* is the signaling group number (1–166); the test sequence can be either short or long.

ATM-SGRP applies when ATM signaling groups have been administered on an ATM circuit pack as ATM trunks.

[Table 46: ATM-SGR circuit packs](#) outlines the differences between ATM interface circuit packs:

Table 46: ATM-SGR circuit packs

Circuit pack	Channel types	Interface	Fiber	Echo cancellation
TN2305	B and D-Channels	24- or 32-channel	Multimode	Y
TN2306	B and D-Channels	24- or 32-channel	Single-mode	Y

The TN2305 and TN2306 ATM Interface circuit boards are referred to as TN230X for the remainder of ATM-SGRP.

An ATM Signaling Group is a collection of B-Channels for which a given ISDN-PRI signaling-channel port (ATM D-Channel) carries signaling information. ATM B channels (ATM-BCH) carry voice or data and are assigned to ISDN trunks. For more information see [ATM-TRK \(Circuit Emulation Service Circuit Pack\)](#).

The operation of the entire ATM signaling group depends on several other entities:

- 1 ATM-DCH signaling-channel port
- 1 TN230X Interface circuit pack where a D-Channel resides
- 1 System link to the processor via the packet bus

When there are problems with ATM-SGRP (ATM signaling group), also investigate:

- 1 [ATM-DCH \(ATM D-Channel Port\)](#)
- 1 [ATM-BCH \(ATM B-Channel Trunk\)](#)
- 1 [SYS-LINK \(System Links\)](#)
- 1 [PKT-BUS \(Packet Bus\)](#)

Error log entries and recommended actions

Table 47: ATM-SGRP Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Recommended Action
0	0	Any	Any		<code>test sig-group grp#</code>

2305 (g)	Any	Remote Layer 3 Query test (#637)	MIN	OFF	<code>test sig-group grp#</code>
3585 (h)	Port number	None			
3840 - 3928 (i)	Port number	None			

Notes:

- a. **Error Type 1:** switch sent a message to the far-end switch or terminal adapter, and the far end did not respond in the time allowed. Possible causes include link failure and congestion or outage at the far end. The Aux Data field contains layer-3 protocol information used by internal counters.

If no other symptoms are present, no action is required.

If layer-3 communication is down, check for alarms and errors against link components.

Check out other errors against ATM-SGRP, ATM-TRK, and other hardware components on the link. There is no test to clear these errors. The error counter is decremented by 1 every 15 minutes.

Communication Manager Maintenance Object Repair Procedures

- b. **Error Type 18:** the ATM circuit pack has been busied out either with the command `busyout atm sig-grp` or `busyout board location`.
1. Release the ATM signaling group (`release atm sig-grp`) or the circuit pack (`release board location`).
- c. **Error Type 257:** the primary signaling channel connection has been lost for more than 90 seconds.
1. The associated B-Channels are placed in the ISDN Maintenance/Far-End state.
 1. The B-Channels are not usable for outgoing calls, although incoming calls can be accepted.
 1. The switch automatically attempts to recover the signaling link.
 1. Check the results of the [Primary Signaling Link Hardware Check \(#636\)](#) in the test sequence.
 1. When the link does recover, the B-Channels are negotiated back to the In-Service state and their alarms are retired.
 2. When this error occurs, the state of the Signaling Group is changed to out-of-service (verify using the `status sig-group` command).
- d. **Error Type 769:** signaling link hardware error.
Service-affecting failures of the hardware which is used to transport the D-Channel are reported to the ATM CES Signaling Group MO. Maintenance logs this error, places the D-Channel into the OOS state, and raises a board-level alarm. The D-Channel is returned to service, and the alarm is retired once the hardware failure condition clears.
- e. **Error Type 1281:** Degraded PVC alarms indicate that a particular Permanent Virtual Circuit, or signaling group, has encountered sufficient errors to exceed firmware thresholds. Operations can continue but at a lower level of reliability or performance. Firmware filters these alarms so that only one is reported active at a given time. The following inline error is considered a Degraded PVC alarm:
1. Excessive AAL – The AAL layer is experiencing an excessive number of errors in trying to reconstruct Service Data Units (SDUs). Possible causes:
 - Problem with the ATM switch
 - Noisy communication paths on opposite side of ATM switch
 - Unhealthy sending node
 - Congestion at the ATM switch
- f. **Error Type 1793:** Layer 2 Query test for the primary signaling channel failed.
1. Excessive AAL – The AAL layer is experiencing an excessive number of errors in trying to reconstruct Service Data Unit (SDUs). Possible causes:
 - Problem with the ATM switch
 - Noisy communication paths on opposite side of ATM switch
 - Unhealthy sending node
 - Congestion at the ATM switch

g. **Error Type 2305:** The [Remote Layer 3 Query \(#637\)](#) failed. A specific message was sent to the far-end switch, and it did not respond within the time allowed.

1. Investigate elements of the ATM D-Channel(s) (ATM-DCH) for both this switch and the far-end switch.

If Test #637 fails twice in a row, the B-Channels are alarmed and made unavailable for outgoing calls (although incoming calls are still accepted). When Test #637 succeeds and the far-end switch starts responding properly, the ATM trunk (B-Channels) are placed back into normal operation and their alarms retired.

h. **Error Type 3585:** A SERV or SERV ACK ISDN D-channel message has been received by a non-US-type interface (country option other than 1 on the DS1 administration screen). However, these messages are used only for duplex NFAS signaling, which is supported by country protocol 1.

Thus, there may be a mismatch in administration between the local and far-end switches.

1. Consult with the customer's network provider to determine whether the D-Channel is set up correctly on the far-end switch.

i. **Error Type 3840-3928:** These Error Types report certain error messages received by the ATM-SGRP Signaling Group for one of its associated B-Channels. The Aux Data field is the port number of the B channel from which the message was received.

The error code generated equals 3840+x, where x is a Cause Value defined by the ISDN PRI Specification. Note that there is no recommended action for these Error Types; selected ISDN cause values are placed in the log when they are received, but no direct action or alarming is performed solely in response to receiving them. They provide added data that may prove useful when tracking down obscure networking and routing problems. See [Table 48: Descriptions and repair recommendations \(Error Types 3840-3928\)](#) for more information.

Table 48: Descriptions and repair recommendations (Error Types 3840-3928) 1 of 5

Error Code	Description	Recommendation
3842	A request has been made to use a transit network or common carrier that cot be accessed.	From the circuit pack and port number (in the Aux Data field), determine the trunk group against which the error was reported. <ol style="list-style-type: none"> 1. Check every routing pattern containing this trunk group for validity of interexchange carriers requested (IXC field).
1 of 5		

Table 48: Descriptions and repair recommendations (Error Types 3840-3928) 2 of 5

Error Code	Description	Recommendation
3846	The far-end switch has indicated that the B channel (trunk) is not acceptable for use in the call for which it was requested.	This could indicate <ul style="list-style-type: none"> 1. an administration problem (for example, the local switch and the far-end switch have different B-Channels administered) 1. a normal race condition (for example, the local switch has requested use of a B-Channel that the far-end switch had just reserved for use on another call). <ol style="list-style-type: none"> 1. From the circuit pack and port number (in the Aux Data field), determine the trunk group against which the error was reported. 2. Enter <code>status trunk</code> for the indicated trunk. 3. Refer to Table 28: ATM ISDN service states on page 116 for recovery suggestions.
3858	Similar to Error Type 1. The switch sent an ISDN message to the far-end switch or terminal adapter that did not respond in the time allowed.	<ol style="list-style-type: none"> 1. Check for alarms and errors against link components 2. Check out other errors against ATM-SGRP (ATM Signaling Group), ATM-TRK (Circuit Emulation Service Circuit Pack), and other hardware components on the link.
3878	The far-end switch has indicated that the network is not functioning correctly and that the condition may last a relatively long period of time (for example, immediately re-attempting the call may not be successful).	<ol style="list-style-type: none"> 1. From the circuit pack and port number (in the Aux Data field), determine the trunk group against which the error was reported. 2. Consult with the network provider to determine the nature and expected duration of the out of service condition. 3. Consider modifying every routing pattern containing this trunk group, to route calls around the network that is out of service.

Table 48: Descriptions and repair recommendations (Error Types 3840-3928) 3 of 5

Error Code	Description	Recommendation
3890	A request to use a network service (for example, SDN) has been denied. Administration somewhere in the network has indicated that the requested service has not been subscribed to or purchased for this trunk.	<p>This could indicate</p> <ul style="list-style-type: none"> 1 a local administration problem 1 a mismatch between the local administration and that of the network provider. <ol style="list-style-type: none"> 1. From the circuit pack and port number (in the Aux Data field), determine the trunk group against which the error was reported. 2. Display the trunk group screen. <p>If the trunk group is Call-by-Call (the Service Type field is cbc), check every routing pattern screen containing this trunk group to see if the Service/ Feature fields contain the correct network services purchased for this trunk.</p> <p>If the trunk group is not Call-by-Call, check that the Service Type field contains the single network service purchased for this trunk.</p> 3. If local administration appears correct, consult with the customer and/or the network provider to determine the services that the customer has subscribed to for this trunk group.
3892	Protocol detail; may offer a clue if customer is having ISDN calls denied with an unexpected intercept tone.	<ol style="list-style-type: none"> 1. If customer is complaining of unexpected intercept tones when accessing ISDN trunks or PRI endpoints and no other cause can be found, escalate the problem and provide the next tier with this Error Log information.
3 of 5		

Table 48: Descriptions and repair recommendations (Error Types 3840-3928) 4 of 5

Error Code	Description	Recommendation
3894	Protocol detail; may offer a clue if customer is having ISDN calls denied with an unexpected intercept tone.	Do the following: <ol style="list-style-type: none"> 1. Eliminate any transitory state mismatch problems (test port location for the trunk port shown in the Aux Data field). Service State Audit Test (#256) is the important test in the sequence. 2. If Test #256 passes yet the customer continues to complain of unexpected intercept tones when accessing ISDN trunks or PRI endpoints and no other cause can be found, escalate the problem and provide the next tier with this Error Log information.
3905	Protocol detail; may offer a clue if customer is having ISDN calls denied with an unexpected intercept tone.	Do the following: <ol style="list-style-type: none"> 1. If customer is complaining of unexpected intercept tones when accessing ISDN trunks or PRI endpoints and no other cause can be found, escalate the problem and provide the next tier with this Error Log information.
3906	Protocol detail; may offer a clue if customer is having ISDN calls denied with an unexpected intercept tone.	Do the following: <ol style="list-style-type: none"> 1. If customer is complaining of unexpected intercept tones when accessing ISDN trunks or PRI endpoints and no other cause can be found, escalate to the problem and provide the next tier with this Error Log information.
3909	A request to use a network service has been made, but the network has rejected the request because the requested service is not implemented.	Follow the recommendations for Error Type 3890.
4 of 5		

Table 48: Descriptions and repair recommendations (Error Types 3840-3928) 5 of 5

Error Code	Description	Recommendation
3928	A call was denied because of a basic incompatibility between the type of call and either the facilities selected by the routing pattern or the called user itself.	<p>This error might be helpful as a clue if the customer complains of receiving unexpected intercept tone after accessing ISDN trunks or PRI endpoints.</p> <ol style="list-style-type: none"> 1. Determine the trunk group from the circuit pack and port number (in the aux data field) 2. check the BCC fields of the pertinent routing patterns. 3. Also, investigate whether or not the calling and called endpoints are compatible (for example, some ISDN switches may not allow a voice station to call a data extension).

ATM-SYNC (ATM Synchronization)

S8700-series Fiber-PNC

MO Name in Log	Alarm Level	Initial Command to Run	Full Name of MO
ATM-SYNC	MIN	<code>display errors</code>	ATM Synchronization
	WRN	<code>test synchronization</code>	

This section discusses intra-switch synchronization maintenance and the hardware and software components that provide a common reference frequency for reliable digital communications among the system, the ATM switch, and other PBXs, Central Offices (COs) or customer-premises equipment (CPE). Circuit packs involved in synchronization include:

Note:

TN768 or TN780 Tone-Clock circuit packs are not compatible with ATM EIs.

- 1 TN2312 IPSI circuit pack's Tone-Clock circuit
- 1 TN2182 Tone-Clock
- 1 TN722, TN464, and TN767 DS1 Interfaces (all suffixes)
- 1 TN2305/6 ATM Expansion Interface (multimode fiber)

Synchronization is achieved between the S8700-series Server IPSI and the port networks (PNs) through the ATM port-network connectivity (ATM PNC) between the networks. Depending on the network's synchronization plan and the status of synchronization sources, the system timing reference may be:

- 1 The clock circuit pack on the ATM switch
- 1 A DS1 or UDS1 interface circuit pack-tapped T1 input signal connected to the ATM switch clock circuit
- 1 An OC-3 interface circuit pack on the ATM switch

Stratum 4 synchronization extracts timing information directly from

- 1 A DS1 or UDS1 reference
- 1 An OC3 reference
- 1 The ATM switch clock

For further information about synchronization including network synchronization, refer to *DEFINITY® Communications System Network and Data Connectivity*.

Stratum 4 Synchronization

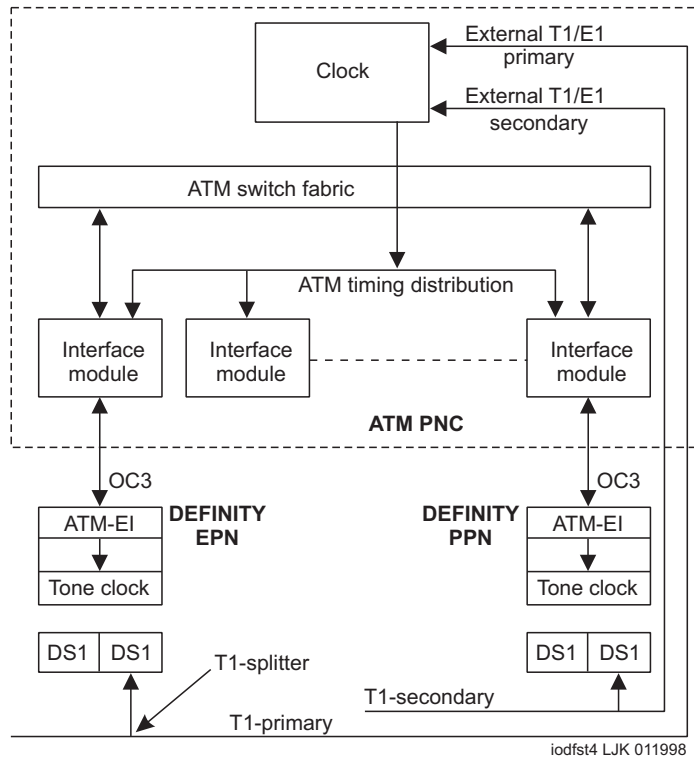

Systems may have primary and secondary synchronization references (DS1/UDS1 interface circuit packs or ATM-Switch) when using Stratum 4 synchronization.

If the primary synchronization reference in [Figure 3: Stratum-4 Synchronization with Unduplicated ATM PNC](#) is providing a valid timing signal, then the flow of system synchronization would travel from the DS1 interface circuit pack in the PN to the ATM switch. The primary DS1 interface circuit pack provides a timing signal for the ATM switch clock circuitry. This synchronization source is then distributed to all of its OC3 Interface Modules. Each ATM Expansion Interface circuit pack uses the received data stream from the ATM switch to generate a timing signal. The Tone-Clock circuits in the PNs use this signal to generate timing for every circuit pack in their respective PNs. All PNs, in the above mentioned scenario are designated the *slave* PNs. The ATM switch is the *master* that contains the system synchronization source. If the primary synchronization reference does not provide a valid timing signal, ATM synchronization maintenance infers a switch to the secondary reference.

If the primary synchronization reference is not providing a valid timing signal, the system automatically switches to the secondary synchronization reference. If the primary synchronization reference is invalid, and if the secondary reference does not provide a valid timing signal or is not administered as a synchronization reference, the switch infers that the local oscillator of the ATM switch provides the system timing source. If the system is using the local oscillator of the ATM switch as the system timing source because the primary and secondary references are providing invalid timing signals, when either the primary or secondary reference becomes valid again, the system switches back to the primary or secondary source. When both the primary and secondary source become valid, the system switches to the primary source, since the primary source is always preferred over the secondary source when both sources are equally healthy.

[Figure 3: Stratum-4 Synchronization with Unduplicated ATM PNC](#) depicts a simplex ATM PNC with T1/OC3 synchronization reference into the ATM switch.

Figure 3: Stratum-4 Synchronization with Unduplicated ATM PNC

Note:

The TN722 DS1 Interface circuit pack does not provide a synchronization reference as reliably as the TN767 or TN464 circuit packs. Therefore, administer the TN767 or TN464 circuit packs as the primary or secondary sources.

Stratum-3 Synchronization

Stratum-3 synchronization is not supported on S8700-series servers with ATM PNC.

Troubleshooting ATM synchronization

A significant part of the Synchronization Recovery Strategy for a S8700-series system with ATM PNC resides in the ATM switch’s clock hardware, firmware, and software. The system monitors synchronization performance and alarms any faulty components. See [SYNC \(Port Network Synchronization\)](#).

ATM-SYNC Commands

Use the commands in [Table 49: ATM-SYNC commands](#) to help troubleshoot ATM-SYNC problems:

Table 49: ATM-SYNC commands

Command	Description
<code>change synchronization</code>	Allows primary and secondary references to be administered for the Stratum 4 option, or <code>ATM-Switch</code> , indicating that the synchronization references are input directly to the ATM switch
<code>status synchronization</code>	Shows the current inferred synchronization reference
<code>status synchronization</code>	Shows the administered primary and secondary synchronization references
<code>disable/enable synchronization-switch</code>	Prevents or allows switching to another synchronization source
<code>test synchronization</code>	Tests the administered synchronization source

Error log entries and recommended actions

Table 50: ATM-SYNC Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Recommended Action
0 (a)	0	Any	Any	Any	<code>test synchronization</code>
1 (b) (h)			WRN MINOR	OFF	
257 (c) (h)			WRN MINOR	OFF	
513 (d) (h)			WRN MAJOR	OFF	
1537 (e)			WRN	OFF	
1793 (f)	0-50		NONE	OFF	
2049 (g)	0		WRN	OFF	

Communication Manager Maintenance Object Repair Procedures

Notes:

- a. **Error Type 0:** Run the short test sequence first. If every test passes, run the long test sequence. Refer to each appropriate test's description, and follow its recommended procedures.
- b. **Error Type 1:** problem with the primary DS1 reference. It is cleared when the primary reference is restored. The following steps should give an indication of the source of the problem:
 1. Check if the primary DS1 interface circuit pack is inserted in the carrier with `list configuration board location`.
 2. Verify that the administered primary reference matches the DS1 reference from the network synchronization plan.
 3. Test the primary DS1 interface circuit pack with `test board location long`. Check the Error Log for DS1-BD or UDS1-BD errors and see [DS1-BD \(DS1 Interface Circuit Pack\)](#) or [UDS1-BD \(UDS1 Interface Circuit Pack\)](#) to resolve any errors associated with the primary DS1 (DS1 or UDS1) interface circuit pack. If the only errors against DS1-BD or UDS1-BD are slip errors, then follow the procedures described in the troubleshooting section above. If no errors are listed in the Error Log for the primary DS1 interface circuit pack, continue with the following steps.
 4. Test the active Tone-Clock circuit in the master PN with `test tone-clock location long`. Check the Error Log for TDM-CLK errors and verify that TDM Bus Clock Test #148 (TDM Bus Clock Circuit Status Inquiry test) passes successfully. If Test #148 fails with an Error Code 2 through 32, see [TDM-CLK \(TDM Bus Clock\)](#) to resolve the problem.
- c. **Error Type 257:** problem with the secondary DS1 reference. It is cleared when the secondary reference is restored. Refer to note (a) to resolve this error substituting `secondary` for `primary` in the preceding resolution steps.
- d. **Error Type 513:** the ATM switch clock is inferred to be providing the timing source for the system. The primary and secondary (if administered) are not providing a valid timing signal. Investigate errors 1 and 257 to resolve this error.
- e. **Error Type 1537:** over half of the DS1s that are administered with slip detection enabled through the **Slip Detection** field set to `y` are experiencing slips. It may take up to 1 hour for these alarms to clear.
- f. **Error Type 1793:** inferred excessive switching of system synchronization references has occurred. When this error occurs, it is inferred that the ATM switch clock has become the synchronization reference for the system. It may take up to 1 hour for these alarms to clear.
 1. Check for timing loops and resolve any loops that exist.

2. Test the active Tone-Clock circuit in the master PN with `test tone-clock location long`.

Check the Error Log for TDM-CLK errors, and verify that TDM Bus Clock Circuit Status Inquiry test (#148) passes successfully.

If Test #148 fails with an Error Code 2–32, see [TDM-CLK \(TDM Bus Clock\)](#) to resolve the problem. If not, continue with the following steps.

3. For Duplicated Tone-Clock circuit packs in the master PN: Switch Tone-Clock circuit packs on the master PN with `set tone-clock location`.

For Simplex Tone-Clock circuit packs in the master PN: replace the primary and secondary (if administered) DS1 Interface circuit packs.

4. Investigate any other SYNC errors.

- g. **Error Type 2049:** the ATM Expansion Interface circuit packs have errors that affect synchronization. Test the ATM Expansion Interface circuit pack with `test board location`. This error can take up to one hour to clear.
- h. **Error Types 1, 257, and 513:** noise on the DS1 line can cause transient alarms on synchronization. Therefore, when a synchronization problem occurs on Error Types 1, 257, or 513, a WARNING alarm is first raised for 15 to 20 minutes before the alarm is upgraded to a MINOR or MAJOR alarm.

Demand test descriptions and error codes

ATM-TRK (Circuit Emulation Service Circuit Pack)

MO Name in Log	Alarm Level	Initial Command to Run	Full Name of MO
ATM-TRK	MAJ MIN WRN	<code>test board location</code>	ATM TRUNK (ATM Circuit Emulation Service)

ATM-TRK explains how to test and repair TN230x ATM Interface circuit packs (TN2305 and TN2306) that have been administered as virtual ISDN-PRI trunks for ATM Circuit Emulation Service (CES). The maintenance instructions for TN230x circuit packs that have been administered as Expansion Interfaces for WAN connectivity are in [ATM-INTF \(ATM Interface\)](#)

Description

The TN2305 and TN2306 ([Table 51: ATM-TRK circuit packs](#)) are dual-purpose ATM circuit packs that can be administered as either:

- 1 [ATM Circuit Emulation Service](#) or virtual ISDN-PRI signaling trunks
- 1 Expansion Interfaces (ATM-EIs) for port-network connectivity (ATM PNC) between the PNs

Either circuit pack “personality” requires SONET OC-3 or SDH STM-1 fiber cable connections between the circuit pack and the ATM switch. As a trunk board, it supports direct connection between ATM CES circuit packs without an intervening ATM switch.

Table 51: ATM-TRK circuit packs

Circuit pack	Channel types	Interface	Fiber	Echo cancellation
TN2305	B and D-Channels	24 or 32 channel	Multimode	Y
TN2306	B and D-Channels	24 or 32 channel	Single-mode	Y

Note:

TN230x circuit packs are not interchangeable.

ATM Circuit Emulation Service

Under ATM Circuit Emulation Service (CES), simulate ISDN-PRI circuits by assigning ports to signaling groups. Each signaling group represents a PRI circuit, and the ports in the group represent the D-Channel and B-Channels of that circuit.

Virtual D-Channels

Non-facility associated signaling is not supported under ATM-CES, so you must reserve one port in each signaling group for use as a D channel. Use channel 24 when emulating a T-1 ISDN facility, and D-Channel 16 when emulating an E-1 facility. The D-Channel can be any physical port from 9 to 32.

Virtual circuits

The TN230x can support a varied number of virtual circuits, depending on the switch and the administration of the circuit pack.

Virtual trunk groups

You can bundle physical DS1 ISDN-PRI circuits and virtual ATM-CES circuits into the same trunk groups. Virtual circuits can only be assigned to all-virtual, all-ATM trunk groups.

LEDs

The ATM circuit pack LEDs give you a visual indication of the condition of the TN230x circuit pack ([Table 52: ATM-TRK LED interpretation](#)).

Table 52: ATM-TRK LED interpretation

LEDs	Condition	LED status
Red	Error (alarm logged)	On
Red & Green	Booting (LEDs being tested)	Blinking (on 200 ms, off 200 ms)
Green	Test/maintenance in progress	On
Amber	Fiber Loss of Signal (LOS), LOF, MS_RDI, MS_AIS, LCD, HP_RDI, HP_AIS, LOP, PSC	Blinking fast (100 ms on, 100 ms off)
Amber	Signal to ATM switch down	Blinking slowly (500 ms on, 500 ms off)
Amber	One or more CES signaling groups administered	On
Amber	CES signaling group not administered or not reporting to firmware	Off

ATM-TRK-related commands

[Table 53: ATM CES troubleshooting commands](#) lists some commands that can be useful in troubleshooting ATM errors and alarms.

Table 53: ATM CES troubleshooting commands

Command	Description
<code>display circuit-packs cabinet</code>	Shows the circuit packs in the cabinet, identifying ATM trunk as well as ATM-EI boards. "ATM Interface" boards have not been administered as CES or PNC.
<code>display atm ports location</code>	Shows the 256 ports on the ATM board with the corresponding signaling and trunk group.
<code>list configuration atm</code>	Lists the ATM boards, identifying equipment location, board code, type, and vintage.
<code>list configuration trunks</code>	Lists boards identifying assigned ports. While the ATM board is listed, the 256 ports are not.
<code>busyout/release atm signaling-group</code>	Busyout or release of an ATM signaling group within a trunk group.
<code>status atm signaling-group</code>	Show current status of an ATM signaling group.
<code>status trunk-group</code>	Shows status of the trunk group (ATM signaling groups are part of trunk groups).

3843 (u)					
3999(y)	Any				
					3 of 3

Notes:

- a. **Error Type 1:** the ATM-TRK circuit pack does not appear to be in its assigned slot.
 - 1. Make sure that the ATM-TRK circuit pack is installed correctly seated in the slot administered for the ATM trunk.
- b. **Error Type 18:** the ATM circuit pack is busied out.
 - 1. Run *release board location*.
- c. **Error Type 23:** an ATM trunk is administered, but the corresponding ATM-TRK circuit pack does not appear to be physically installed.
 - 1. Make sure the ATM-TRK circuit pack is installed and correctly seated in the slot.
- d. **Error Type 125:** an ATM trunk is administered but a non-ATM-TRK circuit pack is installed in the corresponding slot. You have two options:
 - 1. Replace the incorrect circuit pack with an ATM-TRK circuit pack.
 - 1. Or re-administer the slot for the circuit pack that is physically present, locate the slot where the ATM-TRK circuit pack is actually installed, and re-administer the ATM trunk.
- e. **Error Type 257:** Control Channel Looparound test (#52) failed. The circuit pack is not properly connected with the control channel on the TDM bus.
 - 1. Take the corrective action specified by [Control Channel Looparound Test \(#52\)](#).
- f. **Error Type 513:** ATM CrossTALK Test #1298 failed. The board is writing to or reading from a TDM time slot that is not allocated to the board, or the Digital Signal Processor (DSP) selected for this test has malfunctioned.
 - 1. Run *test board location*.
 - 2. Take the corrective action specified for [ATM Crosstalk Test \(#1298\)](#)
- g. **Error Type 769, 770:** the ATM switch is requesting too many LAPD retransmissions (off-board ATM cell corruption errors).

Error Type	Aux Data	Description
769	35	Excessive LAPD retransmission requests
770	25	Uncorrectable ATM cell headers – threshold

1. Check the connections between the fiber cable, the ATM-TRK circuit pack, and the ATM switch.
2. See [PKT-BUS \(Packet Bus\)](#) for test and corrective procedures.
3. Determine what type of fiber is installed between the ATM-TRK circuit pack and the ATM switch.

If	Then
There is multimode fiber	Check the length of the fiber. If the cable is longer than 2 km, it may be causing errors.
There is single-mode fiber or the length of the multimode fiber is less than 2 km	The source of the errors can lie in the ATM facility, the ATM-TRK circuit pack, or the far-end circuit pack.

4. Perform ATM loopback tests on the near-end ATM-TRK circuit pack and on the far-end circuit pack or ATM switch.

If	Then
The ATM-TRK circuit pack fails the loopback test.	The problem is in the ATM-TRK circuit pack. Replace the circuit pack.
The far-end circuit pack or ATM switch fails the loopback test.	The problem is in the far-end circuit pack or ATM switch. Consult the circuit-pack or ATM switch documentation for advice.
The equipment at each end of the ATM span passes the loopback test	The problem is somewhere in the ATM span. Lack of bandwidth can be forcing an intermediate ATM switch to drop cells.

5. Check capacity and peak bandwidth consumption for the ATM span.

If	Then
The capacity of the span is inadequate, or bandwidth consumption is too high.	Reduce traffic on the system to ensure that it is using no more than its subscribed bandwidth.

- h. **Error Type 771:** the ATM switch is sending cells with unknown Virtual Path-Identifier (VPI) and Virtual Channel-Identifier (VCI) addresses.
 1. Make sure that the ATM-TRK circuit-pack address is administered identically on the ATM switch and the S8700-series system.
- i. **Error Type 1281:** Board major signals error (loss of high-level signal). The far end has detected a major problem in transmissions originating from the ATM-TRK circuit pack. The possible Aux Data values for this software counter are listed in [Table 55: Error type 1281 Aux Data and repair procedures](#) on page 190.

Table 55: Error type 1281 Aux Data and repair procedures 1 of 3

Aux Data	Alarm Description	Repair procedure
15	SYSCLOCK failed	<p>The board is not locked to the TDM backplane clock signal. This is probably due to a Tone-Clock problem.</p> <ol style="list-style-type: none"> 1. Check for TDM-BUS or TONE-BD errors in the Error Log. 2. If no other problems are present, reset the circuit pack with reset board location
16	Loss of Signal: LOS	<p>The fiber is not connected properly to the ATM-TRK board or ATM switch (or to the multiplexer section [MUX] if present).It is possible that the board transceivers are not functioning properly.</p> <ol style="list-style-type: none"> 1. Run test board location. 2. If Test #1259 fails with Error Code 16, connect a fiber back-to-back in a looped mode (one strand of fiber connecting the transmit transceiver to the receive transceiver of the board) and see if the amber LED flash goes away. If it does the problem is off-board. 3. If the amber LED continues to flash, replace the circuit pack.
17	Loss of Frame: LOF	<p>The fiber signal cot obtain or maintain STM-1/OC-3 framing.</p> <ol style="list-style-type: none"> 1. Try to more the fiber on the ATM switch side to a different port. 2. If the problem persists, reset the circuit pack with reset board location.
18	Multiplexer Section Alarm Indication Signal: MS_AIS	<p>There is a major problem on the far end (between multiplexer section [MUX] and the switch) that prohibits the circuit pack from sending a valid signal.</p> <ol style="list-style-type: none"> 1. See if the ports at the MUX and/or the ATM switch are connected snugly. 2. Run test board location. 3. If Test #1259 fails with Error Code 18, connect a fiber back-to-back in a looped mode (one strand of fiber connecting the transmit transceiver to the receive transceiver of the board) and see if the amber LED flash goes away. 4. If it does the problem is off-board. 5. If the amber LED continues to flash, replace the circuit pack; if the error persists, escalate the problem.
1 of 3		

Table 55: Error type 1281 Aux Data and repair procedures 2 of 3

Aux Data	Alarm Description	Repair procedure
19	Multiplexer Section Remote Defect Indicator: MS_RDI	<p>The far end is detecting a major problem with the signal that this board is transmitting.</p> <ol style="list-style-type: none"> 1. Make sure the ATM switch port (or a MUX port, if present between ATM switch and the ATM-TRK board) is the same as the ATM-TRK circuit pack's cable interface 2. Run test board location. 3. If Test #1259 fails with Error Code 19, connect a fiber back-to-back in a looped mode (one strand of fiber connecting the transmit transceiver to the receive transceiver of the board) and see if the amber LED flash goes away. 4. If it does the problem is off-board. 5. If the amber LED continues to flash, replace the circuit pack; if the error persists, escalate the problem.
20	Loss of pointer: LOP	<p>ATM framer chip is unable to access the payload part of the signal.</p> <ol style="list-style-type: none"> 1. Reset the board with reset board location. 2. If the error persists replace the board.
21	Path Signal Error (PSL) (STM1/SONET)	<p>The incoming signal payload is not set up for transmission of ATM data.</p> <ol style="list-style-type: none"> 1. Make sure the ATM switch port (or a MUX port, if present between ATM switch and the ATM-TRK board) is the same as the ATM-TRK circuit pack's cable interface.
22	High-level Path Alarm Indication Signal: HP_AIS	<p>The payload is invalid.</p> <ol style="list-style-type: none"> 1. Make sure the ATM switch port (or a MUX port, if present between ATM switch and the ATM-TRK board) is the same as the ATM-TRK circuit pack's cable interface. 2. Run test board location. 3. If Test #1259 fails with Error Code 22, connect a fiber back-to-back in a looped mode (one strand of fiber connecting the transmit transceiver to the receive transceiver of the board) and see if the amber LED flash goes away. 4. If it does the problem is off-board. 5. If the amber LED continues to flash, replace the circuit pack.
		2 of 3

Table 55: Error type 1281 Aux Data and repair procedures 3 of 3

Aux Data	Alarm Description	Repair procedure
23	High-level path Remote defect Indicator: HP_RDI	<p>The far end is detecting a major problem with the signal that this board is transmitting. The transmitted payload is invalid.</p> <ol style="list-style-type: none"> 1. Make sure the ATM switch port (or a MUX port, if present between ATM switch and the ATM-TRK board) is the same as the ATM-TRK circuit pack's cable interface. 2. Run test board location. <p>If Test #1259 fails with Error Code 23, connect a fiber back-to-back in a looped mode (one strand of fiber connecting the transmit transceiver to the receive transceiver of the board) and see if the amber LED flash goes away.</p> <ul style="list-style-type: none"> 1. If it does the problem is off-board. 1. If the amber LED continues to flash, replace the circuit pack.
24	Loss of cell delineation (LCD)	<p>On board ATM framer chip is not able to frame cells based on the cell header.</p> <ol style="list-style-type: none"> 1. Reset the board with reset board location. 2. If the error persists, replace the board.
27	SIGCON_DOWN ATM switch high level signal.	<p>The board cannot communicate with the ATM switch.</p> <ol style="list-style-type: none"> 1. Busyout the board (busyout board location). 2. Test the board (test board long location). 3. If Test #1260 fails, replace the board. 4. If Test #1260 passes, make sure the ATM address on both the server and the ATM switch sides are the same for this board. 5. If the address is the same, change the port on the ATM switch side. 6. If the error is resolved, the problem is on the ATM switch port.
3 of 3		

j. **Error Type 1537:** LANHO bus timeout. The circuit pack is transmitting too many bytes on the LAN bus for a single frame. This can be due to:

- 1. an on-board fault.
- 1. a faulty data received on one of the circuit pack's external ports.

If the error occurs three times in 10 minutes, the board is isolated from the packet bus, and the board is alarmed. To clear the alarm:

1. Restore this circuit pack to the packet bus with this command sequence:
 - a. **busyout board location**
 - b. **reset board location**
 - c. **test board location long**

- d. *release board location*
- 2. If the problem persists and there are no PKT-BUS or port alarms, replace the circuit pack.
- k. **Error Type 1538:** The ATM-TRK circuit pack is hyperactive (sending an abnormal number of control messages to the processor). Use the following command sequence for this ATM-TRK circuit pack:
 - 1. *busyout board location*
 - 2. *reset board location*
 - 3. *test board location long*
 - 4. *release board location*
 - 5. If this error persists, replace the circuit pack.
- l. Error Type 1794: LANHO transmit FIFO overflow. The circuit pack's transmit buffers have overflowed.
 - 1. Run *test board location r 5*. If Test #598 fails, replace the circuit pack.
- m. **Error Type 2049:** ACL Link Failure (link is down). The ATM Control Link (ACL) has failed, communication has been interrupted between the server and the ATM-TRK circuit packs on the system, and signaling-group parameters are not communicated across the packet bus.
 - 1. Check the [PKT-BUS \(Packet Bus\)](#) and [SYS-LINK \(System Links\)](#) MOs, and follow the repair procedures indicated.
 - 2. Run *test board location* against the ATM-TRK circuit pack. If Test #598 fails, follow the repair procedures for [Packet Interface Test \(#598\)](#)
- n. **Error Type 2306:** too many parity errors in data received from the LAN/packet bus.
 - 1. Run *test board location*

If	Then
Test 598 fails.	Follow the repair procedures for Packet Interface Test (#598) .
Test 598 passes	See PKT-BUS (Packet Bus) and perform the specified repair.
There are no errors against the packet bus MO	This can be a transient condition. Do nothing now, but escalate if the error occurs repeatedly.

- o. **Error Type 2561:** Packet Interface Looparound test (#598) failure. The ATM-TRK circuit pack has failed, the packet bus has a minor alarm active, or the packet bus is out of service.

Communication Manager Maintenance Object Repair Procedures

1. Run *test board location*

If	Then
Test 598 fails	Follow the repair procedures for Packet Interface Test (#598) .
Test 598 passes	See PKT-BUS (Packet Bus) and perform the specified repair.
There are no errors against the packet bus MO	This can be a transient condition. Do nothing now, but escalate if the error occurs repeatedly.

p. **Error Type 2817, 2818:** DSP failure detected along the circuit path.

1. Run *test board location*.
2. Follow the repair procedures suggested for [ATM Board DSP Test \(#1293\)](#).

Error Type	Description
2818	One or more DSPs failed. The Aux Data field contains the ID number of DSP that failed
2817	DSP test failure. The Aux Data field contains the following information about the failed DSPs: X is the number of talker DSPs Y is the number of listener DSPs Z is the number of echo-cancelling DSPs

q. **Error Type 3330:** LANHO critical error. The circuit pack reports that the on-board LANHO chip is insane (possibly due to a problem in packet bus arbitration, in the transmission line frame, or in the circuit pack itself). The circuit pack cot talk to the packet bus.

1. Check for PKT-BUS alarms.

If	Then
There is a packet bus alarm	There is probably a packet bus problem, particularly if other circuit packs on the packet bus report the same error. See PKT-BUS (Packet Bus) and Isolating and repairing packet-bus faults in Maintenance Procedures for Avaya Aura™ Communication Manager, Media Gateways and Servers (03-300432) for repair procedures.
1 of 2	

If	Then
There are no packet bus alarms	Run the following command sequence: <code>1.busyout board location</code> <code>2.reset board location</code> <code>3.test board location long</code> <code>4.release board location</code>
The problem persists	Replace the ATM-TRK circuit pack.
2 of 2	

- r. **Error Type 3585:** Major board alarm; failure of critical components involved in the operation of the circuit pack. The circuit pack has failed, and the switch can no longer recognize it.

Aux Data	Description
1	ATM framer chip failure
2	NCE failed
4	TDM PLD failed
5	Every DSP on the circuit pack has failed.
6	RNP (Receive Network Processor) failed
7	TNP (Transmit Network Processor) failed
8	MEMORY read/write failure
9	DUART failure

1. Run `test board location long`.

If	Then
Test #1259 fails with Error Code XXYY and XX is an AUX value in the preceding table	Replace the ATM-TRK circuit pack.
The system does not recognize the circuit pack	Replace the ATM-TRK circuit pack.

- s. **Error Type 3841:** the ATM-TRK circuit pack received an unrecognized message from the switch and responded with an inconsistent down-link error message.

1. Do nothing. This error does not affect service.

Communication Manager Maintenance Object Repair Procedures

- t. **Error Type 3842:** LANHO Receive FIFO Overflow error; the packet bus is delivering data to the ATM-TRK circuit pack faster than the circuit pack can distribute it to the endpoint.
1. Do nothing. The circuit pack can recover by itself.
- u. **Error Type 3843:** The firmware on the circuit pack is reporting a resource that is too low. This error does not affect the service and no action is required.
- v. **Error Type 3999:** circuit pack sent a large number of control channel messages to the switch within a short period of time.

If	Then
Error Type 1538 is also present	The circuit pack is taken out of service.
Error Type 1538 is absent	<p>The circuit pack is not taken out of service, but has generated 50% of the messages necessary to be considered hyperactive.</p> <ol style="list-style-type: none"> 1 This can be normal during heavy traffic. 1 If the error is logged during light traffic, it can indicate a problem with the circuit pack or the equipment attached to it.

Demand test descriptions and error codes

Investigate tests in the order presented. By clearing errors associated with the first test, errors generated from other tests may also be cleared. Click on the link to see the full description of the test, error codes, and recommended actions.

ATM Crosstalk Test (#1298)		X		ND
ATM Board Reset (#1256)			X	D
				2 of 2

1. D = Destructive, ND = Nondestructive

ATT-ADJ (Avaya Adjunct)

See [BRI-SET, Various Adjuncts](#).

ATTE-AJ (Ethernet Avaya Adjunct)

See [BRI-SET, Various Adjuncts](#).

AUX-BD (Auxiliary Trunk Circuit Pack)

MO Name in Log	Alarm Level	Initial Command to Run	Full Name of MO
AUX-BD	MIN WRN	<code>test board location</code>	Auxiliary Trunk circuit pack

See [XXX-BD \(Common Port Circuit Pack/Media Module\)](#) maintenance information for circuit pack-level errors.

See [AUX-TRK \(Auxiliary Trunk\)](#) for related trunk information.

AUX-TRK (Auxiliary Trunk)

MO Name in Log	Alarm Level	Initial Command to Run	Full Name of MO
AUX-TRK	MAJ ¹ MIN	<code>test port location 1</code>	Auxiliary Trunk
	WRN	<code>test port location</code>	

1. A Major alarm on a trunk indicates that alarms on these trunks are not downgraded by **set options** and that at least 75% of the trunks in this trunk group are alarmed.

The TN763B/C/D and TN417 Auxiliary Trunk circuit packs may be used to provide ports for the following features: Music-On-Hold, loudspeaker paging (voice and coded chimes), dictation, automated wake-up with AUDICHRON. Recorder/Announcer, and recorded announcements. TN763C circuit packs support Mu-law companding. TN417 circuit packs support A-law companding. TN763D can support either companding mode and defaults to mu-law on initialization. Companding modes are administered on the **location-parameters** screen.

Use the following commands to administer the features:

Command	Administration
<code>change system-parameters features</code>	Music-On-Hold
<code>change paging loudspeaker</code>	loudspeaker paging
<code>add trunk-group grp#</code> [Customer-Provided Equipment (CPE) Type]	loudspeaker paging
<code>change paging loudspeaker</code>	system-provided paging
<code>add trunk-group grp#</code>	access to otherwise-provided (CPE) paging
<code>change paging code-calling-ids</code>	translation for code chiming
<code>add trunk-group grp# (CPE Type)</code>	Recorded announcement and dictation
<code>change system-parameters</code> <code>hospitality</code>	Automatic wake-up (uses all four ports on a TN763B Auxiliary Trunk circuit pack)

Music-On-Hold provides audible feedback to a held, parked, or otherwise split-away party indicating that the call is still connected. The feedback can be customer-provided music, a recorded message, or other audible indication. Since the Music-On-Hold port is always busy, some of its port tests always abort.

The Loudspeaker Paging feature provides voice and/or code calling chime paging. If multiple paging zones are provided at a customer's premises, the Loudspeaker Paging feature gives a user the option of paging to a particular zone or to every zone. If a zone is active for one page, it cannot be used at the same time for another.

Communication Manager Maintenance Object Repair Procedures

An Auxiliary Trunk circuit pack contains four ports and uses DTMF signaling. A different hardware interface between the switch and the auxiliary equipment is used for the four types of signaling that the auxiliary trunk circuit pack supports.

The interface used for the Communication Manager loudspeaker paging consists of the following three pairs:

- 1 The Tip-Ring (T-R) pair used for voice transmission.
- 1 The S (S-S1) pair that carries answer supervision and/or make busy information.
- 1 The SZ (SZ-SZ1) pair that provides the external equipment with a seizure indication.

The interface used for recorded announcement, dictation, and other loudspeaker paging consists of the following two pairs:

- 1 The Tip-Ring (T-R) pair used for voice transmission.
- 1 The S (S-S1) pair that carries answer supervision and/or make busy information.

The interface used for Music-On-Hold consists of one pair:

- 1 The Tip-Ring (T-R) pair used for voice transmission.

The interface, used for automatic wake-up using an Audichron recorder/announcer unit, consists of the following two pairs:

- 1 The Tip-Ring (T-R) pair used for voice transmission.
- 1 The S (S-S1) pair that carries the synchronization signal.

Error log entries and recommended actions

					2 of 2

1. Major or Minor alarms may be downgraded to Warning alarms based on the values used in **set options**.

Notes:

- a. **Error Type 0:** Run the short test sequence first. If every test passes, run the long test sequence. Refer to each appropriate test's description, and follow its recommended procedures.
- b. **Error Type 1** with **Aux Data 57481** indicates a port fault. Use an empty port if one is available until the circuit pack can be replaced.
- c. **Error Type 1** or **769** with **Aux Data 57482** indicates a fault on signaling lead, which is an off-board error. This error should only occur with loudspeaker paging. If the trunk is being used for another application, check that the administration is correct. Otherwise, check the wiring to the external equipment connected to the Auxiliary Trunk and check the external equipment.
- d. **Error Type 15:** software audit error that does not indicate any hardware malfunction. Run short test sequence, and investigate associated errors.
- e. **Error Type 130:** the circuit pack has been removed or has been insane for more than 11 minutes. To clear the error, reseal or replace the circuit pack.

AXA12-BD (AUDIX Circuit Pack)

MO Name in Log	Alarm Level	Initial Command to Run	Full Name of MO
AXA12-BD	MIN WRN	<i>test board location</i>	AUDIX circuit pack

TN568 EMBEDDED AUDIX circuit packs operating in control-link mode appear to the system as TN746 Analog Line circuit packs with vintage greater than 50.

For circuit-pack-level problems, see [XXX-BD \(Common Port Circuit Pack/Media Module\)](#).

The AUDIX system has an extensive maintenance strategy of its own that is described in *DEFINITY® AUDIX Maintenance*.

AXA12-RS (AUDIX Reserve Slots)

MO Name in Log	Alarm Level	Initial Command to Run	Full Name of MO
AXA12-RS	NONE	NONE	TN568 12-port analog reserve slot
ADX8D-RS	NONE	NONE	TN568 8-port digital reserve slot
AXD12-RS	NONE	NONE	TN568 12-port digital reserve slot

There are no tests associated with these MOs. Both **test board** and **busyout board** abort when either is attempted on a reserved slot. An error message indicates that the slot is associated with the circuit pack that the TN568 is emulating, but the requested operation is not valid. If there are errors logged against these MOs, see [XXX-BD \(Common Port Circuit Pack/ Media Module\)](#).

The TN568 circuit pack connects to the switch through a single slot in the backplane. However, the number of slots physically occupied by the circuit pack is supplied by the board when inserted. The TN568 is 2 slots wide: the functional slot and a reserve slot. The reserve (blank) slot to the left of the functional slot is a place holder on the switch and has no interaction with the switch.

These MOs are place holders for the extra slot needed for the EMBEDDED AUDIX board. Each instance of these MOs represents a reserve slot associated with the respective circuit pack mode in which the TN568 (EMBEDDED AUDIX) is working. They are used for EMBEDDED AUDIX and emulation of respective port types.

AXD12-BD (AUDIX circuit pack)

MO Name in Log	Alarm Level	Initial Command to Run	Full Name of MO
AXD12-BD	MIN WRN	<i>test board location</i>	AUDIX circuit pack

The AXD12-BD MO represents a TN568 EMBEDDED AUDIX circuit pack operating in 12-port digital (DP) mode. TN568 EMBEDDED AUDIX circuit packs operating in 12-port digital mode appear to the system as TN2181 Digital Line circuit packs with vintage greater than 50.

For circuit-pack-level problems, see [XXX-BD \(Common Port Circuit Pack/Media Module\)](#).

AXD12-RS (AUDIX Reserve Slots)

See [AXA12-RS \(AUDIX Reserve Slots\)](#).

BRI-BD (ISDN-BRI Line Circuit Pack)

MO Name in Log	Alarm Level	Initial Command to Run	Full Name of MO
BRI-BD	MAJ MIN WNR	<code>test board location 1</code>	ISDN-BRI Line circuit pack
LGATE-BD	MAJ MIN	<code>test board location 1</code>	LAN Gateway
	WRN (See Caution)	<code>test board location</code>	

CAUTION:

A detailed flowchart for isolating and resolving Packet Bus faults is included in [Isolating and repairing packet-bus faults](#) in *Maintenance Procedures for Avaya Aura™ Communication Manager, Media Gateways and Servers (03-300432)*. This flowchart, along with the other information presented in the chapter, can help in resolving problems that involve more than a single station or circuit pack. Whenever the repair procedures for this Maintenance Object refer to Packet Bus and/or Packet Control maintenance, be sure to see [Isolating and repairing packet-bus faults](#). See also [PKT-BUS \(Packet Bus\)](#) for repair procedures.

Error log entries and tests also apply to LGATE-BD.

This section relates to the TN556 ISDN BRI, TN2198 ISDN BRIU, and TN2208 LAN Gateway (LGATE) Multifunction (MFB) circuit packs.

The TN2208 LGATE MFB provides the system with the interface to Adjunct-Switch Application Interface (ASAI) and Avaya adjuncts (for example, CONVERSANT® Voice System). This circuit pack contains 12 ports for line circuit interface (although only 8 are usable by the switch), each of which operates with two B channels and one D-Channel. In this context, the term “ISDN-BRI port” is used to refer to ports on the TN2208 MFB circuit pack that are connected to ASAI or Avaya adjuncts. The TN2208 LGATE MFB is handled by the switch software as if it is an ISDN-BRI compatible board, and every maintenance action referring to ASAI and Avaya adjunct links in this section applies.

The TN556, TN2198, and TN2208 ISDN-BRI Lines are packet port circuit packs that provides access to ISDN-BRI endpoints. The ISDN-BRI Line circuit packs supports 12 ports, each of which provides access to ISDN stations. Voice and circuit-switched data from the ISDN stations are carried on the Time Division Multiplex (TDM) Bus. Signaling is carried over the packet bus.

Error log entries and recommended actions

Table 57: BRI-BD Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Recommended Action
0 (a)	0	Any	Any	Any	<i>test board location</i>

1793 (k)	46080		MIN	ON	
1794 (k)	46094		MIN	ON	
1795 (k)	46085		MIN	ON	
2306 (k)		LANBIC Receive Parity Error Counter test (#595)			
3330 (l)	46083		MIN	OFF	
3840 (m)	4096 to 4101				
3843 (n)	46097				
3999 (o)	Any			Any	

Notes:

- a. **Error Type 0:** Run the short test sequence first. If every test passes, run the long test sequence. Refer to each appropriate test's description, and follow its recommended procedures.
- b. **Error Type 1:** the circuit pack totally stopped functioning or it was physically removed from the system. The alarm is logged approximately 11 minutes after the circuit pack has been removed and/or SAKI Sanity test (#53) fails.

If the circuit pack is not in the system, insert a circuit pack (in the same slot as the error indicates) to resolve this error. Or, if the circuit pack is in the system and the red LED is on, follow the instructions for "Red (alarm)" in the Circuit Pack LEDs section of *LED Descriptions for Avaya Aura™ Communication Manager Hardware Components (03-602804)*.
- c. **Error Type 18:** This circuit pack has been busied out via `busyout board location`.
- d. **Error Type 23:** Port(s) has (have) been administered on this circuit pack but the circuit pack is not physically present.
- e. **Error Type 257:** transient communication problems between the switch and this circuit pack. Execute `test board location` and see [Control Channel Looparound Test \(#52\)](#) for the repair procedures.
- f. **Error Type 513:** An on-board hardware failure has been detected by the circuit pack.
 - Aux Data 4352:** External RAM error
 - Aux Data 4353:** Internal RAM error
 - Aux Data 4355:** ROM Checksum error
 - Aux Data 4357:** Instruction set error

Reset the circuit pack by executing `busyout board location`, `reset board location` and `release board location`. When it is reset, the circuit pack executes a set of tests to detect the presence of any of the above faults. The detection of one of these errors during initialization causes the circuit pack to lock-up and appear insane to the system. See the repair procedure in footnote (a) for Error Type 0.
- g. **Error Type 769:** reported by the circuit pack when it detects a program logic error. No action is required, but this error may lead to errors of other types being reported against this circuit pack.
- h. **Error Type 1025:** reported by the circuit pack when it cot update NPE memory and read it back. No action is required, but this error may lead to errors of other types being reported against the circuit pack.
- i. **Error Type 1293, 1294:** a critical hardware failure has been detected on the circuit pack.
 - Error Type 1293:** On-board auxiliary processor insane.
 - Error Type 1294:** Internal memory access error.

Reset the circuit pack via `busyout board location` and `reset board location`. If the [Circuit Pack Restart Test \(#594\)](#) passes, then the on-board circuitry is healthy. Retire the alarm via `test board location long clear`. If the Circuit Pack Restart test (#594) fails, replace the circuit pack.

- j. **Error Type 1537:** Frame overrun at packet bus interface. This condition may be caused by an on-board fault or by faulty data received on one of the circuit pack's external ports. If any of the ports on this circuit pack are alarmed, refer to the repair procedures for those MOs.

Error Type 1538: Circuit packet is hyperactive; that is, it is flooding the switch with messages sent over the control channel. The circuit pack is taken out-of-service when a threshold number of these errors is reported to the switch. Clear the alarm with `busyout board location`, `reset board location`, `test board location long clear`, `release board location`. If the error recurs within 10 minutes, then replace the circuit pack.

- k. **Error Type 1793, 1794, 1795, 2306:** the circuit pack is having problems transmitting data to the packet bus.

Error Type 1793: Parity errors are detected when transmitting data to the packet bus.

Error Type 1794: Overflow of packet bus transmit buffers has occurred.

Error Type 1795: Circuit pack cot find end of frame when transmitting to packet bus.

Clear the alarm via the following commands: `busyout board location`, `reset board location`, `test board location long clear`, `release board location`. If the error recurs within 10 minutes, then replace the circuit pack.

Error Type 2306: This error occurs when the circuit pack detects an error in a received frame from the packet bus. These errors are most likely caused by a packet bus problem, but may be due to a circuit pack fault. An invalid Link Access Procedure Data (LAPD) frame error occurs if the frame contains a bad cyclical redundancy check (CRC), is greater than the maximum length, or violates the link level protocol. When bus parity errors are reported, the LANBIC Receive Parity Error Counter test (#595) should be performed to determine whether the condition had cleared. See [Isolating and repairing packet-bus faults](#) in *Maintenance Procedures for Avaya Aura™ Communication Manager, Media Gateways and Servers (03-300432)* to determine whether the problem is isolated to this circuit pack or is caused by packet bus faults.

- l. **Error Type 3330:** A critical failure has been detected in the packet bus interface of the circuit pack. This failure may be due to either a packet bus or to an on-board fault. If the packet bus is alarmed, see [PKT-BUS \(Packet Bus\)](#) and [Isolating and repairing packet-bus faults](#) in *Maintenance Procedures for Avaya Aura™ Communication Manager, Media Gateways and Servers (03-300432)* for recommended repair procedures. The probability of this error being related to packet bus problems increases with the number of ISDN-BRI circuit packs displaying this error.

If the packet bus is not alarmed, reset the circuit pack with `busyout board location` and `reset board location`. If the [Circuit Pack Restart Test \(#594\)](#) passes, then the on-board circuitry is healthy. Retire the alarm with `test board location long clear`. If the Circuit Pack Restart test (#594) fails, replace the circuit pack. If the problem persists after complying with the above instructions, then follow normal escalation procedures.

- m. **Error Types 4096, 4097, 4098, 4099, 4100, 4101**: the circuit pack received a bad control channel message from the switch. Not service-affecting, no action is required. The auxiliary data identifies the error events.
- Error Type 4096**: Bad major heading
 - Error Type 4097**: Bad port number
 - Error Type 4098**: Bad data
 - Error Type 4099**: Bad sub-qualifier
 - Error Type 4100**: State inconsistency
 - Error Type 4101**: Inconsistent downlink message
- n. **Error Type 3843**: bad translation RAM detected, but call continues by using another translation location. This error is not service-affecting. No action is required.
- o. **Error Type 3999**: the circuit pack sent a large number of control channel messages to the switch in a short period of time.
- If **Error Type 1538** is also present, the circuit pack was taken out-of-service due to hyperactivity.
- If **Error Type 1538** absent, the circuit pack was not taken out-of-service, but has generated 50% of the messages necessary to be considered hyperactive. This may be normal during heavy traffic periods. If traffic is light, it may indicate a problem with the circuit pack or the equipment attached to it.

Demand test descriptions and error codes

Investigate tests in the order presented. By clearing errors associated with the first test, errors generated from other tests may also be cleared. Click on the link to see the full description of the test, error codes, and recommended actions.

1. Major alarms may be downgraded to Warning alarms based on the value used in **set options**.

Note:

The section, Isolating and repairing packet-bus faults, in *Maintenance Procedures for Avaya Aura™ Communication Manager, Media Gateways and Servers (03-300432)*, along with the other information presented in the chapter, can help resolve problems involving more than one station or circuit pack.

If a significant packet bus failure occurs, errors and alarms may not be logged as expected for BRI-PORT/ABRI-POR/ATT-PORT/ LGATE-PT/ ATTE-PT. Conditions under which this occurs are detailed in the Isolating and repairing packet-bus faults section in *Maintenance Procedures for Avaya Aura™ Communication Manager, Media Gateways and Servers (03-300432)*.

The following circuit packs/media modules support this maintenance object:

- 1 TN2208 LGATE Multifunction Board (MFB)
- 1 TN556 ISDN-BRI Line circuit pack
- 1 TN2198 ISDN-BRI Line circuit pack
- 1 MM720 BRI Media Module

The TN2208 LGATE MFB provides Communication Manager with the interface to Adjunct-Switch Application Interface (ASAI) and Avaya adjuncts (for example, CONVERSANT® Voice System). The circuit pack contains 12 ports of line circuit interface (although only 8 are usable by the switch), each of which operates with two B-Channels (referred to as B1 and B2 throughout this section) and one D-Channel. In this context, the term “ISDN-BRI port” is used to refer collectively to ports on the TN2208 circuit pack that are connected to ASAI or Avaya adjuncts.

The TN556 and TN2198 ISDN-BRI Line circuit packs provide the system with the interface to ISDN-BRI endpoints, Adjunct-Switch Application Interface (ASAI) and Avaya adjuncts (for example, CONVERSANT® Voice System). The circuit packs contain 12 ports of line circuit interface, each of which operates with two B-Channels (referred to as B1 and B2 throughout this section) and one D-Channel. In this context, the term “ISDN-BRI port” is used to refer collectively to ports on the TN556 and TN2198 circuit packs that are connected to either BRI endpoints, ASAI or Avaya adjuncts.

The MM720 BRI Media Module provides 8 S/T ISDN 2B+D ports that interface to either the central office or another PBX. The MM720 contains eight, 4-wire ports that interface to the network at the ISDN S/T reference point over two 64 Kb channels (B1 and B2) and over a 16Kb signaling (D) channel. The B1 and B2 channels can be simultaneously circuit switched, or individually packet switched. The D-channel is circuit switched. The circuit-switched connections have a Mu-law or A-law option for voice and operate as 64Kb clear data channels.

Note:

This maintenance object applies to the MM720 BRI Media Module only if its ports are all configured as station line ports instead of trunk ports.

For BRI endpoints, each B-Channel may support voice or circuit-switched data and may be circuit-switched simultaneously. The B-Channels are not used on ports connected to ASAI or Avaya adjuncts. The D-Channel is used for conveying signaling between the switch and a BRI endpoint(s), ASAI or Avaya adjunct. Each ISDN-BRI D-Channel is connected to the switch processor and the ISDN-BRI port through the packet bus.

ISDN-BRI endpoints are available in various configurations. Every endpoint requires the D-Channel to convey signaling information to the switch. Only one B-Channel is required for a voice-only set or a stand-alone data module (BRI-DAT). A voice and data-capable set requires both B-Channels (one for voice and one for data). Therefore, each TN556 or TN2198 port can support either two voice-only sets, two stand-alone data modules (BRI-DAT), or one voice and data-capable set. Only a single ASAI or Avaya adjunct may be connected to an ISDN-BRI port. Multiple adjuncts per line are not supported.

[Figure 4: ISDN-BRI Port Interactions](#) illustrates the physical connection (solid line) between an ISDN-BRI port and its associated ISDN-BRI set(s). Each physical connection allows for two B-Channels and one D-Channel. Each ISDN-BRI circuit pack can support up to 12 of these *physical* connections to different voice and voice/data sets or ASAI or Avaya adjuncts. On a TN2198 each ISDN-BRI circuit pack can support up to 12 *physical* connections to a NT1 which in turn connects to 2 terminals.

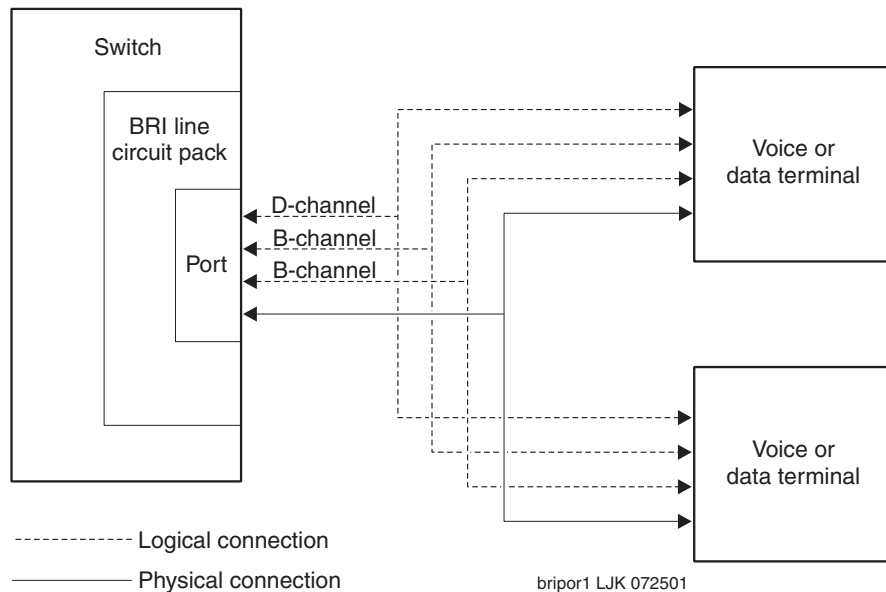

This section covers the maintenance documentation for ISDN-BRI ports. Some of the results of maintenance testing of ISDN-BRI ports may be affected by the health of the ISDN-BRI Line circuit pack (BRI-BD), BRI endpoint (BRI-SET), or ASAI adjunct (ASAI-ADJ/LGATE-ADJ/LGATE-AJ) or Avaya adjunct (ATT-ADJ/ATTE-AJ). These interactions should be kept in mind when investigating the cause of ISDN-BRI port problems. For more information about the circuit pack, see:

- 1 [BRI-BD \(ISDN-BRI Line Circuit Pack\)](#)
- 1 [BRI-SET, Various Adjuncts](#)

and for more information about its endpoints, see:

- 1 [ASAI-ADJ \(ASAI Adjunct\)](#)
- 1 [ATT-ADJ \(Avaya Adjunct\)](#)
- 1 [LGATE-AJ \(Ethernet ASAI Endpoint\)](#)

3846(o)	TEI					
3847(p)	0					

1. Major and Minor alarms on this MO may be downgraded to Warning alarms based on the value used in **set options**.

Notes:

- a. **Error Type 0:** Run the short test sequence first. If every test passes, run the long test sequence. Refer to each appropriate test's description, and follow its recommended procedures.
- b. **Error Type 1:** the Level 1 Status Inquiry fails or when the BRI circuit pack detects that Level 1 has been deactivated on the port. Refer to the repair procedures for [Level 1 Status Inquiry Test \(#621\)](#).
 - Aux Data blank:** the Level 1 Status Inquiry failed.
 - Aux Data 32773:** the BRI-LINE circuit pack detected that Level 1 has been deactivated.
- c. **Error Type 130:** the circuit pack has been removed or has been insane for more than 11 minutes. To clear the error, replace or reinsert the circuit pack.
- d. **Error Type 257:** the EPF Status Inquiry fails due to an overcurrent condition or when the BRI-LINE circuit pack detects that the EPF is in an over current condition. The aux data field contains one of the following values:
 - 1 blank – This indicates that the EPF Status Inquiry failed due to an overcurrent condition.
 - 1 40988 – This indicates that the BRI-LINE circuit pack has detected an overcurrent condition and has turned the EPF off.

Execute the short test sequence, and see the repair procedures for Test #622.

- e. **Error Type 513:** the circuit pack is having problems transmitting data to the packet bus, thus affecting the conveyance of signaling information over the D-Channel. With Aux Data 46222, this error occurs when the packet bus transmit buffers overflow. This condition probably indicates a hardware problem. The BRI-PORT Alarm Level for the error with Aux Data 46222 is "MINOR/WARNING," and the ABRI-PORT/ATT-PORT/LGATE-PT/ATTE-PT Alarm Level is "MAJOR/MINOR/WARNING." With Aux Data 0, this error occurs whenever the packet bus transmit FIFO buffers overflow. This condition can be caused by an on-board hardware problem as well as by problems on the packet bus that disrupt the BRI circuit pack's ability to transmit data onto the packet bus. Use troubleshooting procedures for both on-board hardware problems and potential off-board packet bus problems. See [PKT-BUS \(Packet Bus\)](#) as well as [Isolating and repairing packet-bus faults](#) in *Maintenance Procedures for Avaya Aura™ Communication Manager, Media Gateways and Servers (03-300432)* for more information about troubleshooting the packet bus. The BRI-PORT Alarm Level for the error with Aux Data 0 is "MINOR," and the ABRI-PORT/ATT-PORT/LGATE-PT/ATTE-PT Alarm Level is "MAJOR."
- f. **Error Type 769:** the [BRI NPE Crosstalk Test \(#617\)](#) fails. Run the long test sequence, and note the results of Test #617.
- g. **Error Type 1281:** a port's associated broadcast-signaling links have too much traffic related to link establishment. This could occur if an endpoint on this port is sending link establishment traffic on a port level broadcast link or if there are Level 1 problems on the port. Check the error logs for Level 1 errors. If Level 1 problems exist, follow the repair procedures listed for Test #621. Software will suspend activity to this port for 75 minutes when the port is alarmed due to this error (note that service suspension does not occur if

the port is an ABRI-PORT/LGATE-PT/ATTE-PT/ATT-PORT). If this problem persists, replace the endpoint or endpoints associated with this port. If replacing the endpoints does not fix the problem, follow normal escalation procedures.

- h. **Error Type 1537:** the port receives an invalid frame over the D-Channel. When CRC errors exceed five within 15 minutes, the port is taken out of service for five seconds. If five more CRC errors are received within 15 minutes of the first set of five errors, the port is taken out of service for one minute. If five more CRC errors are received within 15 minutes of the last five, the port is taken out of service for 15 minutes.

This error is most likely due to a problem with the wiring to the set or adjunct, interference on the wiring due to a noise source, or no termination (an open circuit). It usually does not indicate a problem with the circuit pack.

- 1 Check the wiring to the endpoints or the adjunct.
- 1 If the problem persists, replace the endpoints or adjuncts, or escalate the problem.

- i. **Error Type 1793:** the [BRI Port Local TDM Looparound Test \(#619\)](#) fails. Run the long test sequence, and note the results of Test #619.

There are no recommended actions for the following Error Types. The Error Types are simply provided as additional data that may prove useful while troubleshooting.

- j. **Error Type 3841:** a Layer 1 Transmission error is detected for the port. Run the long test sequence, and note the results of the [Layer 1 Transmission Error Counter Test \(#624\)](#).
- k. **Error Type 3842:** A BRI port supports up to three Terminal Endpoint Identifiers (TEIs). This error occurs when the switch receives a request for a fourth TEI on a port. Check the number of endpoints administered for this port.
- l. **Error Type 3843:** a SPID initialization request is made from an endpoint and the switch determines that the SPID value is invalid or is a duplicate of another SPID that is already initialized at Layer 3 on the port. Check the administration of the endpoints.
- m. **Error Type 3844:** the circuit pack detects an overflow of its receive buffers. Run the long test sequence, and note the results of the [Receive FIFO Error Counter Test \(#625\)](#).
- n. **Error Type 3845:** the [BRI Port Local LAN Looparound Test \(#618\)](#) fails. Run the long test sequence, and note the results of Test #618.
- o. **Error Type 3846:** most likely occurs when the Terminal Endpoint Identifier (TEI) administered for the ASAI or Avaya endpoint does not match the TEI administered in the ASAI or Avaya adjunct. Check the switch administration of the TEI against that of the adjunct and make sure that both are using the same TEI.
- p. **Error Type 384:** sets on the port do not support layer-3 initialization. Consult the Service Set documentation.

Demand test descriptions and error codes

1. The alarm level for ASAI and Avaya adjuncts may be administered using **set options**. The alarm level can be set independently for on- and off-board alarms to WARNING, MINOR, or MAJOR for every ASAI and Avaya adjunct in the system.
2. Alarming for an ASAI and Avaya adjuncts is disabled if the adjunct asks the switch to suspend maintenance. When this occurs, an error and a WARNING alarm are logged against the endpoint. Busying out and releasing the ASAI station or ADDLE station will clear the alarm.

Information for isolating and resolving packet bus faults is included in [Isolating and repairing packet-bus faults](#) in *Maintenance Procedures for Avaya Aura™ Communication Manager, Media Gateways and Servers (03-300432)*. The Troubleshooting Packet Bus Problems flowchart, along with the other information presented in the chapter, can help resolve problems that involve more than a single station or circuit pack.

If a significant packet bus failure occurs, errors and alarms may not be logged as expected for BRI-PORT/ABRI-POR/ATT-PORT/ LGATE-PT/ ATTE-PT. Conditions under which this occurs are detailed in the [Isolating and repairing packet-bus faults](#) in *Maintenance Procedures for Avaya Aura™ Communication Manager, Media Gateways and Servers (03-300432)*.

The TN2208 ESAI MFB provides the system with an Ethernet interface to Adjunct-Switch Application Interface (ASAI) and Avaya adjuncts (for example, CONVERSANT® Voice System). This circuit pack contains 8 ports of line circuit interface, each of which operates with two B-Channels (referred to as B1 and B2 throughout this section) and one D-Channel. In this

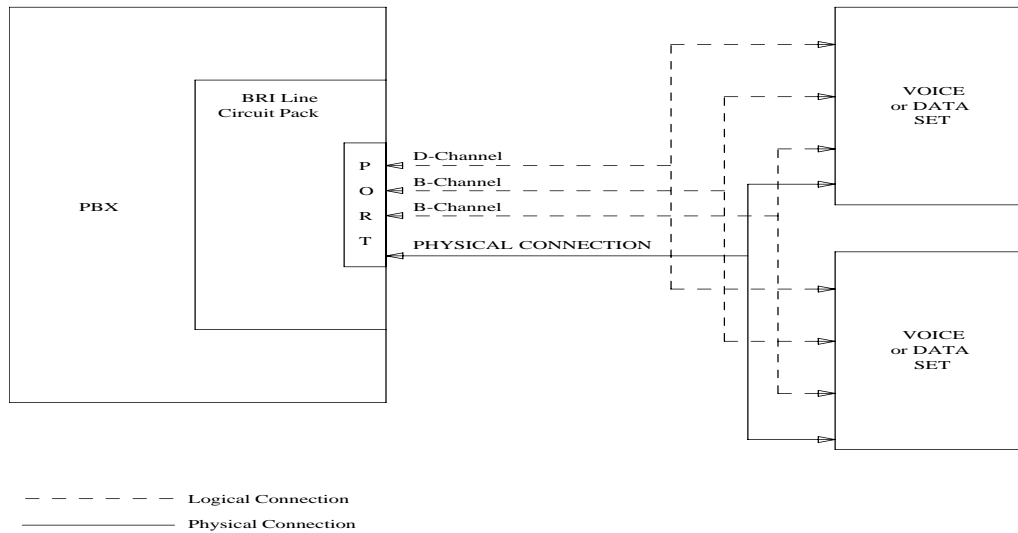

context, the term "ISDN-BRI port" is used to refer collectively to ports on the TN2208 MFB circuit pack that is connected to ASAI or Avaya adjuncts. The TN2208 ESAI MFB is handled by switch software as it is an ISDN BRI compatible board and every maintenance action referring to ASAI and Avaya Adjunct Links in this section applies.

Two types of ISDN-BRI endpoints may be connected to ISDN-BRI (ISDN Basic Rate Interface Line) TN556 and TN2198 circuit packs: ISDN-BRI station endpoints, ASAI (Adjunct-Switch Application Interface) and Avaya adjuncts (for example CONVERSANT® Voice System). These circuit packs contain 12 ports of line circuit interfaces, each of which operates at 192 kilobits per second (kbps) with two B-Channels and one D-Channel. For BRI endpoints, each B-Channel may support voice or circuit-switched data and may be circuit-switched simultaneously. The B-Channels are not used by ASAI or Avaya adjuncts. The D-Channel is used for conveying signaling between the switch and a BRI endpoint(s) or ASAI or Avaya adjuncts. Each ISDN-BRI D-Channel is connected to the switch processor and the ISDN-BRI port through the PKT-BUS (packet bus).

ISDN-BRI endpoints come in a number of configurations. Every endpoint requires the D-Channel to convey signaling information to the switch. A voice-only set requires only one B-Channel. A voice and data-capable set requires both B-Channels (one for voice and one for data). Therefore, each TN556 port can support either two voice-only sets or one voice and data-capable set. Only a single ASAI or Avaya adjunct may be connected to an ISDN-BRI port. Multiple adjuncts per line are not supported.

[Figure 5: ISDN-BRI Set Interactions](#) illustrates the physical connection (solid line) between an ISDN-BRI circuit pack and a voice or voice/data set. Each physical connection allows for two B-Channels, as stated above, plus one D-Channel. Each ISDN-BRI circuit pack can support up to 12 of these PHYSICAL connections to different voice and voice/data sets or ASAI and Avaya adjuncts.

Figure 5: ISDN-BRI Set Interactions

This section contains the ISDN-BRI Set, ASAI Adjunct and Avaya Adjunct Maintenance documentation. Some of the results of maintenance testing of the ISDN-BRI Set or the ASAI and Avaya Adjunct may be affected by the health of the ISDN-BRI circuit pack and port. These interactions should be kept in mind when investigating the cause of ISDN-BRI Set problems.

1. Major and Minor alarms for this MO may be downgraded to Warning alarms based on the value used with **set options**.

Notes:

- a. **Error Type 0:** Run the short test sequence first. If every test passes, run the long test sequence. Refer to each appropriate test's description, and follow its recommended procedures.

- b. **Error Type 2:** violations of the ISDN-BRI signaling protocol. Timers associated with certain layer-3 messages have expired before a required response was received. In the following table, the aux data field indicates what timer has just expired.

Aux Data	Timer Type
2	First T303 (SETUP timer)
3	Second T303 (SETUP timer)
4	T305 (DISConnect timer)
5	First T308 (RELease timer)
6	Second T308 (RELease timer)
10	T316 (REStart timer)
12	T309 (Layer-2 Failure timer)
16	TM100 (Management Information message Timer 1)
17	TM200 (Management Information message Timer 2)
102	TASAI (ASAI Routing timer)

The switch sent a message to the endpoint that did not respond in the allotted time. This can happen occasionally due to failure of the point-to-point signaling link or because of a problem in the BRI endpoint or ASAI adjunct or Avaya adjunct. Execute `test station extension sh` and note the results of the BRI Layer 3 Query test (#629). If this test fails, follow the repair procedure for [BRI Layer 3 Query Test \(#629\)](#).

- c. **Error Type 130:** the circuit pack has been removed or has been insane for more than 11 minutes. To clear the error, replace or reinsert the circuit pack.
- d. **Error Type 257:** the endpoint does not respond to the service state query message sent to the adjunct or the endpoint. This error causes an alarm to be raised. The alarm is retired when the switch receives a response to the service state query to the endpoint or the adjunct.

For BRI endpoints, the Aux Data field for this error contains "0." When it occurs, execute `test station extension sh` and note the results of the BRI Layer 3 Query test (#629). If this test fails, follow the repair procedure for [BRI Layer 3 Query Test \(#629\)](#)

When this error occurs for an ASAI or Avaya adjunct, the Aux Data field indicates the state of the ASAI link or Avaya link and whether an invalid response or no response was received to the query from the switch, as shown in the following table:

Aux Data	ASAI Link State	Error
102	13-restarting	No response to RESTART message
104	13-restarting	Invalid response to RESTART message
152	13-restarted	No response to layer-3 query
154	13-restarted	Invalid response to layer-3 query
202	13-established	No response to layer-3 query
204	13-established	Invalid response to layer-3 query

See the section on maintenance SAT commands in *Maintenance Commands for Avaya Aura™ Communication Manager, Media Gateways and Servers (03-300431)* for an explanation of the ASAI link states.

For ASAI or Avaya adjuncts, the switch automatically queries the adjunct every two minutes (and therefore the Layer 3 Query test is not executed for ASAI or Avaya adjuncts via a command entered from the G3MT terminal). While alarmed for this error, the switch momentarily (for five seconds) takes the associated port out-of-service every 15 minutes. This action is taken in an attempt to stimulate recovery actions to be taken by the adjunct.

When this error occurs for an ASAI or Avaya adjunct:

1. Execute **test station extension** and note tests that fail. Perform the associated repair procedures for those tests.
 2. Check the health of the adjunct by following the recommended repair procedures of the manufacturer of the adjunct if the preceding step does not resolve the problem.
 3. If the above steps do not resolve the problem and the alarm persists, follow normal escalation procedures.
- e. **Error Type 351** and associated WARNING alarm are logged against an ASAI or Avaya endpoint when the adjunct has asked the switch to suspend Maintenance on the ASAI or Avaya endpoint. Busy out and release the ASAI station or ADJLK station to clear the alarm.
- f. **Error Type 513**: the endpoint sends more messages than the switch can handle. The switch suspends the reception of messages from the endpoint for a short period of time. There is no repair procedure for this error. If the condition persists, replace the endpoint.
- g. **Error Type 769**: a BRI endpoint's signaling-associated link has too much traffic related to link establishment. This could occur if the signaling link is bouncing between assigned and established states. Software suspends activity to this endpoint for 75 minutes when the endpoint is alarmed due to this problem. Note that service suspension does not occur if the endpoint is an ASAI or Avaya adjunct. If this problem persists, replace the endpoint. If replacing the endpoint does not fix the problem, follow normal escalation procedures.

- h. **Error Type 2562-2566:** the ASAI message is not transmitted because the transmit buffer for the ASAI link is full, causing the link to be flow controlled. Frequent or persistent occurrence of these events may indicate a hardware problem or traffic overload on the signaling link, or the ASAI or Avaya adjunct. Attempt to resolve the problem by following the repair procedures issued by the manufacturer of the adjunct. If these attempts fail, the problem should be escalated because re-engineering of the traffic on the signaling link, or adjunct may be necessary.
- i. **Error 2567:** the version of ASAI is not supported, check version of the software running on the ASAI or Avaya adjunct.

Table 60: ISDN-BRI CAUSE VALUES; (BRI-SET/ASAI-ADJ Error Log Notes) 1 of 3

Error Code	Test Result	Description / Recommendation
1	Channel in use	Another station is using requested channel on the BRI-PORT. (Not applicable for ASAI or Avaya adjuncts.) For BRI endpoints: <ol style="list-style-type: none"> 1. Try to originate a call to or from this port. 2. If the error persists, busyout and release the port. 3. If the problem still persists, replace stations on the port. 4. If the problem still persists, escalate to the next tier.
34	No circuit or channel available	A resource on the switch is unavailable for a call. For BRI endpoints: This cause value is not logged. For ASAI or Avaya Adjuncts: This condition means that there are no available trunks for an outgoing call request. <ol style="list-style-type: none"> 1. Verify that the adjunct is administered to support the trunk capabilities of the switch. 2. Investigate trunk group status by entering <code>status trunk</code> commands from the SAT or by requesting a trunk group query or queries from the adjunct. 3. Perform trunk diagnostic procedures such as <code>test trunk</code>. 4. If step 3 does not resolve the problem, escalate to the next tier.
42	Switch Equipment Congestion	Switch takes control to limit received traffic. For BRI endpoints: This cause value is not logged. For ASAI or Avaya Adjuncts: <ol style="list-style-type: none"> 1. Refer to the CallVisor protocol reference manual. 2. If step 1 does not resolve the problem, escalate to the next tier.
1 of 3		

Table 60: ISDN-BRI CAUSE VALUES; (BRI-SET/ASAI-ADJ Error Log Notes) 2 of 3

Error Code	Test Result	Description / Recommendation
50	Requested Facility Not Subscribed	<p>Requested facility is implemented, but not administered. Potential administration problem with endpoint or adjunct. For BRI endpoints:</p> <ol style="list-style-type: none"> 1. Verify the switch administration of endpoint using display station or display data-module. 2. If step 1 does not resolve the problem, refer to the endpoint's service manual and verify administration on the endpoint. 3. If step 2 does not resolve the problem, escalate to the next tier. <p>For ASAI adjuncts:</p> <ol style="list-style-type: none"> 1. Display the Customer Optional Features screen (administration screen) on the switch to determine which ASAI capabilities are turned on in the switch. 2. Verify that the adjunct is administered to support the identical capabilities as the switch. If there is a mismatch in the administered capabilities, then re-administer the switch and/or the adjunct to establish a consistent set of desired capabilities on both the switch and the adjunct. 3. If step 2 does not resolve the problem, escalate to the next tier. <p>For Avaya adjuncts:</p> <ol style="list-style-type: none"> 1. Display the Customer Optional Features screen (administration screen) on the switch to determine whether the Avaya adjunct is set enabled on in the switch. 2. If Error Type 2567 or 2568, verify the Avaya adjunct version, and re-administer if needed. 3. If step 2 does not fix the problem, escalate to the next tier of support
58	Bearer Capability Not Currently Available	Requested bearer capability is implemented, but not administered. No B-Channel is administered. See recommendation for Error Code 50 above.
65	Bearer Service Not Implemented	Requested service not implemented in switch or endpoint.
69	Requested Facility Not Implemented	<p>Requested service not supported in switch or endpoint.</p> <ol style="list-style-type: none"> 1. Consult switch and endpoint documentation to determine service support. 2. If step 1 does not resolve the problem, escalate to the next tier.
2 of 3		

Table 60: ISDN-BRI CAUSE VALUES; (BRI-SET/ASAI-ADJ Error Log Notes) 3 of 3

Error Code	Test Result	Description / Recommendation
81	Invalid CRV	An invalid CRV was sent by the adjunct. 1. This may indicate a CRV inconsistency between the switch and the adjunct. Refer to the CallVisor protocol reference manual. 2. If step 1 does not resolve the problem, escalate to the next tier.
3 of 3		

- j. **Error 2568:** the adjunct ID is invalid, check the vender ID or software running on the Avaya adjunct
- k. **Error Type 2817:** there is a layer-2 problem over the D-Channel between the switch and the endpoint. When this error occurs, an alarm is raised against the station or adjunct. Execute `test station extension short` and note the results of the BRI XID test (#628). If this test fails, follow the repair procedure for [BRI XID Test \(#628\)](#).
- l. **Error Type 3073:** there is a problem with the B-Channel connection between the switch and the endpoint. When this error occurs, a warning alarm is raised against the endpoint. Execute `test station extension long` and note the results of the BRI Remote Loopback Test (#627). If this test fails, follow the repair procedure for [BRI Remote Loopback Test \(#627\)](#).
- m. **Error Type 3329:** occurs whenever the point-to-point signaling link to the endpoint goes down (except when it goes down because either the PKT-BUS has failed or has been busied out by system technician). When this error occurs, an alarm is raised against the endpoint or adjunct. Execute `test station extension short` and note the results of the Signaling Link Status test (#626). If this test fails, follow the repair procedure for [Signaling Link Status Test \(#626\)](#). The alarm is retired when the signaling link is reestablished to the endpoint or adjunct.
- n. **Error Type 3584-3839:** Certain ASAI protocol-specific cause codes are logged by switch software. The cause code can be determined from the following formula:
 - If the Error Type is greater than 3712, then the ASAI cause code is equal to the Error Type minus 3712. This code was sent to the adjunct by the switch.
 - If the Error Type is less than 3712, then the ASAI cause code is equal to the Error Type minus 3584. This code was sent to the switch by the adjunct.

A description of the various ASAI cause values is contained in the [Table 61: ASAI CAUSE VALUES; \(BRI-SET/ASAI-ADJ Error Log Entries Notes\)](#). This table also contains recommended actions associated with the cause value. In addition, the Aux Data field of the Error Log entry contains additional diagnostic information additional diagnostic.

Table 61: ASAI CAUSE VALUES; (BRI-SET/ASAI-ADJ Error Log Entries Notes)

Error Code	Test Result	Description / Recommendation
0	Unrecognized ASAI Protocol Operation	<p>Requested ASAI protocol operation is not implemented by the switch or adjunct. Aux Data field of Error Log entry contains protocol identifier for unrecognized operation.</p> <ol style="list-style-type: none"> 1. Consult switch and adjunct documentation to determine which set of operations is supported by the switch and the adjunct. Adjunct administration turning off operations not implemented by the switch may resolve the problem. 2. If step 1 does not resolve the problem, escalate to the next tier.
40	Resources not available	<p>No available internal resources to service switch or adjunct request. System transaction capacity for adjunct or switch is exceeded.</p> <ol style="list-style-type: none"> 1. Re-engineering of adjunct services may be required. If problem persists, escalate problem to the next tier.
63	SERVICE OR OPTION NOT AVAILABLE	<p>Requested ASAI capability or resource is not available on the switch or adjunct. More than one adjunct may be contending for the same switch resources. Potential administration mismatch between the resource domains administered on the switch and those administered on the adjunct.</p> <ol style="list-style-type: none"> 1. Verify that no overlapping administration of switch resources (e.g., requesting notifications on a single domain by multiple adjuncts or multiple adjuncts attempting to control a single call) exists across any adjunct connected to the switch. If an overlap exists, then re-administer the adjuncts to guarantee that each adjunct is associated with a unique set of switch resources. 2. If step 1 does not resolve the problem, escalate to the next tier.
79	SERVICE OR OPTION NOT IMPLEMENTED	<p>Requested service or option (or combination of selected options) is not supported (implemented) in switch or the adjunct.</p> <ol style="list-style-type: none"> 1. Consult switch and adjunct documentation to determine ASAI service and options supported by both switch and adjunct. Re-administration of the switch-administered capabilities (see Customer Optional Feature screen) or those of the adjunct may be necessary to correct the problem. 2. If step 1 does not provide the set of desired services due to deficient implementation, escalate the problem to the next tier.
87	Internal switch audit	<p>There is an inconsistency in switch data records.</p> <ol style="list-style-type: none"> 1. There is no action needed since the switch has corrected the data inconsistency. 2. If a number of these errors continue to occur, then escalate to next tier.

- o. **Error Type 3840-4095:** Certain ISDN-BRI cause codes are logged by switch software. The cause code can be determined from the following formula:
- If the Error Type is greater than 3968, then the ISDN-BRI cause code is equal to the Error Type minus 3968. This code was sent to the endpoint by the switch.
- If the Error Type is less than 3968, then the ISDN-BRI cause code is equal to the Error Type minus 3840. This code was sent to the switch by the endpoint.
- A description of the various ISDN-BRI cause values is contained in [Table 60: ISDN-BRI CAUSE VALUES; \(BRI-SET/ASAI-ADJ Error Log Notes\)](#). This table also contains recommended actions associated with the cause value. In addition, the Aux Data field of the Error Log entry contains additional diagnostic information.
- p. **Error 3847:** sets on the port do not support level 3 initialization. Consult the set service documentation.

Demand test descriptions and error codes

Investigate tests in the order presented. By clearing errors associated with the first test, errors generated from other tests may also be cleared. Click on the link to see the full description of the test, error codes, and recommended actions.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND ¹
Signaling Link Status Test (#626)	X	X	ND
BRI XID Test (#628)	X	X	ND
BRI Layer 3 Query Test (#629)	X(<u>a</u>)	X(<u>a</u>)	ND
BRI Remote Loopback Test (#627)		X(<u>a</u>)	ND
BRI Set Audits Test (#630)	X(<u>a</u>)	X(<u>a</u>)	ND

1. D = Destructive; ND = Nondestructive

Note:

- a. Execute `test port long location`, and review the results of the [BRI Port Local LAN Looparound Test \(#618\)](#) to verify the repair.

SPID Facility Test

This test verifies the wiring and operation of the signaling link between the switch and a endpoint or adjunct on a BRI interface. This test is not executed from the administration terminal, but rather is executed by using a BRI test set equipped with a display. The test set may replace the BRI set, ASAI or Avaya adjunct under test by plugging it into the same jack or by bridging it onto the wiring at some point between the switch and the endpoint (or adjunct), thereby creating a pseudo-BRI multipoint configuration.

When plugged into the port in this mer, the test set establishes a signaling link connection with the switch and attempts to complete Service Profile IDentifier (SPID) initialization by using the Service SPID administered for the system (see the System Maintenance Administration screen). If the test set displays the correct administered port address for the endpoint or adjunct under test, the test passes (see [Table 63: Service SPID Display](#)). If after one minute nothing is displayed on the test set, the test fails.

Table 62: SPID Facility Test 1 of 2

Test Result	Description / Recommendation
FAIL	No response is received from the endpoint. <ol style="list-style-type: none"> 1. Check the physical wiring between the switch and the endpoint or adjunct. 2. If test continues to fail, escalate the problem.
FAIL	Display does not match administered port address for the endpoint or adjunct. <ol style="list-style-type: none"> 1. Change station administration for endpoint or adjunct to match displayed port address. 2. If test continues to fail, escalate the problem.
1 of 2	

Table 62: SPID Facility Test 2 of 2

Test Result	Description / Recommendation
PASS	Display matches administered port address for the endpoint or adjunct. For BRI endpoints: <ol style="list-style-type: none">1. Verify that the SPID values administered in the switch and the endpoint are consistent.2. If the SPID values are correct, replace the endpoint.3. If test continues to fail, escalate the problem. For ASAI adjuncts: <ol style="list-style-type: none">1. Verify that the TEI values administered in the switch and the adjunct are consistent.2. If the TEI values are correct, consult the recommended repair procedures of the manufacturer for the adjunct.3. If test continues to fail, escalate the problem.

2 of 2

The abbreviations used in Service SPID Display have the following meanings:

- UU Universal cabinet number (1 – 44 for PNs)
- C Carrier (A,B,C,...)
- SS Slot (01, 02,...)
- pp port (01 – 12)
- ext extension one and two (1 – 99999)
- SPID service profile identifier

CAB-CALM (Customer alarm)

G650

MO Name in Log	Alarm Level	Initial Command to Run	Full name of MO
CAB-CALM		<code>test customer-alarm location</code>	Customer Alarm

CAB-CALM provides control of a relay contact between a pair of leads from the TN2312BP IPSI that can be wired to an external alarming device that is provided by the customer (CPAD). A contact closure is provided between the leads when the alarm exceeds the level specified in the **CPE Alarm Activation Level** field on the **change system-parameters maintenance** screen.

CAB-CALM is not associated with any background or demand tests that are used to clear alarms. CAB-CALM becomes active when any other MO reaches a predetermined level (none, warning, minor, or major) and generates an alarm. Clear the MO that is generating the alarm to retire the contact closure across the CPAD relay contact.

If you think that there is a problem with the CPAD, you can test it by executing the `test customer-alarm` command that activates the device closing the relay on the TN2312BP IPSI for one minute. You can specify the repeat parameter to close the relay contact for a longer time. The number of repeats that you specify is the number of minutes the external device is activated.

Demand test descriptions and error codes

The `test customer-alarm location (short|long) repeat #` command causes the TN2312BP IPSI to:

- 1 Close the CPAD relay contact for one minute
- 1 Return to the state determined by the active alarm level specified by the **CPE Alarm Activation Level** field on the **change system-parameters maintenance** screen

Order of investigation	Short test sequence	Long test sequence	D/ND
Customer-Provided Alarming Device Test (#115)	X	X	Nondestructive

CAB-EXFR (Emergency Transfer)

G650

MO Name in Log	Alarm Level	Initial command to run	Full name of MO
CAB-EXFR	MIN	<code>test environment location</code>	Emergency Transfer
	MAJ	<code>test environment location 1</code>	

The emergency transfer feature connects some central office trunks directly through to analog user stations when the system has a serious problem or experiences a total power failure.

Emergency transfer is activated by the TN2312BP IPSI when:

- 1 The system is booting.
- 1 The cabinet containing the TN2312BP IPSI board is in power failure.
- 1 The TN2312BP IPSI has detected a loss of control connectivity for more than 70 seconds.
- 1 The server has detected a serious problem in the cabinet.
- 1 A request is made from a SAT command to set the state of emergency transfer.

Refer to [Figure 66: G650 Cabinet Environmental Hardware Components](#) for further information.

On, off, and auto in emergency transfer

This is introduced to set the state of emergency transfer (`set emergency-xfr on | off | auto location`), because a physical switch is not provided on the faceplate of the TN2312BP IPSI circuit pack to control the state of emergency transfer.

The TN2312BP IPSI supplies -48V DC voltage to an emergency transfer panel. This -48V supply keeps relays within the emergency transfer panel operating which, in turn, keep analog stations and CO trunks wired to ports (station and trunk respectively) on the system. When the TN2312BP IPSI is supplying -48V, the state of emergency transfer is off. When a problem is detected and the TN2312BP IPSI stops supplying -48V the state of emergency transfer is on. When the TN2312BP IPSI is in the auto state, it is usually supplying -48V to the emergency transfer panel, but automatically switches to the on state and stops supplying -48V if it detects a problem.

Error log entries and recommended actions

Table 64: CAB-EXFR Error Log Entries

Error Type	Aux Data	Associated test	Alarm Level	On/Off Board	Recommended Action
1 (a)		Emergency transfer query test (#1532)	MAJ	On	<i>test environment location</i>
2 (b)		Emergency transfer query test (#1532)	MAJ	On	<i>test environment location</i>
257 (c)		Emergency transfer query test (#1532)	WRN	On	<i>test environment location</i>

Notes:

- a. **Error Type 1** – Manual on. Run *test environment location* and follow the repair steps for [Emergency Transfer Query Test \(#1532\)](#).
- b. **Error Type 2** – Firmware has activated emergency transfer. This error is not expected. Run *test environment location* and follow the repair steps for [Emergency Transfer Query Test \(#1532\)](#).
- c. **Error Type 257** – Manual off. Run *test environment location* and follow the repair steps for [Emergency Transfer Query Test \(#1532\)](#).

Demand test descriptions and error codes

Order of investigation	Short test sequence	Long test sequence	D/ND
Emergency Transfer Query Test (#1532)	X	X	Nondestructive

CAB-MTCE (Media Gateway Maintenance)

G650

MO Name in Log	Alarm Level	Initial command to run	Full name of MO
CAB-MTCE	MIN	<code>test maintenance location</code>	Media Gateway Maintenance
	MAJ	<code>test maintenance location 1</code>	

The CAB-MTCE MO is used for the alarming and logging of environmental maintenance errors for the TN2312BP IPSI in a G650 media gateway. Since the TN2312BP IPSI supports environmental maintenance in the G650 media gateway, trouble with the TN2312BP IPSI may cause environmental maintenance to falsely report problems. The following environmental MOs may be affected:

- 1 [CAB-EXFR \(Emergency Transfer\)](#)
- 1 [CAB-CALM \(Customer alarm\)](#)
- 1 [CAB-PFL \(Power Fan Lead\)](#)
- 1 [SER-BUS \(Serial Communication Bus\)](#)
- 1 [EXT-DEV \(External Device Alarm\)](#)

When the TN2312BP is used in the SCC1 and MCC1 media gateways, the TN775D Maintenance circuit pack performs environmental maintenance.

When the TN2312BP IPSI is used in a G600 or CMC1 media gateway, it monitors environment maintenance (power supply and fans) using the AuxSig lead.

Error log entries and recommended actions

Table 65: CAB-MTCE Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Recommended Action
1 (a)		Correct Board Test (#1546)	MIN	ON	<code>test maintenance location</code>
257 (b)		Sanity Test (#1547)	MIN	ON	<code>test maintenance location</code>
513 (c)	Any	All			
769 (d)	Any	All			

Table 65: CAB-MTCE Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Recommended Action
1025 (e)		Reset Test (#1545)	MIN	ON	<i>test maintenance location</i>
1281 (f)		Environmental Maintenance Initialization Test (#1548)	MIN	ON	<i>reset maintenance location</i>

Notes:

- a. **Error Type 1**—When a TN2312AP IPSI is inserted into a CMC1 or G650 Media Gateway, a minor alarm is raised. Full environmental maintenance is NOT available. Replace the TN2312AP IPSI with a TN2312BP IPSI. NOTE: A TN2312AP inserted in a G600 media gateway does NOT raise any alarm or error.
- b. **Error Type 257**—The test is unable to communicate with the TN2312BP IPSI board. NOTE: The board must be a TN2312BP IPSI for this test to run.
- c. **Error Type 513**—The TN2312BP sent a message with an unknown op-code in response to the test. The unknown op-code is recorded under Aux Data.
- d. **Error Type 769**—The TN2312BP sent a message with a valid op-code but some other part of the message was indecipherable. The op-code with the error is recorded under Aux Data.
- e. **Error Type 1025**—An attempt to reset environmental maintenance was unsuccessful.
- f. **Error Type 1281**—Environmental initialization failed. Run the [Reset Environmental Maintenance Test \(#1545\)](#), which calls the [Environmental Maintenance Initialization Test \(#1548\)](#).

Demand test descriptions and error codes

Investigate tests in the order presented. By clearing errors associated with the first test, errors generated from other tests may also be cleared. Click on the link to see the full description of the test, error codes, and recommended actions.

Order of investigation	Short test sequence	Long test sequence	D/ND ¹

Sanity Test (#1547)	X	X	ND
Reset Environmental Maintenance Test (#1545)		X	D

1. D = Destructive, ND = Nondestructive

CAB-PFL (Power Fan Lead)

G650

MO Name in Log	Alarm Level	Initial command to run	Full name of MO
CAB-PFL	MAJ MIN	<code>test environment location</code>	Power Fan Lead

The CAB-PFL represents the state of a combined power/fan lead. This lead is known as the AuxSig lead. On a G650, the AuxSig output signal is a ground referenced relay contact closure indicating a failure of the 655A power supply outputs, hot spot thermal warning, hot spot thermal shutdown, or failure of the fan assembly in a G650.

Use the AuxSig lead to determine the alarm state of the power supplies and fans if the serial bus or the interface to the serial bus of the TN2312BP IPSI in a G650 fails. If there is a CAB-PFL alarm in a G650 carrier, there should also be a SER-BUS, POW-SUP, CAB-TEMP, or PS-RGEN alarm indicating the source of the failure.

Refer to [Figure 66: G650 Cabinet Environmental Hardware Components](#) for further information.

When the TN2312BP IPSI is used in a CMC1 or a G600 carrier, use the CAB-PFL MO to determine the status of the power supply and fans, but use the repair procedure for [RMC-ENV \(Power/Fan Sensors\)](#).

Fan/filter replacement procedures for the CMC1 and G600 media gateways are found under [Variable-speed fans](#) in *Maintenance Procedures for Avaya Aura™ Communication Manager, Media Gateways and Servers (03-300432)*.

Error log entries and recommended actions

Table 66: CAB-PFL Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level ¹	On/Off Board	Recommended Action
1 (a)		Power/Fan Lead Query Test (#1533)	MAJ MIN	OFF	<code>test environment location</code>

1. The alarm level of CAB-PFL is adjusted to be the same as the highest active alarm level for SER-BUS, POW-SUP, CAB-TEMP, or PS-RGEN, or it will be a MAJOR alarm if no G650 alarms in that category are found.

Note:

- a. **Error Type 1:** The AuxSig lead is active. Run `test environment location` and follow the repair steps for [Power/Fan Lead Query Test \(#1533\)](#).

Demand test descriptions and error codes

Order of Investigation	Short test sequence	Long test sequence	D/ND
Power/Fan Lead Query Test (#1533)	X	X	Nondestructive

CAB-TEMP (Cabinet Temperature)

G650

MO Name in Log	Alarm Level	Initial Command to Run	Full name of MO
CAB-TEMP	MAJ MIN	<code>test board location</code>	Cabinet Temperature

CAB-TEMP monitors the G650 and the 655A for the following:

- 1 The power supply
 - Inlet temperature
 - Hot spot temperature status
 - Fan speed
 - Fan alarm lead
- 1 The G650 carrier exhaust temperature

The serial bus is used by the TN2312BP IPSI to obtain this information from each power supply in a G650 media gateway. There is only one outlet temperature sensor and fan assembly in a G650, so information obtained from dual power supplies (slot 0 and 15) is redundant.

Refer to [Figure 66: G650 Cabinet Environmental Hardware Components](#) for further information.

Note:

Fan/filter replacement procedures for the CMC1 and G600 media gateways are to be found under [Variable-speed fans](#) in *Maintenance Procedures for Avaya Aura™ Communication Manager, Media Gateways and Servers (03-300432)*.

Error log entries and recommended actions

Table 67: CAB-TEMP Error Log Entries 2 of 2

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Recommended Action
513 (c)		Power supply temperature test (#1538)	MIN MAJ ¹	ON	test enviroment location test board location
769 (d)		Power supply fan test (#1538)	MIN	ON	test enviroment location test board location
					2 of 2

1. This is a minor alarm if there is a redundant power supply, and a major alarm if there is only one power supply.

Notes

- a. **Error Type 1:** the inlet temperature is over the threshold—120° Fahrenheit (49° Celsius). Run **test board** and check the results of the [Power Supply Temperature Test \(#1537\)](#).
- b. **Error Type 257:** the exhaust temperature is over the threshold—120° Fahrenheit (49° Celsius). Run **test board** and check the results of the [Power Supply Temperature Test \(#1537\)](#).
- c. **Error Type 513:** the hot spot temperature is over the threshold. Run **test board** and check the results of the [Power Supply Temperature Test \(#1537\)](#).
- d. **Error Type 769:** the fan alarm is active. Run **test board** and check results of the [Power Supply Temperature Test \(#1537\)](#).

Power Supply Fan Test (#1538)	X	X	Nondestructive

CABINET (Cabinet Sensors)

S8700 Series | S8500 | G600

MO Name in Log	Alarm Level	Initial Command to Run	Full Name of MO
CABINET	MAJ MIN	<code>test environment location</code>	Cabinet Sensors

This maintenance object covers environmental maintenance for S8700-series servers and S8500 servers equipped with multicarrier cabinets (MCCs), and for servers equipped with CMC1 or G600 carriers.

S8700 Series | S8500

Note:

The CABINET MO for S8700-series servers and S8500 servers is valid only for multicarrier cabinets (MCCs). For information about environmental maintenance on single-carrier cabinets (SCCs), see [DC-POWER \(Single-Carrier Cabinet Environment\)](#).

The cabinet sensors monitor cabinet temperature and fan rotation. Variable-speed fans are used extensively in S8700-series systems.

The Maintenance circuit pack in an MCC PN monitors a temperature sensor (S1) at the top of the cabinet and generates a major alarm if the exit air temperature exceeds 65 degrees Celsius (149 degrees Fahrenheit). Another temperature sensor in the top of the cabinet (S2) also monitors exit air temperature. If it exceeds 70 degrees Celsius (158 degrees Fahrenheit), the power-distribution unit turns off all cabinet power and invokes emergency transfer. Other sensors monitor fan performance.

The repair procedures that follow rely on your ability to distinguish between high and low fan speeds by the sound of the fans. Experience will allow you to distinguish between the high and low pitches generated by high and low speeds. A thermometer is also required for some of the procedures that follow.

In making replacements, observe the following rules:

- 1 New fan assemblies accept *only* variable-speed fans.
 - 1 Old fan assemblies accept either variable- or constant-speed fans.
 - 1 Replace a fan assembly (carrier) *only* with a fan assembly of the same type (new for new, old for old).
-

Variable-Speed Fans

A variable-speed fan is identified by the following features:

- 1 A fan and air filter assembly with product code ED-67077-30, Group 4 or greater, labeled on the front of the carrier
- 1 A 5-pin white connector mounted next to each fan on the fan assembly cover plate for speed control and alarm circuitry
- 1 A 2-pin black -48 V power connector to each fan
- 1 A power filter (ED-1E554-30, G1 or G2) located in a metal box mounted behind the fans on the right-hand cable trough as you face the rear of the cabinet
- 1 The AHD1 circuit pack and the two S4 sensors used with older fan assemblies are absent.

Alarm leads from each fan are tied together into a single lead that registers a minor alarm against CABINET whenever a fan's speed drops below a preset limit or fails altogether.

Note:

The front fans may run at a different speed than the rear fans since they are controlled by different sensors.

Note:

Fan/filter replacement procedures for the CMC1 and G600 media gateways are to be found under [Variable-speed fans Maintenance Procedures for Avaya Aura™ Communication Manager, Media Gateways and Servers \(03-300432\)](#).

Error log entries and recommended actions

[S8700 Series](#) | [S8500](#)

Table 68: S8700 Series | S8500: Cabinet Sensors Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Recommended Action
0	0	Any	Any	Any	<code>test environment location</code>
1	0 or 1	Cabinet Temperature Query (#122)	MIN	ON	<code>test environment location r 3</code>
257	0 or 1	Cabinet Temperature Query (#122)	MAJ	ON	<code>test environment location r 3</code>

CMC1

Table 69: CMC1: Cabinet sensors error log entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Recommended Action
0 (a)	0	Any	Any	Any	test environment
1(b) 257 (c) 513 (d) 769 (e) 1025 (f) 1281 (g) 1537 (h) 1793 (i)	Any	Cabinet Temperature Query Test (#122)	MAJ	ON	test environment

Notes:

- a. **Error Type 0:** Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.
- b. **Error Type 1:** the Power/Fan Status lead indicates that the power supply of one or more CMC1 cabinets has detected an alarm condition. The condition can be caused by the failure of any fan or the failure of any power supply output. If more than one CMC1 cabinet exists, all of the Power/Fan Status leads are tied together (the fan and power lead is an O-ring of all cabinets' status leads). Since an error condition on a fan or power supply output could be the result of a temporary overload (e.g. during board insertion) or caused by the location of the equipment (e.g. fan blockage), a single event may be an anomaly that eventually clears. However, a repeating condition will cause a major alarm.
- c. **Error Type 257:** temperature Sensor 1: Since temperature alarms can be transient, a single event may be an anomaly that eventually clears. However, a repeating condition will cause a major alarm and may indicate a need to replace one or more components (e.g. a Cabinet Fan may be bad, or check to see if the equipment room air conditioning supply/unit is functional).
- d. **Error Type 513:** temperature Sensor 2: Since temperature alarms can be transient a single event may be an anomaly that eventually clears. However, a repeating condition will cause a major alarm and may indicate a need to replace one or more components (e.g. a Cabinet Fan may be bad, or check to see if the equipment room air conditioning supply/unit is functional).

Note:

An out-of-tolerance voltage condition may be caused by transient conditions (e.g. board insertion or electrical noise). Voltage problems can cause serious damage to the TN2314 or highly unpredictable failure modes. Therefore, a repeating condition will cause a major alarm. The following Error Types 769 through 1793 represents the various system voltages and are listed below:

- e. **Error Type 769:** Out-Of-Tolerance voltage condition for -48 VDC.
 - f. **Error Type: 1025:** Out-Of-Tolerance voltage condition for -5 VDC.
 - g. **Error Type: 1281:** Out-Of-Tolerance voltage condition for +5 VDC.
 - h. **Error Type: 1537:** Out-Of-Tolerance voltage condition for +12 VDC.
 - i. **Error Type: 1793:** Out-Of-Tolerance voltage condition for +3.3 VDC.

CARR-POW (Carrier Power Supply)

MO Name in Log	Alarm Level	Initial Command to Run	Full Name of MO
CARR-POW	MAJ	<code>recycle carrier location</code>	Carrier Port Power Supply

Single-carrier and multicarrier cabinet types can be powered by either AC or DC external power source. Environmental maintenance differs according to cabinet type and external power supply.

 **CAUTION:**

Before powering down a cabinet or carrier that contains EMBEDDED AUDIX circuit packs (TN566), first power down the AUDIX unit to avoid damaging the AUDIX software. Instructions for powering down this unit are in the [Removing and restoring power on the CM Messaging system](#) in [Chapter 4: General troubleshooting](#) in *Maintenance Procedures for Avaya Aura™ Communication Manager, Media Gateways and Servers (03-300432)*, and in *DEFINITY® AUDIX Maintenance*.

The CARR-POW MO represents the pair of power supplies that supply +5V, -48V and -5 VDC power to each carrier in a multicarrier cabinet. In AC-powered cabinets, these are called Off Line Switches (OLS). In DC-powered cabinets, they are DC/DC converters.

Cycling Power Supplies

When a port carrier power supply problem is reported by hardware, the system can cycle the power supplies in that carrier. When a carrier is cycled, the power supplies are turned off for 2 seconds and then turned back on. The system can cycle the power supplies on any of the following types carriers even if they are duplicated:

- 1 Expansion control carrier
- 1 Switch node carrier
- 1 Single-carrier cabinet

When port carrier power is cycled, all service dependent upon circuit packs in that carrier is disrupted.

Table 70: Carrier Port Power Supplies for Multicarrier Cabinets

Code	System Power	Output (VDC)	Location
631DA	AC	+5	Left side
631DB	AC	-48/-5	Right side
644A	DC	+5	Left side
645B	DC	-48/-5	Right Side
TN755B		165	Slots 17 and 18
631WA/AR	AC	+5	Left side
631WB/BR	AC	-48	Right side
TN736	AC	-5	Used with 631
TN752	AC	165/-5	WA/WB or AR/AB
649A	AC	-48 at 10 Amps +5 VDC and -5 VDC at 6 Amps	Right side on control and port carriers. Left and right side on switch node carriers.

AC-Powered Cabinets

AC Power-Distribution Unit and Battery Charger (J58890CE-2)

[Figure 6: AC Power-Distribution Unit \(J58890CE-2\): Front](#) shows an AC power-distribution unit (List 9 or List 10). This unit sits at the bottom of some multicarrier cabinets.

Figure 6: AC Power-Distribution Unit (J58890CE-2): Front

The AC power-distribution unit contains the following components:

- 1 Circuit breaker
- 1 Electromagnetic Interference (EMI) filter
- 1 Ring generator
- 1 AC input fuse
- 1 20-Amp fuses
- 1 Signal connector
- 1 -48 VDC fan power

The optional battery charger (List 11) sits at the bottom of some multicarrier cabinets. See [Figure 7: Battery Charger \(Optional Part of J58890CE-2\): Front](#).

Figure 7: Battery Charger (Optional Part of J58890CE-2): Front

The charger is used only without an uninterruptible power supply (UPS). The charger contains:

- 1 Three 48 VDC batteries for backup power to the cabinet
- 1 A DC power relay to automatically switch the batteries into the power circuit if a main power failure is detected

[Figure 8: AC Power Distribution in Multicarrier Cabinets](#) shows AC power distribution in some multicarrier cabinets. The DC power-distribution cables are on both sides of the cabinet. **These cables supply power to each of the carriers.** The optional battery charger is at the right side of the power-distribution unit.

Figure 8: AC Power Distribution in Multicarrier Cabinets

Power Backup

If AC power fails, three 48-V DC batteries power the system for:

- 1 15 seconds in a PN cabinet
- 1 10 minutes in the expansion control carrier in the "A" position of a PN cabinet

Uninterruptible Power Supply

An external UPS provides a longer backup time than holdover batteries and can replace the batteries and battery charger. The unit connects from the AC power source to a cabinet's AC power cord. If AC power fails, the unit supplies its own AC power to the cabinet.

J58890CH-1

In AC-powered cabinets, the power-distribution unit (J58890CH-1), distributes 170 to 264 VAC from a wall outlet to a set of BU3200A Battery Interface Units (BIU). See [Figure 9: AC Power-Distribution Unit \(J58890CH-1\): Front](#) and [Figure 10: Power-Distribution Unit \(J58890CH-1\)](#).

Figure 9: AC Power-Distribution Unit (J58890CH-1): Front

Figure 10: Power-Distribution Unit (J58890CH-1)

Power Backup

The small battery is at the center rear of the multicarrier cabinet. This 8-AH (Amp Hour) battery is fused for short circuit protection and is charged by the J58890CH-1. The batteries also contain a thermal sensor that changes the charging voltage depending on battery temperature.

The small batteries provide short-term battery holdover. If AC power fails, 48-V DC batteries power the system for:

- 1 15 seconds in a PN cabinet
- 1 10 minutes in the expansion control carrier in the "A" position of a PN cabinet

[Figure 11: Small Battery Assembly](#) shows the small battery assembly.

Figure 11: Small Battery Assembly

DC-Powered Cabinets

DC Power-Distribution Unit (J58890CF-2)

[Figure 12: DC Power-Distribution Unit \(J58890CF-2\): Front](#) shows a power-distribution unit in some DC-powered multicarrier cabinets. The unit sits at the bottom of the cabinet and contains the ring generator, 20-Amp circuit breakers, terminal blocks, and system fan power.

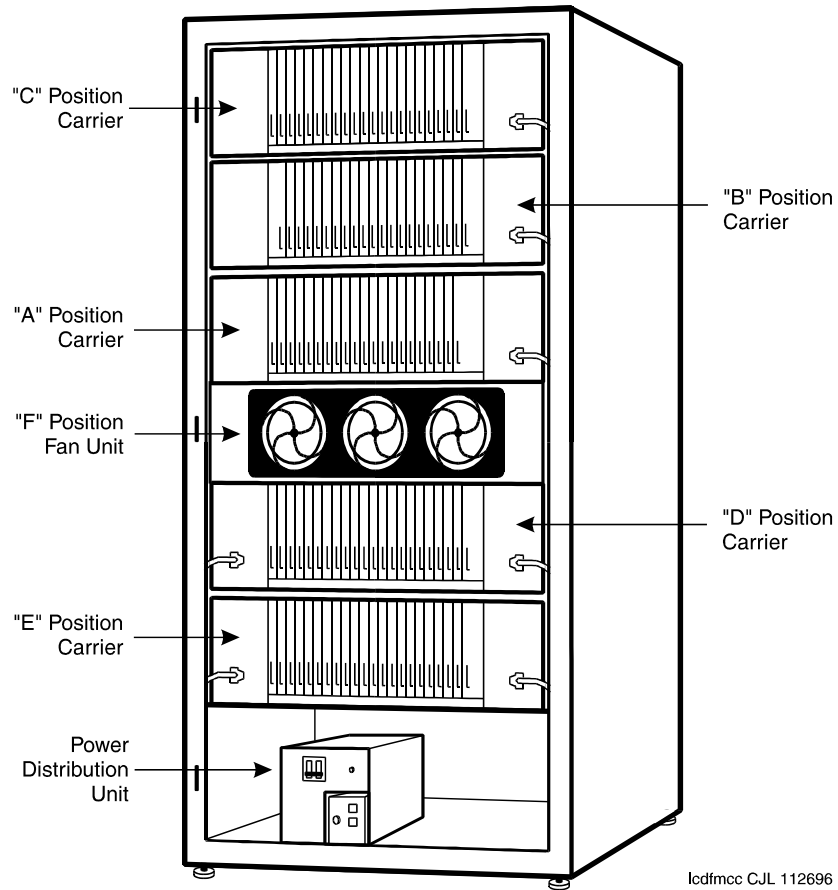

Figure 12: DC Power-Distribution Unit (J58890CF-2): Front

Some carriers may contain two power supplies, the 644A and the 645B, that together supply the required voltages to the carrier. Other carriers may contain one 649A power supply located on the right side of the carrier. In these systems, an additional 649A is located on the right of the optional switch node carriers.

[Figure 13: Typical Multicarrier Cabinet with 649A Power Units](#) shows a typical AC-powered multicarrier cabinet.

Figure 13: Typical Multicarrier Cabinet with 649A Power Units

The table below shows what carriers are protected by each circuit breaker on the J58890CF-1. The ring generator is protected by a fuse located next to the main circuit breaker on the front of the unit.

Circuit Breaker	Associated Carriers
CB1	Carrier A, both sides
CB2	Carrier B, both sides
CB3	Carrier C, both sides
CB4	Carrier D, both sides
CB5	Carrier E, both sides
CB6	Level F (Fans) and Level G (Ring Generator)

The table below shows what carriers are protected by each circuit breaker on the J58890CH-1. The ring generator is protected by a fuse located next to the main circuit breaker on the front of the unit.

Circuit Breaker	Associated Carriers
CB1	Carrier A, both sides
CB2	Carrier B, both sides
CB3	Carrier C, both sides
CB4	Carrier D, both sides
CB5	Carrier E, both sides
CB6	Level F (Fans) and Level G (Ring Generator)

Neon Lamp Power

The system can also support neon message waiting lamps on analog telephones. Any carrier containing a TN769 Neon Analog Line circuit packs must also be supplied with 150 Volts from a TN755B power supply circuit pack. See the table above for other supported neon power circuit packs.

Error log entries and recommended actions

Table 71: CARR-POW Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Recommended Action
1 ¹	0 or 1	OLS Query Test (#127)	MAJ	ON	test environment UU r 2 recycle carrier UUC

1. Run the OLS Query test (#127) using **test environment UU r 2**. If a carrier must be recycled to clear the CARR-POW alarm, use **recycle carrier UUC** to run the OLS Recycle Test (#126). The OLS Recycle test (#126) is not included in either the long or short test sequences.

The OLS Recycle Test (#126) is destructive. For more information, see [OLS Recycle Test \(#126\)](#).

Demand test descriptions and error codes

CDR-LNK (Call Detail Recording Link)

MO Name in Log	Alarm Level	Initial Command to Run	Full Name of MO
CDR-LINK	MIN	<code>test cdr [primary secondary] 1</code>	CDR Link
	WRN	<code>test cdr [primary secondary]</code>	

Refer to [PRI-CDR \(Call Detail Recording Link\)](#) for Call Detail Recording Link problems.

CLAN-BD (Control LAN Circuit Pack)

MO Name in Log	Alarm Level	Initial Command to Run	Full Name of MO
CLAN-BD	MIN	<code>test board location long</code>	Control LAN circuit pack
	WRN	<code>test board location</code>	

Control LAN circuit pack

The TN799 Control LAN (C-LAN) circuit pack provides TCP/IP connection to adjunct applications such as CMS, INTUITY, and DCS Networking. The C-LAN circuit pack has one 100BASE-T Ethernet connection and up to 16 DS0 physical interfaces for PPP connections. C-LAN also extends ISDN capabilities to csi models by providing packet bus access. The TN799DP also supports QoS.

A RSCL (remote socket control link) links the C-LAN and the server to pass call control and other management information. Because one link serves every port on the circuit pack, maintenance of the RSCL is part of the C-LAN circuit-pack maintenance.

C-LAN socket load balancing

The C-LAN socket load balancing feature provides for a more uniform balancing of the load across the available C-LANs. With this feature, an IP endpoint registers to the C-LAN with **the least number of used sockets** (regardless of the number of available sockets). This applies to the following IP endpoints:

- 1 H.245, H.248, and H.323 signaling groups
- 1 H.323 stations
- 1 SIP endpoints

Socket counts include H.245 and H.248 endpoints but the load-balancing algorithm will not be used for registering these endpoints. Sockets used by adjuncts are not included in the socket count.

Note:

This allocation is performed for the C-LANs assigned within each network region, independently of the C-LANs assigned to other network regions.

The system logs a warning to the error log when a TN799x circuit pack has reached the socket usage value specified in the **Number of CLAN Sockets Before Warning** field on the **ip-interfaces** form. The warning can be viewed using `display errors`.

Note:

IP endpoints can still register to this circuit pack after the warning has been issued.

The presence of the warning in the error log indicates that the customer needs to look at the network configuration. The `status socket-usage` command displays socket usage for C-LAN circuit packs in a system. This allows the customer to verify that IP endpoint registration has been evenly distributed, or to determine whether additional TN799x circuit packs are needed.

Also, even though all C-LANs may be available, all endpoints are configured to be in a few specific network regions, and may possibly be overloading the C-LANs in those network regions. This would indicate that additional capacity is required in the affected network regions, or that network configuration and administration needs to be altered to make it more balanced. Additional C-LANs can be administered, or existing administration of C-LANs can be changed using the `add/change ip-interfaces` commands (see *Maintenance Commands for Avaya Aura™ Communication Manager, Media Gateways and Servers (03-300431)* for details).

Note:

When a TN799x is replaced or added, re-balancing does not occur. That is, the system does not un-register an IP endpoint for the purpose of load balancing. Replaced or added TN799x circuit packs will be detected as the least-used C-LANs, and IP endpoints will register with them until the socket load is evenly balanced.

C-LAN congestion controls

The switch activates congestion controls on a C-LAN when it detects a buffer exceeding the threshold. The switch releases the congestion controls when the C-LAN reports that its buffers have returned to normal levels.

If congestion:	Then the switch:
Persists for a 14-minute interval,	Raises MINOR alarm.
Exhausts buffers,	Raises MINOR alarm.
Ceases for 12 minutes,	Retires MINOR alarm.

Notes:

- a. **Error Type 1:** Circuit pack stopped functioning or is not physically present.
1. Verify that the circuit pack is present in the slot indicated by the error. If circuit pack is present, reset the circuit pack with **reset board location**.
 2. If the error persists, replace the circuit pack.
- b. **Error Type 18:** The C-LAN circuit pack is busied out by command.

- c. **Error Type 217:** applies to 10 circuit packs:
 1. Remove the circuit pack(s) against which the error is logged.
- d. **Error Type 257:** Transient communication problems between the switch and circuit pack. This error is not service affecting and can be ignored unless repeated failure of the Control Channel Looparound test (#52) indicates a hardware failure of the circuit pack. If this is the case, replace the circuit pack.
- e. **Error Type 513:** Circuit pack detected a hardware failure. Reset the circuit pack with **reset board location**.
 - Aux Data 4352: External RAM error
 - Aux Data 4353: Internal RAM error
 - Aux Data 4355: ROM Checksum error
 - Aux Data 4357: Instruction set error
- f. **Error Type 769:** Program logic error. By itself this error may be ignored, but it may result in other Error Types being reported.
- g. **Error Type 1290-1297:** A critical hardware or firmware error has been detected on the circuit pack.

If the switch detects:	Then the switch:
1 error,	Resets circuit pack.
3 errors in 15 minutes,	Raises MINOR alarm.

1. Attempt to clear the alarm with **reset board location** command
 2. If the alarm persists, replace circuit pack.
- h. **Error Type 1537:** The circuit pack is hyperactive. The switch has taken it out of service.
 1. Attempt to clear the alarm with the **reset board location** command
 2. If the error happens again within 15 minutes, replace the circuit pack.
 - i. **Error Type 1794:** packet bus transmit buffers have overflowed.
 1. Attempt to clear the alarm with the **reset board location** command.
 2. If the error recurs within 15 minutes, replace the circuit pack.
 - j. **Error Type 1796, Aux Data 42611:** DLCI out of range. The switch activates congestion controls on C-LAN when it detects buffers exceeding the threshold. The switch releases the congestion controls when the C-LAN reports that its buffer level has returned to normal. A minor alarm is raised if congestion persists for 14 minutes or if buffers are exhausted because of congestion. The alarm is retired when the alarm condition ceases for 12 minutes.
 1. Attempt to clear the alarm with **reset board location**.
 2. If the alarm recurs within 15 minutes, replace the circuit pack.

Aux Data Any: Bad DLCI.

- 3. Reset circuit pack with the `busyout board location`, `reset board location`, and `release board location` commands.
- 4. Clear alarms using the `test board long clear` command.
- 5. If the error returns within 15 minutes, replace the circuit pack.

k. **Error Type 1797:** Invalid layer 2 frame received.

l. **Error Type 1798:** Unable to write translation RAM.

- 1. Attempt to clear alarm with `reset board location`.
- 2. If the alarm recurs within 15 minutes, replace the circuit pack.

m. **Error Type 2049:** Packet Interface test (#598) failed.

- 1. Attempt to clear the alarm (`test board location l r 3`).
- 2. If alarm does not clear, reset the circuit pack with `reset board location`.
- 3. If circuit pack resets successfully, execute the Packet Interface test (#598) several times.
- 4. If the Packet Interface test (#598) continues to fail, replace the circuit pack.

n. **Error Type 2305-2306:** Error in a received frame from the packet bus.

Error Type	Description
2305	Received invalid LAPD frame.
2306	Detected parity error on received frame.

- 1. Enter `test board location` and see if the condition clears.
- 2. If the condition persists, execute the Packet Interface test (#598) to verify circuit pack integrity.
- 3. If the Packet Interface test (#598) fails, see [Packet Interface Test \(#598\)](#).

o. **Error Type 2561-2668:** System software received an indication that the socket was closed due to an error. Errors are reported as log only. Errors logged here are for the sockets that had *no* processor channels associated with them, for example, sockets to read SNMP data. The counter base is offset by the application type of the application associated with this socket that is down. The Aux Data field of the log entry contains this application's number, for example, a SNMP application would have its application number in the Aux Data field.

Note:

2561 - 2668 is a range of reserved numbers for future applications.
2570 represents an SNMP socket failure.

- p. **Error Type 2817-2819:** Congestion Query test (#600) failed.
- Error Type 2817: All buffers exhausted.
- Error Type 2819: Utilized buffers exceed threshold
1. Refer to the [Congestion Query Test \(#600\)](#) for repair procedures.
- q. **Error Type 3073:** RSCL (Remote Socket Control Link) failure or [Link Status Test \(#601\)](#) failed. This failure may be due to:
1. Circuit pack problems
 1. Packet bus problems
 1. Packet Interface circuit pack problems
- r. **Error Type 3330:** Critical failure in packet bus interface. If the switch detects 1 error, the circuit pack is reset. If two errors occur within 15 minutes, the switch raises an MINOR alarm.
1. Attempt to clear the alarm with `reset board location`.
 2. If the alarm persists, replace circuit pack.
- s. **Error Type 3586 and 3999:** Switch removed hyperactive circuit pack that reported threshold number of errors. One or more of the following symptoms may be present:
1. Circuit pack port tests return `NO BOARD`.
 1. List configuration command shows circuit pack and ports are installed properly

If Error Type 3999:	And traffic volume is:	Then:
Does not accompany Error Type 3586,	Heavy	Circuit pack is in service, but sent at least half hyperactive threshold. With heavy traffic, this is normal.
Does not accompany Error Type 3586,	Light	Circuit pack is in service, but sent at least half hyperactive threshold. With light traffic, this error indicates a problem with the circuit pack, its links, or the equipment attached to the links.
Accompanies Error Type 3586,	Light or Heavy	Switch removed hyperactive circuit pack.

1. Busyout (`busyout board location`) and release (`release board location`) circuit pack
2. Allow 30 minutes for condition to clear itself.
3. To re-establish circuit pack into service manually, busyout (`busyout board location`), reset with `reset board location`, and release (`release board location`) the circuit pack.
4. If error recurs within 15 minutes, replace the circuit pack.

5. If the same error occurs on a different circuit pack, follow normal escalation procedures.
- t. **Error Type 3840:** Circuit pack received bad control channel message from switch.
- Aux Data:
- 4096 - Bad major heading
 - 4097 - Bad port number
 - 4098 - Bad data
 - 4099 - Bad sub-qualifiers
 - 4100 - State inconsistency
 - 4101 - Bad logical link
 - 4102 - Bad application identifier
- u. **Error Type 3841-3843:** errors do not affect service.
- Error Type 3841:** Internal firmware error
- Error Type 3841:** Bad translation RAM. Call uses another translation location.
- These errors do not affect service. However, they may cause other errors that do affect service.
- If Error Type 3843 begins to affect service, it escalates to Error Type 1294.
- v. **Error Type 3842:** Packet interface receive buffers overflowed.
- If this error occurs frequently, the overflow may be congesting the circuit pack.
1. Refer to [Receive FIFO Overflow Error Counter Test \(#596\)](#).
- w. **Error Type 3844:** LAPD frame contains LAPD protocol error.
- By themselves, these errors do not affect service.
- x. **Error Type 3845:** Angel interprocessor error.
- By themselves, these errors do not affect service.
- y. **Error Type 3846:** High CPU occupancy.
- By themselves, these errors do not affect service.
- z. **Error Type 3848:** Interprocessor LAPD protocol error.
- By themselves, these errors do not affect service.
- aa. **Error Type 3849:** Interprocessor LAPD frame error.
- By themselves, these errors do not affect service.
- ab. **Error Type 3850 - 3861:** IBL error.
- By themselves, these errors do not affect service. These errors can occur only on a G3csi machine that has an Interboard Link (IBL).
- ac. **Error Type 3862:** Memory allocation failure.
- By themselves, these errors do not affect service.

- ad. **Error Type 3865:** [S8700 Series](#) | [S8500](#): C-LAN DLCI audit action has removed CIP only DLCIs. By themselves, these errors do not affect service.
- ae. **Error Type 3866:** [S8700 Series](#) | [S8500](#): C-LAN DLCI audit action has removed C-LAN only DLCIs. By themselves, these errors do not affect service.
- af. **Error Type 2820:** A threshold number of sockets in use for IP endpoint registration per C-LAN can be administered by the customer. When the threshold is reached, a warning message is logged, but IP endpoints can still register with that C-LAN if it has additional sockets available. The warning can be viewed using **display errors**.

Demand test descriptions and error codes

Investigate tests in the order presented. By clearing errors associated with the first test, errors generated from other tests may also be cleared. Click on the link to see the full description of the test, error codes, and recommended actions.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND ¹
Control Channel Looparound Test (#52)	X	X	ND
Circuit Pack Restart Test (#252)			D

CLSFY-BD (Call Classifier Circuit Pack)

MO Name in Log	Alarm Level	Initial Command to Run	Full Name of MO
CLSFY-BD	MIN WRN	<code>test board location</code>	Call Classifier circuit pack

See [XXX-BD \(Common Port Circuit Pack/Media Module\)](#) for circuit pack-level errors.

See [CLSFY-PT \(Call Classifier Port\)](#) for related port information.

CLSFY-PT (Call Classifier Port)

MO Name in Log	Alarm Level	Initial Command to Run	Full Name of MO
CLSFY-PT	MAJ MIN WRN	<code>test port location</code>	Call Classifier Port

The TN744 Call Classifier is a service circuit pack that provides specialized tone detection capabilities to support the Outbound Call Management (OCM) and Inbound Call Management (ICM) features. The TN744 supports both A-law and Mu-law companding.

The TN744 has eight ports (CLSFY-PTs), each capable of supporting call classification, touch-tone reception and MFC-tone generation and detection. The CLSFY-PT MO implements a set of tests designed to ensure proper operation of the Call Classifier.

Error log entries and recommended actions

Table 73: CLSFY-PT Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Recommended Action
1	any	Tone Detector Audit/Update Test (#43)	MAJ / MIN (a)	ON	<code>test port location r 2</code>
18		<code>busyout port</code>	WRN	OFF	<code>release port location</code>
257 (b)	17666	Tone Detector Audit/Update Test (#43)	MAJ / MIN (a)	ON	<code>test port location r 3</code>
513 (c)	any	Tone Detection Verification Test (#42)	MAJ / MIN (a)	ON	<code>test port location r 3</code>

Notes:

- a. A major alarm is raised if the total number of call classifier ports currently in-service is less than or equal to 1/2 of the administered threshold number. For major or minor alarm, run the short test sequence on the alarmed port and follow the error code procedures for the individual tests.

The in-service threshold number for alarming call classifier ports is administered using the `change system-parameters maintenance`.

1. Enter these commands in order: **busyout board**, **reset board**, **release board**. The board reset is required to reload on-board RAM associated with the TN744's DSPs. This takes all 8 Tone Detector ports out of service for a few seconds. Only 4 of the 8 would be out of service due to the alarm. (There are five Tone Detectors on each of the two DSPs.) Other than the unlikely potential of running out of Tone Detector resources in the switch, there is no other effect when the board is reset.
 2. Test the board with **test board location long**.
 3. If the test still fails, replace the board.
- b. **Error 257:** The CLSFY-PT lost its translation. Testing the CLSFY-PT is sufficient to reload its translation. If testing the call classifier port does not clear the error, then the call classifier circuit pack containing the defective call classifier port should be replaced.
- c. **Error 513:** This error indicates the call classifier port is having problems detecting call classification tones or detecting and generating R2-MFC tones This is usually accompanied by failures of some incoming or outgoing calls. If this Error Type is persistently logged, then replace the call classifier circuit pack containing the defective CLSFY-PT.

CO-BD (Central Office Trunk Circuit Pack)

MO Name in Log	Alarm Level	Initial Command to Run	Full Name of MO
CO-BD	MIN WRN	<i>test board location</i>	Central Office Trunk circuit pack

See [XXX-BD \(Common Port Circuit Pack/Media Module\)](#) for circuit pack-level errors.

See [CO-TRK \(Analog CO Trunk\)](#) for related trunk information.

CO-DS1 (DS1 CO Trunk)

MO Name in Log	Alarm Level	Initial Command to Run	Full Name of MO
CO-DS1	MAJ ¹ MIN	<code>test trunk grp#/mem# 1</code>	DS1 CO Trunk
	WRN	<code>test trunk grp#/mem#</code>	

1. A Major alarm on a trunk indicates that alarms on these trunks are not downgraded by `set options` and that at least 75 percent of the trunks in this trunk group are alarmed. For more information about `set options`, see *Maintenance Commands for Avaya Aura™ Communication Manager, Media Gateways and Servers (03-300431)*.

Note:

For media gateways, consult local records for the location and designation of the equipment rack where the media gateway is mounted.

Many trunk problems are caused by incorrect settings of parameters on the trunk group administration screen. Settings must be compatible with the local environment and with parameter settings on the far end. Refer to the *Administering Avaya Aura™ Communication Manager* for information on how to administer trunks. Refer to your Avaya representative for the correct settings for administrable timers and other parameters on a country-by-country basis.

A DS1 CO (central office) trunk provides a link for digitized voice or data communications between the system and a central office switch. There are two types of DS1 interfaces:

- 1 24 DS0 channels on a 1.544-Mbps link
- 1 31 DS0 channels + 1 framing channel on a 2.048-Mbps link

32-channel mode is supported on the TN464C or higher suffix, TN2207, and TN2464 circuit packs, and on DS1 Interface Media Modules.

The DS1-CO MO monitors and maintains a CO trunk port on a TN767 DS1 Interface circuit pack, a TN464 UDS1 Interface circuit pack, or on DS1 Media Modules. Throughout this discussion, the term DS1 applies to all. For more information, see one of the following maintenance objects:

Circuit Pack/Media Module	Maintenance Object
TN767 DS1 Interface Circuit Pack	DS1-BD
TN464 UDS1 Interface Circuit Pack	UDS1-BD
DS1 Interface Media Modules	MG-DS1

The DS1 circuit pack or media module supports low level CO trunk signaling interfaces for both ground-start and loop-start trunks.

The DS1 Interface Media Module supports T1/E1, and delivers the same functionality as the TN464 circuit pack.

Three trunk service states are specified by DS1 CO trunk maintenance:

out-of-service	The trunk is in a deactivated state and cot be used for either incoming or outgoing calls.
in-service	The trunk is in an activated state and can be used for both incoming and outgoing calls.
disconnect (ready-for-service)	The trunk is in an activated state but can only be used for an incoming call.

Error log entries and recommended actions

Table 74: CO-DS1 Error Log Entries 1 of 2

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Recommended Action

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Recommended Action
3840 (I)		Port Audit and Update (#36)			
					2 of 2

1. CO-DS1 Major alarms may be downgraded to Warning alarms based on the value used in **set options**.

Notes:

- Error Type 0:** Run the short test sequence first. If every test passes, run the long test sequence. Refer to each appropriate test's description, and follow its recommended procedures.
- Error Type 1:**

Aux Data 57408: No tip ground is detected on an outgoing call.

Aux Data 57487: PBX could not get "loop close" signal.

If the error occurred on a port of a TN767 DS1 or TN464 UDS1 Interface circuit pack, the circuit pack detected a hardware fault. These errors will cause the DS1 Dial Tone Test #314 to run and are only considered a problem if the Dial Tone test fails (in which case Error Type 1025 will also show up). In this case, the trunk may be put in the ready-for-service state (shown as "disconnected" by **status**), which allows only incoming calls. Run the DS1 Dial Tone Test #314, and follow the procedures.
- Error Type 15:** software audit error that does not indicate any hardware malfunction. Run the short test sequence, and investigate associated errors (if any).
- Error Type 18:** the trunk was busied-out and is in an out-of-service state. No calls can be made on this trunk except Facility Access Test Calls. Release the trunk and retest.
- Error Type 130:** the circuit pack has been removed or has been insane for more than 11 minutes. To clear the error, reinsert or replace the circuit pack or media module.
- Error Type 257:** the DS1 Interface circuit pack detects a hardware fault. Aux Data 57392 indicates no external release on PBX disconnect. This alarm will only be raised when the System-Parameter Country screen has the Base Tone Generator field set to 4 (Italy). This alarm will be a MINOR alarm unless 75% or more trunks in this trunk group are out of service, then the alarm will be upgraded to a MAJOR alarm.
- Error Type 513:** The DS1 Interface circuit pack detects a hardware fault. Aux Data 57393 indicates belated external release on PBX disconnect. This alarm will only be raised when the System-Parameter Country screen has the Base Tone Generator field set to 4 (Italy). This alarm will be a MINOR alarm unless 75% or more trunks in this trunk group are out of service, then the alarm will be upgraded to a MAJOR alarm.
- Error Type 769:** The DS1 Interface circuit pack or media module detects a hardware fault. The Aux Data contains the following Error Type:—57484, fault is detected on tip/ring.

- i. **Error Type 1793:** DS1 Interface circuit pack or media module is out-of-service. Look in the Error Log:

If the port is on	Look at
TN767 DS1 Board	DS1-BD (DS1 Interface Circuit Pack)
TN464 UDS1 Board	UDS1-BD (UDS1 Interface Circuit Pack)
DS1 Interface Media Module	MG-DS1 (DS1 Interface Media Module)

- j. **Error Type 2562:** Retry Failure error. This error is logged only. It is not a hardware failure and hence does not start any testing or generate any alarms. This error comes from call processing and is generated when a second attempt (retry) to seize an outgoing trunk fails.
- k. **Error Type 2817:** Glare error. This error is logged only. It is not a hardware failure and hence does not start any testing or generate any alarms. This error is the result of a simultaneous seizure of a 2-way trunk from both the near and far ends. Attempt to place the call again. If the error persists, execute the Dial Tone Seizure test (#314), and follow those procedures.
- l. **Error Type 3840:** Port Audit and Update test (#36) failed due to an internal system error. Enter `status trunk` to verify the status of the trunk. If the trunk is out-of-service, then enter `release trunk` to put it back into in-service. Retry the test command.

Demand test descriptions and error codes

Investigate tests in the order presented. By clearing errors associated with the first test, errors generated from other tests may also be cleared. Click on the link to see the full description of the test, error codes, and recommended actions.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND ¹
NPE Crosstalk Test (#6)		X	ND
Conference Circuit Test (#7)		X	ND
DS1 CO Trunk Dial Tone Seizure Test (#314)	X	X	ND
Port Audit And Update Test (#36)	X	X	ND

1. D = Destructive; ND = Nondestructive

CO-TRK (Analog CO Trunk)

MO Name in Log	Alarm Level	Initial Command to Run	Full Name of MO
CO-TRK	MAJ ¹ MIN WRN	<code>test port location</code>	Analog CO Trunk

1. A MAJOR alarm on a trunk indicates that alarms on these trunks are not downgraded by **set options** and that at least 75% of the trunks in this trunk group are alarmed.

For systems supporting circuit packs:

If ATMS testing is enabled, check the error log for ATMS errors 3840 and 3841. If the error log indicates that measurements exceeded acceptable thresholds, and no other trouble is found with `test trunk`, run the ATMS test call with `test analog-testcall port location full`.

Note:

Many trunk problems are caused by incorrect settings of parameters on the trunk group administration screen. Settings must be compatible with the local environment and with parameter settings on the far end.

Analog CO trunks are 2-wire analog lines to the CO that support both incoming and outgoing calls. CO trunk circuit packs have eight ports, each of which provides an interface between the 2-wire CO line and the 4-wire TDM bus. The system supports the following CO trunk circuit packs:

TN438	TN2138
TN447	TN2147
TN465	TN2148
TN747	

For systems supporting media modules:

Analog CO trunks are 2-wire analog lines to the CO which support both incoming and outgoing calls. CO trunk MM711 Analog Media Modules have eight ports.

Not all tests in the demand test sequences are applicable for media modules. These tests will abort with error code 1412. This error can be ignored.

The following sequences show the interactions between the switch and the CO during call setup for both loop-start and ground-start trunks.

Interactions between switch and CO

The following sequences show the interactions between the switch and the CO during call setup for both loop-start and ground-start trunks.

Loop Start Operation

Idle State:

Tip = ground, Ring = CO Battery

Outgoing Call:

PBX Off-Hook (Seize message): Closes the Tip-Ring Loop

CO response: DC loop current + Dial tone

PBX On-Hook (Drop message): Open Tip-Ring loop, no loop current

CO response: CO goes to idle state (see Note)

Incoming Call:

CO Applies Ringing Voltage

PBX response: Detect ringing current

PBX Off-Hook (Answer message): Close loop

CO response: Trip ringing, provide loop current

PBX On-Hook (Drop message): Open Tip-Ring loop, no loop current

CO response: CO goes to idle state

Note:

CO does not normally provide an On-Hook (Disconnect) signal. Exceptions to this rule include Netherlands loop start and UK loop-calling guarded-clearing.

Ground Start Operation

Idle state:

Tip = open, Ring = CO Battery

Outgoing Call:

PBX Off-Hook (Seize message): Places ground on Ring

CO response: Places ground on Tip

PBX response: Close the loop

CO response: Provide loop current

PBX response: Dial out digits

PBX On-Hook first (Drop message): Open the Tip-Ring Loop, no loop current

CO response: Open circuit on Tip

CO On-Hook first (Disconnect): Open circuit on Tip, no loop current

PBX response: Open Tip-Ring loop

Incoming Call:

CO Off-Hook (Seizure): CO applies ground on Tip and applies ringing voltage to the Ring lead.

PBX response: Make trunk busy for outgoing calls

CO Ringing: CO applies ringing voltage to the Ring lead.

PBX response: Detect ringing, ring destination (Attendant, hunt group, etc.)

PBX Off-Hook (Answer message): Close loop

CO response: Trip ringing, provide loop current

PBX On-Hook first (Drop message): Open the Tip-Ring Loop, no loop current

CO response: Open circuit on Tip

CO On-Hook first (Disconnect): Open circuit on Tip, no loop current

					2 of 2

1. Major alarms may be downgraded to Warning alarms based on the value used in **set options**.

Notes:

- a. **Error Type 0:** Run the short test sequence first. If every test passes, run the long test sequence. Refer to each appropriate test's description, and follow its recommended procedures.
- b. These are inline errors that have no specific test associated with them. Numerous Error Types have these errors. Refer to [Table 76: CO Trunk Errors with No Tests](#) for an explanation and appropriate action.
- c. **Error Type 15:** software audit error that does not indicate any hardware malfunction. Run short test sequence, and investigate associated errors.
- d. **Error Type 130:** the circuit pack has been removed or has been insane for at least 11 minutes. To clear the error, reinsert or replace the circuit pack.
- e. Numerous Error Types have these errors.

Aux data 57345: Single polarity ringing current

Aux data 57376: No loop current on incoming call

Aux data 57408: No tip ground detected on outgoing call

Aux data 57424: No loop current on outgoing call

Aux data 57484: No dial tone on outgoing call

These errors will cause Dial Tone Test #0 to run and are only considered a problem if the Dial Tone test fails (in which case Error Type 1537 will also show up). In this case, the trunk may be put in "Ready-for-Service" state (shown as "disconnected" by status command), that allows only incoming calls. Run Dial Tone Test #0, and follow its outlined procedures.

If error count associated with this Error Type is very high (i.e., 255) and if Alarm Status on the Hardware Error Report is “n” (not alarmed), then the existence of this Error Type indicates that, despite the fact that many inline error messages have been received, every Call Seizure test has passed. Problems at the CO may cause this condition rather than problems with the PBX.

- f. **Error Types 1025/1281:** logged for every version of the CO-TRK/CO-BD. However, no MINOR alarms will be generated for Central Office Trunks [TN747B] with vintages V8 or greater. Any failures received by this test will still be logged as Error type 1025/1281.

Check for the use of MFT/Range extenders. If there are extenders present, and there are no other complaints or maintenance errors against this trunk, then there is a good chance that Test #3 failed due to excessive loop current and may be ignored.

- g. **Error Type 3840:** test calls made by the Automatic Transmission Measurement System (ATMS) returned measurements in the unacceptable range.

Error Type 3841: measurements were in the marginal range. Enter `list testcall detail` to examine the specific transmission parameters that are out of spec, and investigate the trunk for that kind of noise. If the noise is acceptable, then the AMTS thresholds administered on the trunk group screen should be changed.

Table 76: CO Trunk Errors with No Tests 1 of 3

Error Type	Aux Data	Error Description and Repair Action
1	57347	Port error. Ringing without ground. This error is detected on an incoming call on a ground-start CO trunk. The CO trunk circuit pack has not detected a Tip ground before ringing current is detected. This may indicate that the ground detector is not working. However, the call will be accepted. Busyout the affected port, and run a long test. Observe the test results. If any tests fail, refer to the description of the tests and the associated error codes. Release the port. If users continue to report troubles, check for other errors and make test calls to determine whether the problem should be referred to the CO.
257	50176	Battery reversal detected. This is usually caused by the CO. This is detected if the direction of the loop current changes from normal to reverse for at least 40 msec. Could occur if the trunk was just installed and for some reason the Tip and Ring wires were reversed at the PBX. If battery reversals occur during dialing, wrong numbers may result. Refer problem to CO. Ask them to remove the battery reversal option.
513	57364	Ground detector stuck active. After several occurrences, an on-board minor alarm is generated. Run the short test sequence. If test aborts with Error Code 1000, disconnect Tip and Ring and repeat short test. If test still aborts, replace circuit pack. If test passes, refer problem to CO. If any other error code is received, pursue that problem.
1 of 3		

Table 76: CO Trunk Errors with No Tests 2 of 3

Error Type	Aux Data	Error Description and Repair Action
769	57392	CO not releasing after call is dropped from PBX end, or the loop is not open after a disconnect. After several occurrences, an off-board or on-board warning alarm is generated. Refer problem to CO.
2561	57345	Single polarity ringing current. This error results from abnormal ringing current, but does not prevent the incoming call from being accepted. One cause could be that the reverse current detector associated with the port is failing. (Will not be detected by any tests.) Another cause could be that normal current is not detected. In this case, neither incoming nor outgoing calls can be completed, and the dial tone test will also fail. The last cause could be that certain types of noise are present on the CO line during the silent period of ringing. First check for other errors. If the count for this error is very high (255), and every test passes, then either the reverse current detector is defective or the CO line is noisy. If the CO line is suspect, make Tip and Ring observations. If the line is determined to be noisy, refer the problem to the CO. If the reverse current detector is defective, ignore this error.
2817	57360	Ground but no ringing. This error occurs on an incoming call on a ground-start trunk. If ringing is not detected within 5 seconds of the Tip being grounded, the call is still accepted. If the CO is of the No. 5ESS. switch type, ringing delays of more than 5 seconds during heavy traffic are fairly common. Check for other errors.
2817	57393	The loop is opening too slowly after a disconnect. This error indicates an on-board problem, although the trunk may be functional. Check for other errors.
3073	57376	No loop current on incoming call. The incoming destination has already answered and no loop current has been detected. If this is a hard fault, the dial tone test and every outgoing call should also fail. Check for other errors.
3329	57408	<p>Trunk error. No Tip ground detected on outgoing call. This error occurs when an attempt is made to seize a ground-start CO trunk for an outgoing call and Tip ground is not detected or the caller hangs up before Tip ground is detected.</p> <ol style="list-style-type: none"> 1. Busyout the affected port, and run a long test. Observe the test results. If any tests fail, refer to the description of the tests and the associated error codes. Release the port. 2. If users continue to report troubles, check for other errors and make test calls to determine whether the problem should be referred to the CO. Busyout the affected port, and run a long test. If Dial Tone Test #0 passes, ignore this error. Release the port.
2 of 3		

Table 76: CO Trunk Errors with No Tests 3 of 3

Error Type	Aux Data	Error Description and Repair Action
3585	57424	No loop current on outgoing call. This error occurs on attempt to seize a loop or ground-start trunk for an outgoing call. An error occurs if loop current is not detected or the caller hangs up before it is detected. Busyout the affected port, and run a long test. If the CO Port Diagnostic Test #3 passes and this error keeps occurring, refer problems to CO. Release the port.

Demand test descriptions and error codes

Investigate tests in the order presented. By clearing errors associated with the first test, errors generated from other tests may also be cleared. Click on the link to see the full description of the test, error codes, and recommended actions.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND ¹
NPE Crosstalk Test (#6)		X	ND
Dial Tone Test (#0)		X	ND
CO Port Diagnostic Test (#3)	X	X	ND
Looparound and Conference Test (#33)		X	ND
Port Audit And Update Test (#36)	X	X	ND
Automatic Transmission Test (#844-848)			ND

1. D = Destructive; ND = Nondestructive

Note:

The CO Port Diagnostic Test (#3) will always return a PASS indication for CO-TRK/CO-BD [TN747B] version 8 or greater. However, any errors produced as a result of this test will be logged and produce no alarms.

If errors logged by Test #3 are the only complaints against this trunk, then check if MFT/Range Extenders are being used. If extenders are present, then there is a good chance that there is excessive loop current, which will cause Test #3 to log errors.

However, all else being normal, these errors should not affect the customer.

Note:

The ATMS tests are not part of either test sequence. They are run either on demand with `test analog-testcall` or by the ATMS schedule.

CONFIG (System Configuration)

MO Name in Log	Alarm Level	Initial Command to Run	Full Name of MO
CONFIG	none	none	System Configuration

The System Configuration MO oversees logical insertion and removal of circuit packs in the system. When the system detects that a circuit pack is present in a port slot, it queries the circuit pack to determine the type and vintage of the circuit pack. The system also detects when a circuit pack has been removed from a port slot.

There are no alarms or tests for System Configuration, but three types of errors are logged to the error log.

Error log entries and recommended actions

Table 77: CONFIG Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Recommended Action
0 (a)	0				
1–119 (b)	0–63				
257 (c)			MAJ		
1001–1119 (d)	0–63				

Notes:

- a. **Error Type 0:** An attempt was made by the system to raise an alarm against CONFIG without first logging a CONFIG error.
- b. **Error Types 1-119:** a port circuit pack in the system did not respond to a circuit pack type inquiry. Follow the procedures outlined in (d) to determine whether there is an error.
- c. **Error Type 257:** less than 25% of a trunk group is available.
- d. **Error Types 1001 - 1119:** a port circuit pack in the system did not respond to a vintage inquiry. A port circuit pack may be physically inserted in a port slot, but the system may not recognize its existence. The `Aux Data` value specifies the circuit pack's internal port network number. To convert the `Aux Data` value to the physical port network number, add

'1' to the `Aux Data` value. For example, if the `Aux Data` value is '0', the port network number is 1. If the `Aux Data` value is '29', the port network number is 30.

The **Error Type** field specifies the carrier and slot location of the circuit pack that caused the error as indicated in [Table 78: Converting Error Types To Carrier Locations](#). If the **Error Type** is greater than 1000, subtract 1000 from the **Error Type** field before consulting the table.

S8700 Fiber-PNC: Before proceeding, if multiple CONFIG errors are simultaneously logged with an `Aux Data` of 1, investigate any [EXP-INTF \(Expansion Interface Circuit Pack\)](#) errors.

Once the port's circuit-pack location has been determined, use `list configuration a11` to determine whether the circuit pack is inserted. If the circuit pack has already been inserted but the error persists, replace the circuit pack. If not, insert the pack.

Notes:

- a. **Error Types 1, 23, 25, 25, 26, 32, 33, 55, 64, 65, 87, 96, 97, 119** do not represent physical port circuit pack slots and are not logged against CONFIG.
- b. If **Error Type 28** occurs in a PN, it refers to the circuit pack in slot A01.
- c. If **Error Type 61** occurs in a PN, it refers to the circuit pack in slot A10.
- d. **Error Type 22, 54, 86, 118**: Slots B00, C00, D00, and E00 refer to the *Service Slots* in the B, C, D, and E carriers.
- e. **Error Type 27**: In a PN's A carrier, slot A00 is the Tone Generator's slot.

CUST-ALM (Customer-Provided Alarming Device)

See [MAINT \(PN Maintenance Circuit Pack\)](#) for information about this maintenance object.

DAT-LINE (Data Line Port)

MO Name in Log	Alarm Level	Initial Command to Run	Full Name of MO
DAT-LINE	MIN WRN	<code>test port location 1</code>	Data Line port

The TN726 Data Line circuit pack has eight ports, each of which supports an RS-232 interface to asynchronous CPE (customer-premises equipment). Each of these ports and the equipment connected to it constitute a data line.

For DT-LN-BD (Data Line circuit pack) errors, see [XXX-BD \(Common Port Circuit Pack/Media Module\)](#). Check circuit pack-level errors first since the usability of the ports depend on the health of the circuit pack.

Enter `add data-module` to administer data line ports at the terminal. The data module type is *data-line*. The `list data-module` command shows every administered data module in the system.

The TN750 announcement circuit pack has one data line-type port on it. This data line port is used for saving and restoring announcements. This data line port is not supported on the S8500 and S8700-series servers. For a description of and repair instructions for the TN750, see [ANL-BD \(Analog Line Circuit Pack\)](#).

Note:

If the tests for the data line port in question pass, and user-reported complaints persist, there is probably an external problem. Test the ADU (asynchronous data unit), using the procedures in *Multiple Asynchronous Data Unit User Manual*, 555-401-702. If the ADU appears to be working properly, check the external wiring, then check the equipment.

Error log entries and recommended actions

Table 79: DAT-LINE Error Log Entries 1 of 2

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Recommended Action

769(d)	40983				
					2 of 2

Notes:

- a. **Error Type 0:** Run the short test sequence first. If every test passes, run the long test sequence. Refer to each test's description, and follow its recommended procedures.
- b. **Error Type 15:** Software audit error that does not indicate any hardware malfunction. Run the short test sequence, and investigate errors.
- c. **Error Type 130:** The circuit pack has been removed or has been insane for more than 11-minutes. To clear the error, reseal or replace the circuit pack.
- d. **Error Type 769:** the data line circuit pack found an error in the transmit/receive circuitry of an administered data line when the circuit pack was inserted. Perform the following:
 1. Enter *busyout board location* for the circuit pack on which the port resides.
 2. Enter *reset board location*. Check the Error Log to determine whether Error Type #769 is logged again for DAT-LINE. Verify that the **Active Alarms Only** field is **n**.
If Error Type #769 reappears, replace the data line circuit pack. If not, enter *release board location*.

DC-POWER (Single-Carrier Cabinet Environment)

S8700 Series

MO Name in Log	Alarm Level	Initial Command to Run	Full Name of MO
DC-POWER	MAJ	test environment location (<i>location</i> is the universal cabinet number in the PORT field of the alarm log)	Single-Carrier Cabinet Environment

Two different cabinet types are supported: multicarrier and single-carrier. Single-carrier cabinets are used only for PNs. Both cabinet types may be powered by either AC or DC external power source. Environmental maintenance differs according to cabinet type and external power supply. Refer to the following table to determine which MO documentation to use for environmental maintenance.

Cabinet Type	Power Source	Environmental Maintenance Objects
Single-carrier (PN)	AC or DC	DC-POWER (all environmental maintenance)
Multicarrier	AC	AC-POWER for AC-powered systems (external power source) POWER for AC-powered systems (battery backup) CARR-POW (carrier port power supply) CABINET (temperature and fan sensors)
Multicarrier	DC	CARR-POW (carrier port power supply) CABINET (temperature and fan sensors)

The DC-POWER MO represents all environmental maintenance for single-carrier cabinets, whether the external power supply is AC or DC. This includes the external power supply and every Carrier Port Power Supply in an PN composed of a single-carrier cabinet stack. A Carrier Port Power Supply provides +5, -5, and/or -48 Volts DC to the circuit packs on the carrier. The following power supplies are used:

WP-91153	Accepts AC power input
676B	Accepts DC power input

Each power unit has one amber LED. A lit LED signifies normal operation. An unlit LED signifies a loss of external power to the cabinet, or a fault in the power unit. When hardware detects a problem with any of these components, it reports the information to the system software through a single lead. System software does not differentiate between different environmental failures. Since several environmental elements of single-carrier cabinets are logged against the DC-POWER MO, it is possible to have a DC-POWER alarm while there is still power to the system.

If a Carrier Port Power Supply is physically removed from a carrier in a single-carrier cabinet, there will not be a DC-POWER alarm. DC-POWER maintenance can distinguish between removal of the power supply and the physical absence of the cabinet.

There is a nominal power holdover of .25 second in an PN single-carrier cabinet.

Error log entries and recommended actions

Table 80: Single-Carrier Cabinet Power Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Recommended Action ¹
0 ²	0	Any	Any	Any	test environment UU
513	0 or 1	Single-carrier cabinet power query test (#79)	MAJ	ON	test environment UU r 2

1. UU is the universal cabinet number indicated in the PORT field of the Alarm Log.

2. Run the short test sequence first. If every test passes, run the long test sequence. Refer to each test's description and recommended procedures.

DETR-BD (Tone Detector Circuit)

MO Name in Log	Alarm Level	Initial Command to Run	Full Name of MO
DETR-BD	MIN WRN	<code>test board location</code>	Tone Detector circuit

For proper tone detection, the companding mode administered for the system must match that of the DETR-BD circuit. The companding mode is administered on the `location-parameters` screen.

See [XXX-BD \(Common Port Circuit Pack/Media Module\)](#) for DETR-BD (Tone Detector circuit) errors.

DID-BD (Direct Inward Dial Trunk Circuit Pack)

MO Name in Log	Alarm Level	Initial Command to Run	Full Name of MO
DID-BD	MIN WRN	<i>test board location</i>	Direct Inward Dial Trunk circuit pack

See [XXX-BD \(Common Port Circuit Pack/Media Module\)](#) for circuit pack-level errors.

See [DID-TRK \(Direct Inward Dial Trunk\)](#) for related trunk information.

DID-DS1 (Direct Inward Dial Trunk)

MO Name in Log	Alarm Level	Initial Command to Run	Full Name of MO
DID-DS1	MAJ ¹ MIN	<code>test trunk grp#/mem# long</code>	Direct Inward Dial Trunk
	WRN	<code>test trunk grp#/mem#</code>	

1. A Major alarm on a trunk indicates that alarms on these trunks are not downgraded by `set options` and that at least 75 percent of the trunks in this trunk group are alarmed.

The DID-DS1 trunk provides a digital Direct Inward Dial (DID) trunk from a CO switch to the system through a DS1 link. A 24-channel DS1 link can support up to 24 DID-DS1 trunk calls simultaneously. A 32-channel link can support up to 30.

A DID-DS1 trunk can be used for digitized voice and data communications with DS1 signaling mode (for example, common-channel signaling). The TN767 and TN464 circuit packs and the DS1 Interface Media Module support wink-start and immediate-start trunks and Communication Manager signaling. Throughout this section, the term DS1 applies to all. For more information, see one of the following maintenance objects:

Circuit Pack/Media Module	Maintenance Object
TN767 DS1 Interface Circuit Pack	DS1-BD
TN464 UDS1 Interface Circuit Pack	UDS1-BD
DS1 Interface Media Module	MG-DS1

Not all tests that run on circuit packs are applicable to media modules. These tests will abort with error code 1412. This error can be ignored.

Two trunk service states are specified in the DID-DS1 trunk maintenance:

- out-of-service The trunk is in a deactivated state and cannot be used for incoming calls.
- in-service The trunk is in an activated state and can be used for incoming calls.

If a DS1 is out-of-service, every trunk on the circuit pack or media module is put into the out-of-service state, and a Warning alarm is raised.

Error log entries and recommended actions

Table 81: DID-DS1 Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Recommended Action
0 (a)	0	Any	Any	Any	<code>test trunk grp#/mem#</code>
1 (b)	Any				
15 (c)	Any	Port Audit and Update test (#36)			
18 (d)			WRN	OFF	<code>release trunk grp#/mem#</code>
130 (e)			WRN	ON	<code>test trunk grp#/mem#</code>
257 (f)	57474 57473				
513 (g)	57392		MAJ MIN ¹		
769 (h)	57393		MAJ MIN ¹		
1281		Conference Circuit Test (#7)	MIN WRN ²	ON	<code>test trunk grp#/mem# long r 4</code>
1537		NPE Crosstalk Test (#6)	MIN WRN ²	ON	<code>test trunk grp#/mem# long r 3</code>
1793 (i)					<code>test board location long</code>
2305 (j)	50944		MAJ MIN ¹	OFF	
3840 (k)		Port Audit and Update (#36)			

1. This alarm is raised only when the Base Tone Generator field is 4 (Italy) on the System-Parameter Country screen. This alarm is a MINOR alarm unless 75% or more trunks in this trunk group are out of service, when the alarm is upgraded to a MAJOR alarm.

2. Major alarms may be downgraded to Warning alarms based on the value used in `set options`.

Notes:

- a. **Error Type 0:** Run the short test sequence first. If every test passes, run the long test sequence. Refer to each test's description, and follow its recommended procedures.

- b. **Error Type 1:** DS1 Interface circuit pack or media module detects a hardware error on the DS1 DID trunk. The `Aux Data` field indicates the following:

57476	On-hook before wink
57477	On-hook before ready to receive digits
57485	Wink too short for valid signal

Maintenance does not start any testing or generate any alarms in response to these errors.

- c. **Error Type 15:** Software audit error that does not indicate hardware malfunction. Run short test sequence, and investigate any errors.
- d. **Error Type 18:** The trunk has been taken out of service by a demand busyout. No calls can be made on this trunk.
- e. **Error Type 130:** the circuit pack or media module has been removed or has been insane for more than 11 minutes. To clear the error, reinsert or replace the circuit pack or media module.
- f. **Error Type 257:** DS1 Interface circuit pack or media module detects a hardware error on the DS1 DID trunk. The `Aux Data` field indicate the source of the error:

57473	Rotary dial rate above 8 pulses per second
57474	Rotary dial rate below 12 pulses per second

- g. **Error Type 513:** DS1 Interface circuit pack or media module detects a hardware error on the DS1 DID trunk. `Aux Data 57392` indicates no external release on PBX disconnect.
- h. **Error Type 769:** DS1 Interface circuit pack or media module detects a hardware error on the DS1 DID trunk. `Aux Data 57393` indicates belated external release on PBX disconnect.
- i. **Error Type 1793:** DS1 Interface circuit pack or media module is out-of-service. Look in the error log:

If port is on	Look in
TN767 DS1 Board	DS1-BD
TN464 UDS1 Board	UDS1-BD
DS1 Interface Media Module	MG-DS1

- j. **Error Type 2305** indicates that a signaling change was detected by the PBX trunk circuit pack or media module which is inconsistent with the present state of the trunk.

- k. **Error Type 3840:** Port Audit and Update test (#36) failed due to an internal system error. Enter `status trunk` to verify the status of the trunk. If the trunk is out-of-service, enter `release trunk` to put it back to in-service. Retry the test command.

Demand test descriptions and error codes

Investigate tests in the order presented. By clearing errors associated with the first test, errors generated from other tests may also be cleared. Click on the link to see the full description of the test, error codes, and recommended actions.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND ¹
NPE Crosstalk Test (#6)		X	ND
Conference Circuit Test (#7)		X	ND
Port Audit And Update Test (#36)	X	X	ND

1. D = Destructive; ND = Nondestructive

DID-TRK (Direct Inward Dial Trunk)

MO Name in Log	Alarm Level	Initial Command to Run	Full Name of MO
DID-TRK	MAJ ¹ MIN	<code>test port location 1</code>	DID Trunk
	WRN	None	

1. A MAJOR alarm on a trunk indicates that alarms on these trunks are not downgraded by `set options` and that at least 75 percent of the trunks in this trunk group are alarmed.

Many trunk problems are caused by incorrect settings of parameters on the trunk group administration screen. Settings must be compatible with the local environment and with parameter settings on the far end. Refer to the *Administering Avaya Aura™ Communication Manager*, for information about how to administer trunks. Refer to your Avaya representative for the correct settings for administrable timers and other parameters on a country-by-country basis.

Direct Inward Dial (DID) trunks coming from the Central Office (CO) allow outside parties to call directly to an extension in the system. DID Trunk circuit packs include:

TN753	United States
TN2146	Belgium and the Netherlands
TN2139	Italy
TN 436	Australia
TN459	United Kingdom

DID trunk circuit packs and the MM711 Media Module support eight incoming-only ports. Each port provides an interface between the 2-wire analog CO line and the 4-wire TDM bus on the switch.

Not all tests that run on circuit packs are applicable to media modules. These tests will abort with error code 1412. This error can be ignored.

DID Trunk Operation

The DID port receives three to seven digits from the CO that are used to directly connect an outside caller to the called station without assistance from an attendant. For each call, the CO switch signals the system by opening and closing individual DID loops (one of the eight ports), causing the starting or stopping of loop current.

DID Trunk Testing

The system uses technician-invoked tests of on-board circuitry to diagnose the health of the trunk. These are described in the following sections. Additionally, inline testing which can generate errors, is performed while a call is in progress. See the Error Log table for a description of these errors. These errors may be reproduced by placing a call on the trunk and checking the error log.

Problems detected during signaling may be caused by off-board faults in the CO switch or connections for which a Warning alarm is raised.

Before a maintenance test can be run on a port, the port must be idle. If an incoming call seizes a port that is being tested, the test will abort and the incoming call will proceed.

Ports Out-of-Service without Errors or Alarms

A common trouble on DID trunks that produces no errors or alarms occurs when the CO busies out (disconnects) the port. This situation occurs when the CO thinks there are problems with the DID port. In this case, no incoming calls will be possible through this port. This may result in complaints from outside callers trying unsuccessfully to call in. This problem can be diagnosed by listing measurements on lightly used trunks. If a particular port is detected as idle, a call to the CO will be necessary to get the connection back in service.

Error log entries and recommended actions

					2 of 2

1. Major alarms may be downgraded to Warning alarms based on the value used in **set options**.

Notes:

- a. **Error Type 0:** Run the short test sequence first. If every test passes, run the long test sequence.
- b. **Error Type 1, Aux Data - Any:** the tone detector timed out waiting for digits. Change wink/immediate-start parameter to wink/immediate-start and rotary/tone-dial parameters.
 1. Verify trunk administered wink/immediate-start parameter.
 2. Test trunk using BUTT set.

3. Refer problem to CO.
- c. **Error Type 1, Aux Data 57476:** Rotary dial before wink occurs when the CO starts dialing before the PBX sends wink on a wink-start trunk.
 1. Verify trunk administered wink/immediate-start parameter.
 2. Refer problem to CO.
- d. **Error Type 1, Aux Data 57477:** Rotary dial too early occurs when the CO starts dialing too soon after seizure on an immediate-start trunk.
 1. Verify trunk administered wink/immediate-start parameter.
 2. Refer problem to CO.
- e. **Error Type 1, Aux Data 57483:** Rotary dial pulse during wink occurs when the CO sends rotary dial digits too soon after seizure on a wink-start trunk.
 1. Verify trunk administered wink/immediate-start parameter.
 2. Refer problem to CO.
- f. **Error Type 15:** software audit error that does not indicate a hardware malfunction. Run short test sequence, and investigate any associated errors.
- g. **Error Type 130:** the circuit pack or media module has been removed or has been insane for more than 11 minutes. To clear the error, reinsert or replace the circuit pack or media module.
- h. **Error Type 257, Aux Data 57472:** Rotary dial pulse on-hook longer than 105 msec, the break between rotary pulses is too long.
 1. Test trunk by performing an incoming test call.
 2. Refer problem to CO.
- i. **Error Type 257, Aux Data 57473:** Rotary dial rate below 8 pulses/sec, more than 135 msec between two successive breaks.
 1. Verify trunk administered interdigit-timing parameters.
 2. Refer problem to CO.
- j. **Error Type 257, Aux Data 57474:** Rotary dial rate above 12 pulses/sec, less than 75 msec between two successive breaks.
 1. Verify trunk administered interdigit-timing parameters.
 2. Refer problem to CO.
- k. **Error Type 257, Aux Data 57475:** Digit detection, CO is starting new rotary dial digit within 150 msec of previous digit.
 1. Verify trunk administered interdigit timing parameters.
 2. Refer problem to CO.

l. Error Type 513, Aux Data -57392: Loop current active, CO is not releasing trunk after PBX disconnect. Occurs when the PBX end drops first and the CO does not release the trunk within 4 minutes.

1. Verify the interface to the network with a hand telephone set. If calls are placed correctly, then refer problem to the CO.
2. If unable to place calls or this equipment is not available, check the status on port using `status trunk`. If active but not connected, disconnect bridging clips at the network interface. Check status on the trunk. If trunk went idle, then replace clips. If trunk is still active but unable to place calls, refer problem to the CO.

m. Error Type 513, Aux Data 57393: Late CO trunk release occurs only after the occurrence of Error Type 513. The CO released the trunk 4 minutes after the PBX dropped the call. This event decrements the severity (error count) of Error Type 513, or may mean the problem related to Error Type 513 has been fixed.

Verify that Error Type 513 does not occur again. Refer to Error 513.

n. Error Type 1793: Incomplete Dial timer expired. Applies only to the TN459 and indicates a problem with incoming dialing stream. Refer the problem to the CO.

DIG-BD (Digital Line Circuit Pack)

MO Name in Log	Alarm Level	Initial Command to Run	Full Name of MO
DIG-BD	MIN WRN	<i>test board location</i>	Digital Line circuit pack

See [XXX-BD \(Common Port Circuit Pack/Media Module\)](#) for circuit pack-level errors.

See [DIG-LINE \(Digital Line\)](#) for related line information.

DIG-IP-S (Digital IP Station)

MO Name in Log	Alarm Level	Initial Command to Run	Full Name of MO
DIG-IP-S	WRN	<code>test station extension</code>	Digital IP Station

The DIG-IP-S MO represents Softphone and Avaya 46XX phones. Softphone has some DCP maintenance capability in the form of audits, updates, error log entries, and tests. Avaya 46XX IP phones communicate to the switch via an IP LAN and emulate DCP signaling carried over TCP.

The IP phone is not attached to a port board. Insertion of the phone is driven by successful registration of the endpoint, not by board insertion. It is maintained via a set of explicit TCP/IP ping requests and errors reported by the User Manager software, which terminates the H.323 signaling portion of each endpoint. The MO follows standard maintenance methodology and supports `test`, `busyout`, `release` and `status` commands.

A registered extension has a port number or ID in the form of *SNNNNN*, where *N* is a digit from 0–9. This ID indicates that the extension is a virtual port and a station.

Note:

A port number or ID of *SNNNNN* does not necessarily indicate that the extension is registered. A registered extension retains the *SNNNNN* port number or ID, even if the extension later unregisters.

Error log entries and recommended actions

Table 83: DIG-IP-S Error Log Entries 1 of 2

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Recommended Action
0	0	Any	Any		<code>test station extension</code>
1 (a)		Registration Status Inquiry (#1372)	WRN	OFF	
18 (b)	0	<code>busyout port station</code>	WRN	OFF	<code>release port station</code>
257 (c)		Signaling Path PING test (#1373)	WRN	OFF	
513 (d)	Any	Digital Station Audits Test (#17)	WRN	OFF	<code>test port station</code>
					<i>1 of 2</i>

Table 83: DIG-IP-S Error Log Entries 2 of 2

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Recommended Action
1281 (e)	Any	Digital Station Audits Test (#17)	WRN	OFF	<i>test port station</i>
1537 (f)	40968		WRN	OFF	<i>test port station</i>
1793 (g)			WRN	OFF	
2305 (h)	Any				
2817 (i)		Station Hyperactivity			
					2 of 2

Notes:

- a. **Error Type 1:** reports the registration status of the endpoint. If Communication Manager software claims the endpoint is registered and receives keep-alive handshakes from the endpoint, the test passes. If keep-alive handshaking has failed, the test fails. If the user has intentionally un-registered from the S8700-series server, the station is now basically an AWOH station and is no longer being maintained. No tests are run for this station.
- b. **Error Type 18:** the port/station is busied out by maintenance personnel. Make sure the port/station is released from busy via *release port | station* (IP terminal only).
- c. **Error Type 257** tracks failures of the signaling path PING test. The test attempts to send a PING packet to the endpoint IP address, as reported during registration. The PING packet originates with the C-LAN board through which the endpoint is registered. If the PING response packet is received, the test passes. If the PING response packet times out, the test fails.
- d. **Error Type 513** indicates that the terminal failed to respond to the ID Query request. This implies that there is something wrong with the terminal or the communication path. (IP terminal only).
- e. **Error Type 1281** indicates that the terminal is reporting a bad state of health (IP terminal only).
- f. **Error Type 1537** indicates that the link has gone down between the terminal and its gateway to the switch. This likely means that the terminal has unregistered (IP terminal only).
- g. **Error Type 1793:** indicates the IP station has registered with a Survivable Remote Server. Follow standard practices to repair the primary server, or network failure.
- h. **Error Type 2305** indicates that there was an unsolicited Link Reset even though switch software believed the terminal to be functional and in service. This error can be ignored if no user complaints are received (IP terminal only).

- i. **Error Type 2817** tracks failures of the port hyperactivity counter. If a port generates more than 50 uplink CCMS messages within 10 seconds, the port is taken out-of-service for 30 seconds. Even though the Softphone actually signals over a TCP/IP link, DCP CCMS messages received over the TCP link are counted as regular CCMS uplinks and can cause the station to be marked as hyperactive.

Demand test descriptions and error codes

Investigate tests in the order presented. By clearing errors associated with the first test, errors generated from other tests may also be cleared. Click on the link to see the full description of the test, error codes, and recommended actions.

Digital Station Lamp Update (#16)	X	X	ND
Digital Station Audits Test (#17)		X	ND

1. D = Destructive; ND = Nondestructive

DIG-LINE (Digital Line)

MO Name in Log	Alarm Level	Initial Command to Run	Full Name of MO
DIG-LINE	MIN	<code>test port location long</code>	Digital Line
	WRN	<code>test port location</code>	

DIG-LINE maintenance monitors and tests ports on digital line circuit packs or digital line media modules and on hardware administered as a digital station on those ports. These include stations with only a digital phone and stations with a digital phone linked to a data module.

Standalone data modules and data adaptors in standalone mode are covered by [PDMODULE \(Processor Data Module\)](#).

Circuit pack maintenance is covered by [DIG-BD \(Digital Line Circuit Pack\)](#), the strategy for which is described in [XXX-BD \(Common Port Circuit Pack/Media Module\)](#).

The following circuit packs support digital lines:

Table 84: Digital Line Circuit Packs

Code	Ports	Type	Companding	Endpoints
TN754	8	4-wire DCP	mu-law	7400 series digital voice terminals, attendant consoles, 510D personal terminals, MT515 BCTs, DCP data modules
TN754B	8	4-wire DCP	A-law/mu-law	
TN2181	16	2-wire IDCP	A-law/mu-law	
TN2224B/CP	24	2-wire IDCP	A-law/mu-law	
TN2136	8	2-wire IDCP	A-law/mu-law	Data Adaptors (DA), Italtel Digital Telephone Models 1 and 2 (IDT1/2).
TN2181	16	2-wire IDCP	A-law/mu-law	
TN2224B/CP	24	2-wire IDCP	A-law/mu-law	

Each digital line port supports two 64 kbps information channels (primary and secondary) and one 8kbps signaling channel. Digital voice terminals always use the primary information channel, and only one voice terminal can be connected to each port. The secondary information channel can be used to connect a data terminal via a Digital Terminal Data Module (DTDM) or a Data Adaptor (DA). All other devices currently supported by Digital Line circuit packs communicate on the primary information channel. [Figure 14: Digital Line Connectivity](#) shows examples of digital line connectivity.

Use only the TN754B or TN2136 circuit packs in out-of-building applications.

The TN2181 and TN2224B/CP support both modes as shown in [Figure 14: Digital Line Connectivity](#) and [Figure 15: Digital Line Connections](#).

Figure 14: Digital Line Connectivity

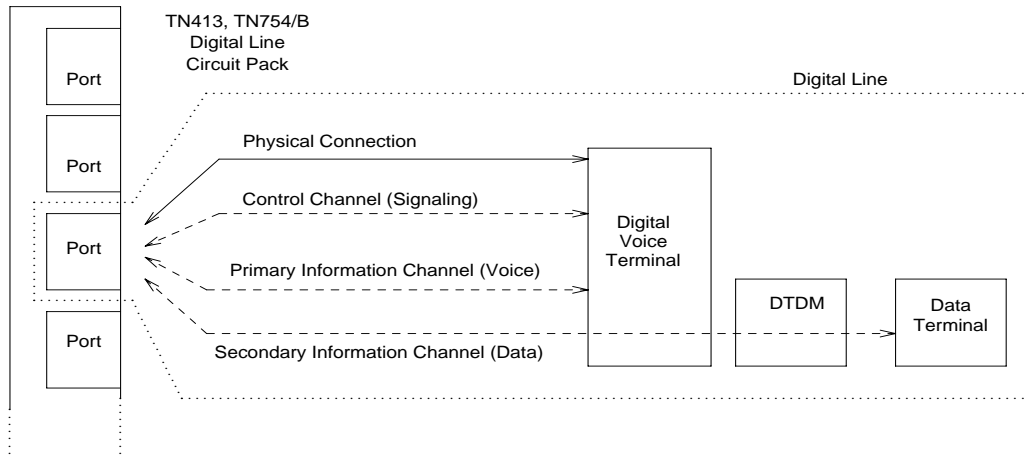

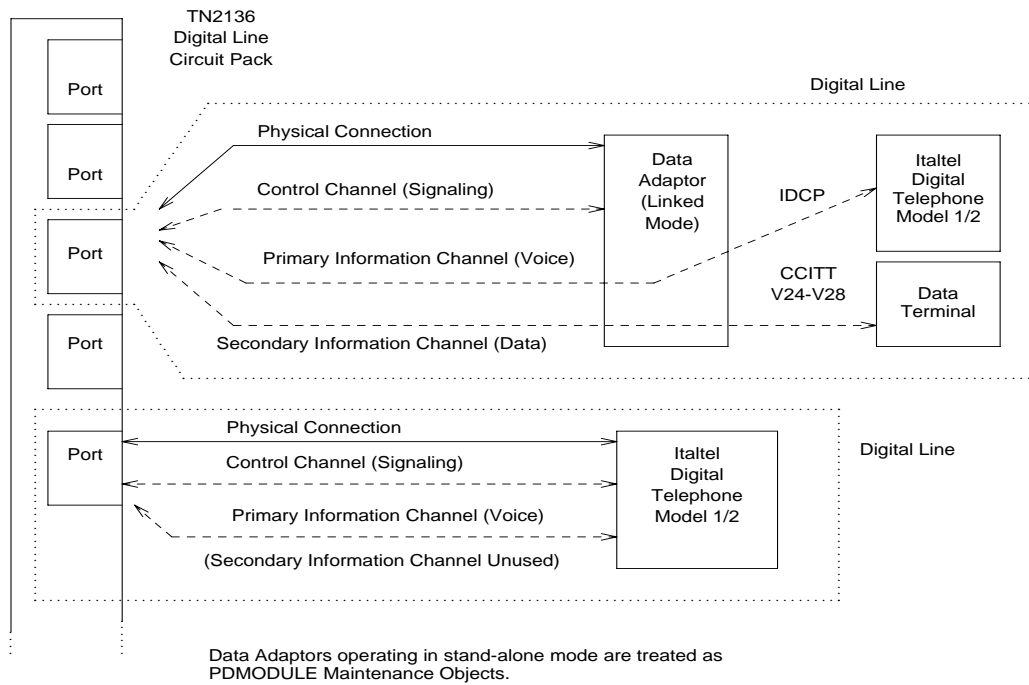

Figure 15: Digital Line Connections

Only 2-wire Italtel Digital Telephone Models 1 and 2 (IDT1/2) or DAs can directly connect to a TN2136 circuit pack. Avaya DCP (4-wire) digital voice terminals and data modules can connect to these circuit packs via Italtel's 2/4-wire adapter. DAs operate in either of 2 modes, and are covered by different MOs:

DA Mode	Administered as:	Endpoint	MO
Standalone	PDM	Data endpoint only	PDMODULE
Linked	DTDM	IDT1/2 and optional data terminal	DIG-LINE

Service States

Digital line maintenance interacts with digital line circuit pack (DIG-BD), or with digital line media module (MG-DCP) maintenance. The health of the digital-line circuit pack or media module can affect the results of DIG-LINE testing. Keep this in mind when investigating digital-line problems.

It is sometimes important to know the service state of a station. These service states apply to digital-line stations:

Out-of-Service state	The port, and thus the station, have been removed from service. The busyout command puts the port in the out-of-service state.
Ready-for-Service state	The port on the circuit pack or media module has been put into service, but the voice terminal has not yet established signaling communications with the port.
In-Service state	The voice terminal has established signaling communications with the port, and the system is ready to process calls to and from that station. A terminal in the ready-for-service state will progress to the in-service state if it is functioning normally. It can also be forced into the in-service state by going off-hook.

Downloading Terminal Parameters

This section explains how maintenance software interacts with terminal parameter downloading.

For Systems Supporting Circuit Packs

Terminal Types:

Software can interact with the following terminal types:

- | 84xx multi button digital voice terminals (8403D01A, 8410B, 8410D02A, 8434D01A) with optional expansion module.
- | 603A1 and 603D1 Callmaster terminals for telemarketing applications.
- | 302B1 and 302C1 attendant console.

Circuit Packs:

- | 8400x, 302B1 Terminals
 - | TN754 (4-wire, mu-law)

Note:

Minimum usable vintage for 8410D and 8434D terminals - V11

- | TN413 (4-wire, A-law)
- | TN754B (4-wire, A-law/mu-law selectable)
- | TN2177 (2-wire, 16-port, A-law/mu-law selectable)
- | TN2181 (2-wire, 16-port, A-law/mu-law selectable)
- | TN2224 (2-wire, 24-port, A-law/mu-law selectable)
- | 603A1/D1 Terminals
 - | TN754 (4-wire, mu-law),
 - | TN413 (4-wire, A-law)
 - | TN754B (4-wire, A-law/mu-law selectable)

For Systems Supporting Media Modules

The MM712 Media Module supports 8410D and 8434D terminals (2-wire, 8-port, A-law/mu-law selectable).

Programmable Terminals

The following parameters are downloaded to programmable terminals.

Table 85: Parameters Downloadable to Programmable Terminals

Parameter	Scope	Terminal
International Flags (A-law/mu-law, Display Mode, DLI Voltage level)	System level	84xx, 603x, 302B1
Primary Levels (Transmission & Sidetone)	System level	84xx, 603x, 302B1
Adjunct Levels (Transmission & Sidetone)	System level	84xx
Handset Expander Option	System level	84xx
Administrable Options (Speakerphone & Mute Button)	Per-terminal	84xx
Administrable Softkeys	Per-terminal, System level	8410D, 8434D

Nonvolatile Memory

Nonvolatile memory stores downloadable parameters in programmable terminals. Once the terminal is downloaded, it is not necessary to download it again, even if power is removed from the terminal. If nonvolatile memory fails with power still present, the terminal reverts to its default factory settings except for its A-law/mu-law companding settings which are stored in RAM. If power is removed after the nonvolatile memory fails, the terminal reverts to its factory default settings.

Note:

The mu-law companding mode is assigned as a default setting at the factory. For the United States, a programmable terminal can place calls even though it has not been downloaded from the system.

Download Actions

There are several different scenarios that cause a terminal to be downloaded. These can occur as part of background maintenance activity or on demand from the system access terminal or from a station.

For the following background actions, the terminal downloads automatically if a download retry flag for the terminal is set in software. This flag is set:

- 1 At boot time when translation is loaded
- 1 When translation that affects the parameters of a terminal is changed as part of system administration action
- 1 When a port is inserted in software as a result of board insertion or translation change

Automatic Download Actions

This section describes download actions that occur automatically.

System Reboot/Restart

A global download action is started when periodic maintenance tests start after a system reboot/restart regardless of whether the parameters have been downloaded previously.

Periodic Tests

If the download flag is still set when periodic tests are run on a terminal, a download action will occur. This operation is required in case a terminal could not be downloaded previously either:

- 1 Because it was off-hook at the time the system first booted
- 1 Because the terminal was off-hook at the time translation associated with downloadable parameters was changed

Note:

It may take more than 1 hour for periodic tests to reach the terminal that needs to be downloaded.

Terminal Administration

A downloadable terminal is automatically downloaded when translation changes associated with downloadable parameters are made as part of system administration. As shown in [Table 85: Parameters Downloadable to Programmable Terminals](#), these changes can be for a specified terminal or may be system-wide. If the change is for system-level parameter, a background global update request is made to download all programmable terminals.

This global update may take more than an hour for a system with several thousand programmable terminals.

Port Insertion

Whenever maintenance software initiates a request to place a port into service, a terminal download action is started on that terminal if that terminal is programmable. This port insertion action occurs under the following circumstances:

- 1 A digital line circuit pack or media module that is physically inserted into the system has ports currently administered for programmable terminals.

If more than 20 port insertion requests are received within a few seconds, a global download request is started up as a background task. This action updates all programmable terminals instead of just those being inserted. This is done to avoid system overload for situations where there is massive board insertion. This could occur when connectivity to an PN is re-established after that PN was down.

- 1 A station port is added to the system by `add station` or `change station`.
- 1 A TTI port is activated.

Audits

As part of periodic maintenance, the hardware status audit test queries programmable terminals to determine what levels and/or options are being used. If the reported values are not equal to the administered values, the system will initiate a terminal download action. This audit does NOT check the parameters used for softkeys.

Activation of TTI

A terminal is downloaded automatically when it is activated using the Terminal Translation Initialization feature. Therefore, no special user actions are required for TTI.

Note:

Plugging the station cord into a terminal does not automatically cause the terminal to be downloaded. If this terminal has factory defaults or if the terminal has been previously downloaded with parameters different from those desired, use one of the following demand download actions to download the terminal.

Demand Download Actions

Busyout/Release Command

A maintenance demand busyout/release request for a station causes the terminal to be downloaded regardless of its previous download status.

Feature Access Code

A Refresh Terminal Parameters Feature Access Code can be used to request a terminal download action. When this code is followed by a pound sign (#), the programmable parameters for the current terminal are downloaded when the terminal goes on-hook. When this code is followed by an extension, the programmable parameters for the specified station are downloaded.

Assign the Refresh Terminal Parameters Feature Access Code on the Feature Access Codes form.

A confirmation is returned if the download request is accepted. A busy tone is returned if the request is made from a different station when the target station is off-hook.

Note:

For systems supporting circuit packs, the first three green call appearance LEDs on the 84xx 603x terminal will be turned on for three seconds if the station was successfully downloaded as a result of an entry of a Refresh Terminal Parameters Facility Access Code. This is not true for the 302B1 terminal.

There is no visible display on a station for the other background or demand download actions. Use `status station` and `status attendant` forms to check the download status of a specified terminal.

Parameter Download Status

The `status station` and `status attendant` forms display the current download status of individual 84xx, 603, and 301B1 terminals in the **Download Status** field. Possible download states are:

Status	Explanation
Complete	Terminal successfully downloaded sometime in the past.
Pending	System waiting to download the terminal. This may require the execution of a background periodic test which could take more than an hour. A demand download as previously described may also be used to initiate an immediate download.
Not Applicable	Not a programmable terminal.

Possible reasons for a terminal not being downloaded include:

- 1 Terminal is off-hook.
- 1 Terminal detected a bad checksum.
- 1 Terminal detected a bad or missing EEPROM (refer to error log).
- 1 Terminal is busy programming data from a previous PROGRAM message.
- 1 Terminal is in the Programming Disabled state.
- 1 Terminal is in the Local Program Options mode.
- 1 Terminal is disconnected or out of service (use `status station`).

Error log entries and recommended actions

3840 (r) (s)	40965 40989				
3841 (t)	41029				
					2 of 2

1. Major alarms may be downgraded to Warning alarms based on the value used in `set options`.

Notes:

- a. **Error Type 0:** Run the short test sequence first. If every test passes, run the long test sequence.
- b. **Error Type 1, Aux Data 40987** could indicate a noisy port or link. This is an off-board problem detected by the port circuit. Check for defective wiring, a defective voice terminal,

or move voice terminal closer to the switch (in terms of feet of wire from the jack to the switch). If the problem still exists, replace the circuit pack. Once the problem is resolved, the alarm is retired after a predetermined amount of time.

- c. **Error Type 1, Aux Data 1 - 20** occurs when at least 15 off-board problems with the link to the terminal have been detected. When an error with the link is detected, an on-board counter is incremented.

The user could experience a noisy port or link. This is an off-board problem detected by the port circuit. Check for defective wiring, a defective voice terminal, or move voice terminal closer to the switch (in terms of feet of wire from the jack to the switch). If the problem still exists, replace the circuit pack. Once the problem is resolved, the alarm is retired after a predetermined amount of time.

- d. **Error Type 18:** the port in question is busied out by maintenance personnel. Use *release port location* to release the port from busyout.
- e. **Error Type 130:** the circuit pack or media module has been removed or has been insane for more than 21 minutes. To clear the error, reinsert or replace the circuit pack or media module.
- f. **Error Type 257:** problems transmitting to the voice terminal. This can be caused by defective wiring, which can cause varying degrees of problems on different types of sets. Sets such as the 7410 appear to be more susceptible to wiring problems than other sets. This is usually an on-board problem and can be ignored if no user complaints are received.
- g. **Error Type 767:** a favorable response was received from running the [Digital Line Electronic Power Feed Test \(#11\)](#). No action is necessary. This alarm is resolved with the passing of time.
- h. **Error Type 769, Aux Data 40963:** unfavorable response was received from the [Digital Line Electronic Power Feed Test \(#11\)](#). See the test for repair procedures.
- i. **Error Type 769, Aux Data 40988:** the EPF/PTC circuit has been turned off due to an overcurrent condition.

For TN754 vintage 13 or earlier and TN413, the EPF circuit senses an overcurrent condition at the voice terminal. Check for a short in the wiring, a damaged jack, an incorrect type of voice terminal, or a defective voice terminal.

For TN754 vintage 14 or later, TN754B and TN2136, the PTC will open if there is a short on the power line for 1/2 second or longer. The voice terminal is probably not operating properly. Unplug the voice terminal for 30 seconds and then plug it back in. If the voice terminal still does not operate, then check for a short in the wiring, a damaged jack, an incorrect type of voice terminal, or a defective voice terminal.

Once the problem has been resolved, it may take up to 1 hour for the alarm to clear. If the problem can be resolved by one of the previous steps, then replace the circuit pack or media module.

- j. **Error Type 769, Aux Data 40989:** the CM software sends an EPF query to the port board for a particular port. The board returns the failure message 40989. This error is caused if the board is busy on TN2224CP HV4 FV15. 40989 represents a message from the board that

the EPF is off for that port. This means that the power for this particular port is not working. As a recovery strategy, you may busy out or release the port and then re-test the port. However, if the failure still continues, replace the board.

- k. **Error Type 1026:** There is a problem with the voice terminal EEPROM. When the voice terminal is repaired the alarm will be resolved with the passing of time.
- l. **Error Type 1537:** an off-board warning was generated due to a problem with the link to the voice terminal. This can be ignored if no user complaints are received. Otherwise, make sure the voice terminal is connected, check for defective wiring, check for a defective voice terminal, and move voice terminal to a jack that is closer to the switch (in terms of feet of wiring between the jack and the switch). If the problem still exists, replace the circuit pack or media module. Once the problem has been resolved, the alarm will be retired after a predetermined amount of time.
- m. **Error Type 2304:** Internal system error. No action is necessary.
- n. **Error Type 2305, Aux Data 32770:** This indicates that the station went off-hook while it was in the ready-for-service state. Use `status station` to determine the state of the station. The off-hook should have moved the station to ready-for-service. No action is necessary.
- o. **Error Type 2305, Aux Data 40967:** an off-board warning was generated due to some problem with the link to the voice terminal. This can be ignored if no user complaints are received. Otherwise, make sure the voice terminal is connected, check for defective wiring, check for a defective voice terminal, and move voice terminal to a jack that is closer to the switch (in terms of feet of wiring between the jack and the switch). If the problem still exists, replace the circuit pack or media module. Once the problem has been resolved, the alarm will be retired after a predetermined amount of time.
- p. **Error Type 2817:** Port Level Hyperactivity. Fifty or more CCMS uplink messages were received from the port within ten seconds. The user is taken out of service for a short interval of time (default 30 seconds).
- q. **Error Type 3585:** an attempt to execute a firmware download of a DCP terminal has failed. The DCP terminal must be replaced before the firmware download can be executed successfully. Replace the DCP terminal and re-execute the firmware download.
- r. **Error Type 3840, Aux Data 40965:** No terminal is connected to the Digital Line board. No maintenance action is required.
- s. **Error Type 3840, Aux Data 40989:** the Electric Power Feed (EPF) is on with no load on it. No action is necessary.
- t. **Error Type 3841:** The circuit pack's or media module's message buffer is full. This may be caused by having many display phones with heavy traffic connected to the circuit pack or media module. No action is necessary.

Demand test descriptions and error codes

Investigate tests in the order presented. By clearing errors associated with the first test, errors generated from other tests may also be cleared. Click on the link to see the full description of the test, error codes, and recommended actions.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND ¹
Digital Terminal Remote Looparound Test (#1201)		X	D
Local Loop Test (#13)		X	ND
GPP NPE Crosstalk Test (#9)		X	ND
Digital Line Electronic Power Feed Test (#11)		X	ND
Digital Station Lamp Update (#16)	X	X	ND

See [XXX-BD \(Common Port Circuit Pack/Media Module\)](#).

DIOD-DS1 (DS1 DIOD Trunk)

MO Name in Log	Alarm Level	Initial Command to Run	Full Name of MO
DIOD-DS1	MAJ ¹	<code>test trunk grp#/mem# 1</code>	DS1 DIOD Trunk
	MIN		
	WRN	<code>test trunk grp#/mem#</code>	

1. A Major alarm on a trunk indicates that alarms on these trunks are not downgraded by `set options` and that at least 75 percent of the trunks in this trunk group are alarmed.

Note:

Many trunk problems are caused by incorrect settings of parameters on the trunk group administration screen. Settings must be compatible with the local environment and with parameter settings on the far end. Refer to *Administering Avaya Aura™ Communication Manager* for information on how to administer trunks. Refer to your Avaya representative for the correct settings for administrable timers and other parameters on a country-by-country basis.

A DS1 Direct Inward Outward Dialing (DIOD) trunk provides a link for digitized voice or data communications between the system and a central office switch. There are two types of DS1 interfaces:

- 1 24 DS0 channels on a 1.544-Mbps link
- 1 31 DS0 channels + 1 framing channel on a 2.048-Mbps link

Note:

32-channel mode is supported only on TN464C and higher suffix circuit packs.

The DS1-DIOD MO monitors and maintains a DIOD trunk port on a TN464 UDS1 Interface circuit pack. See [UDS1-BD \(UDS1 Interface Circuit Pack\)](#) for more information about this circuit pack. The DS1 circuit pack supports low-level CO trunk signaling interfaces for both ground-start and loop-start trunks. This maintenance strategy covers the inline errors log, initialization tests, periodic tests, scheduled tests, demand tests, and alarm resolution and escalation.

Three trunk service states are specified by DS1 DIOD trunk maintenance:

out-of-service	The trunk is in a deactivated state and cannot be used for either incoming or outgoing calls.
in-service	The trunk is in an activated state and can be used for both incoming and outgoing calls.
disconnect (ready-for-service)	The trunk is in an activated state but can only be used for an incoming call.

2562 (m)	16665				
2817 (n)	52992				
3840 (o)		Port Audit and Update (#36)			
					2 of 2

1. This alarm is raised when the `Base Tone Generator` field is 4 (Italy) on the System-Parameter Country screen. This alarm is MINOR unless 75% or more trunks in this trunk group are out of service, then the alarm is upgraded to a MAJOR alarm.
2. Major alarms may be downgraded to Warning alarms based on the value used in `set options`.

Notes:

a. **Error Type 0:** Run the short test sequence first. If every test passes, run the long test sequence. Refer to each test's description, and follow its recommended procedures.

b. **Error Type 1**

Aux Data 57408: No tip ground is detected on an outgoing call.

Aux Data 57476: Rotary Dial before Wink.

Aux Data 57477: Rotary Dial pulse too early.

Aux Data 57485: Wink too short for a valid signal.

Aux Data 57487: PBX could not get "loop close" signal.

The DS1 Interface circuit pack detected a hardware fault. These errors will cause the DS1 CO Trunk Dial Tone test (#314) to run and are only considered a problem if the Dial Tone test fails (in which case Error Type 1025 will also show up). In this case, the trunk may be put in the ready-for-service state (shown as "disconnected" by the status command), which allows only incoming calls. Run the [DS1 CO Trunk Dial Tone Seizure Test \(#314\)](#) and follow the procedures.

c. **Error Type 15:** software audit error that does not indicate any hardware malfunction. Run short test sequence, and investigate any errors.

d. **Error Type 18:** the trunk has been busied out and is in the out-of-service state. No calls can be made on this trunk except Facility Access Test Calls. For details, see [Facility test calls](#) in *Maintenance Procedures (03-300432)*.

e. **Error Type 130:** the circuit pack has been removed or has been insane for more than 11 minutes. To clear the error, reinsert or replace the circuit pack.

- f. **Error Type 257:** The DS1 Interface circuit pack detects a hardware fault. Aux Data 57392 indicates no external release on PBX disconnect.
- g. **Error Type 513:** The DS1 Interface circuit pack detects a hardware fault. Aux Data 57393 indicates belated external release on PBX disconnect.
- h. **Error Type 769:** The DS1 Interface circuit pack detects a hardware fault. Aux Data 57484 indicates fault is detected on tip/ring.
- i. **Error Type 1025:** The DS1 Interface circuit pack detects a hardware fault, and Aux Data contains 51200, port is unavailable. Run the [DS1 CO Trunk Dial Tone Seizure Test \(#314\)](#).
- j. **Error Type 1793:** DS1 Interface circuit pack is out-of-service. Look for UDS1-BD errors in the error log if the port is on a TN464 UDS1 board. See [UDS1-BD \(UDS1 Interface Circuit Pack\)](#) for details.
- k. **Error Type 2049:**

Aux Data 57473 – Rotary dial rate below 8 pulses per second.

Aux Data 57474 – Rotary dial rate above 12 pulses per second.

Aux Data 57475 – Rotary Dial interdigit time is too short.

The DS1 interface circuit pack detects a hardware error on the DS1 DIOD trunk. The trunk cannot communicate with the far end because it is unable to interpret digits sent from the far-end switch. Check with the far-end switch or Operating Company for proper trunk connection.

- l. **Error Type 2305:** Recorder message, trunk could not be seized (Aux Data 50944). Run [DS1 CO Trunk Dial Tone Seizure Test \(#314\)](#) and follow the outlined procedures.
- m. **Error Type 2562:** Retry Failure error. This error is logged only. It is not a hardware failure and hence does not start any testing or generate any alarms. This error comes from Communication Manager and is generated when a second attempt (retry) to seize an outgoing trunk fails.
- n. **Error Type 2817:** Glare error. This error is logged only. It is not a hardware failure and hence does not start any testing or generate any alarms. This error is the result of a simultaneous seizure of a 2-way trunk from both the near and far ends. Attempt to place the call again. If the error persists, execute the [DS1 CO Trunk Dial Tone Seizure Test \(#314\)](#), and follow those procedures.
- o. **Error Type 3840:** The [Port Audit And Update Test \(#36\)](#) failed due to an internal system error. Enter `status trunk` to verify the status of the trunk. If the trunk is out-of-service, then enter `release trunk` to put it back into in-service. Retry the test command.

Demand test descriptions and error codes

Investigate tests in the order presented. By clearing errors associated with the first test, errors generated from other tests may also be cleared. Click on the link to see the full description of the test, error codes, and recommended actions.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND ¹

Port Audit And Update Test (#36)	X	X	ND

1. D = Destructive, ND = Nondestructive

DIOD-TRK (DIOD Trunk)

MO Name in Log	Alarm Level	Initial Command to Run	Full Name of MO
DIOD-TRK	MAJ ¹ MIN WRN	<code>test port location</code>	DIOD Trunk

1. A MAJOR alarm on a trunk indicates that alarms on these trunks are not downgraded by `set options` and that at least 75 percent of the trunks in this trunk group are alarmed.

Many trunk problems are caused by incorrect settings of parameters on the trunk group administration screen. Settings must be compatible with the local environment and with parameter settings on the far end. Refer to the *Administering Avaya Aura™ Communication Manager*, for information about how to administer trunks. Refer to your Avaya representative for the correct settings for administrable timers and other parameters on a country-by-country basis.

Direct inward and outward dial (DIOD) trunks are 2-wire analog lines to the CO which support the following services:

- 1 Both incoming and outgoing CO calls
- 1 DID trunk
- 1 DID trunk and 1-way outgoing DIOD

TN429 DIOD trunk circuit packs and MM711 Analog Media Modules provide eight ports for loop-start CO trunks and serve as an interface between the 2-wire analog CO line and the 4-wire TDM bus on the switch.

Not all tests that run on circuit packs are applicable to media modules. These tests will abort with error code 1412. This error can be ignored.

Loop Start Operation

Idle State: Tip = ground, Ring = CO Battery

Outgoing Call

1. PBX Off-Hook (Seize Message): Closes the Tip-Ring Loop
2. CO Response: DC loop current + Dial tone
3. PBX On-Hook (Drop Message): Open Tip-Ring loop, no loop current
4. CO Response: CO goes to idle state (see Note)

Incoming Call

1. CO Applies Ringing Voltage
2. PBX Response: Detect ringing current
3. PBX Off-Hook (Answer Message): Close loop
4. CO Response: Trip ringing, provide loop current
5. PBX On-Hook (Drop Message): Open Tip-Ring loop, no loop current
6. CO Response: CO goes to idle state (see Note)

Direct Inward Dialing (DID) (Loop Start)

1. CO Applies Ringing Voltage
2. PBX Response: Detect ringing current and close loop
3. CO Response: Send DTMF digits
4. PBX Response: Acknowledge of Number dialed and open loop
5. PBX Off-Hook (Answer Message): Close loop
6. CO Response: Trip ringing, provide loop current
7. PBX On-Hook (Drop Message): Open Tip-Ring loop, no loop current
8. CO Response: CO goes to idle state (see Note)

Note:

CO does not normally provide an On-Hook (Disconnect) signal.

Error log entries and recommended actions

3585 (g)	57424				
					2 of 2

1. Major alarms on this MO may be downgraded to Warning alarms based on the value in `set options`. If the Minor alarm is not downgraded by `set options` values, the Minor alarm is upgraded to a Major alarm if 75 percent of the trunks in this trunk group are alarmed.

Additional Information:

- a. **Error Type 0:** Run the short test sequence first. If every test passes, run the long test sequence. Refer to each test's description, and follow its recommended procedures.
- b. **Error Type 15:** software audit error and does not indicate any hardware malfunction. Run the short test sequence, and investigate associated errors.
- c. **Error Type 769, Aux Data 57392** are inline errors that have no specific test associated with them. The CO is not releasing after the call is dropped from the PBX end. After several occurrences, an off-board warning alarm is generated. Refer the problem to the CO.
- d. **Error Type 2561, Aux Data 57345:** Single polarity ringing current. This is an inline error that has no specific test associated with it. This error results from abnormal ringing current, but does not prevent the incoming call from being accepted. This error code is logged for information purposes only and does not cause additional testing to occur. One cause could be that the reverse current detector associated with the port is failing. (Will not be detected by any tests.) The other cause could be that normal current is not detected. In this case, neither incoming nor outgoing calls can be completed, and the Dial Tone test (#0) also fails. Check for other errors.

- e. **Error Type 2817 Aux Data 57393** is an inline error that has no specific test associated with it. CO released the trunk at least four minutes after the PBX dropped the call. This error code is log only and causes no other testing to occur. No alarm is generated. Check for other errors.
- f. **Error Type 3073 Aux Data 57376** is an inline error that has no specific test associated with it. No loop current on incoming call. The incoming destination has already answered and no loop current has been detected. If this is a hard fault, the Dial Tone test (#0) and every outgoing call should also fail. Check for other errors.
- g. **Error Type 3585 Aux Data 57424** is an inline error that has no specific test associated with it. No loop current on outgoing call. This error occurs on an attempt to seize a loop or ground-start trunk for an outgoing call. An error occurs if loop current is not detected or the caller hangs up before it is detected. Busyout the affected port, and run a Long test. If the Dial Tone test (#0) passes, ignore this error. Release the port.

Demand test descriptions and error codes

Investigate tests in the order presented. By clearing errors associated with the first test, errors generated from other tests may also be cleared. Click on the link to see the full description of the test, error codes, and recommended actions.

DLY-MTCE (Daily Maintenance)

MO Name in Log	Alarm Level	Initial Command to Run	Full Name of MO
DLY-MTCE	MINOR MAJOR WRN	NONE	Daily Maintenance

The DLY-MTCE MO performs daily translation audits and saves as part of the administered daily maintenance options on the **change system-parameters maintenance** form. If a translation save times out or fails, an error is logged against this MO.

If save fails	Then system raises
3 times in a row	MINOR Alarm
7 times in a row	MAJOR Alarm

If the audit fields are enabled on the **change system-parameters maintenance** form and the audit fails, a WARNING alarm is raised.

Error log entries

There is no repair action for these errors. Escalate the problem.

Table 89: DLY-MTCE Error Log Entries

Error Type	Description	Alarm Level
542	Translation save failure during scheduled maintenance	MIN MAJ
571	Translation save timeout during scheduled maintenance	MIN MAJ
572	Translation save failure during translation backup via the web (either scheduled or on-demand)	MIN MAJ
573	Translation audit has detected translation corruption during scheduled maintenance	WRN

Daily Maintenance Interference

[Table 90: Communication Manager SAT Command Actions](#) lists Communication Manager SAT administration command actions that, when active, interfere with daily maintenance. Customer administrators frequently use these commands for routine administration of the system.

Table 90: Communication Manager SAT Command Actions

Likely to Disrupt	Less Likely to Disrupt	
<code>add</code>	<code>backup</code>	<code>ping</code>
<code>change</code>	<code>busyout</code>	<code>recycle</code>
<code>duplicate</code>	<code>clear</code>	<code>release</code>
<code>remove</code>	<code>display</code>	<code>reset</code>
<code>set</code>	<code>enable</code>	<code>restore</code>
	<code>format</code>	<code>resume</code>
	<code>get</code>	<code>save</code>
	<code>list</code>	<code>status</code>
	<code>mark</code>	<code>test</code>
	<code>monitor</code>	<code>upgrade</code>
	<code>netstat</code>	

Other command actions can also interfere with daily maintenance when certain qualifiers are used in the commands, or under certain circumstances. For example, certain `test` commands, when used with the modifier *continuously*, could interfere with daily maintenance. However, such command actions are not typically used by customer administrators doing routine administration, and are less likely to disrupt daily maintenance routines than are the `add`, `change`, `duplicate`, `remove`, and `set` command actions.

Incomplete Command Time-Out

A command time-out feature exists on the `system-parameters maintenance`. The command time-out feature improves the operation of daily maintenance by allowing maintenance routines to run that might otherwise not run. It also helps to prevent the loss of translations that were not saved with `save translation`, and were also not saved because daily maintenance was prevented from running prior to the system reset. Highlights of the feature include:

- 1 Options for blank, 1, 2, 3, 4, 5, or 6 hours (the default is 2 hours)
- 1 The blank option indicates that the feature is not active

- 1 Only commands that block the running of daily maintenance (add, change, duplicate, remove, and set) are affected
- 1 All logins will time-out if any of these commands are active for the prescribed time (except for the “blank” option)
- 1 The feature applies to all logins, regardless of type (init, dadmin, craft, inads) or permissions granted to the specific login ID of an administration or maintenance user
- 1 The corresponding “time-out” entry is appended to the list history log

The **Command Time-out** field can be viewed by customer administrators. A craft, init, dadmin, or inads login is required to change the option for the field. [Figure 16: change system-parameters maintenance](#) shows the Maintenance-related System Parameters screen for Communication Manager.

DS1-BD (DS1 Interface Circuit Pack)

MO Name in Log	Alarm Level	Initial Command to Run	Full Name of MO
DS1-BD	MAJ MIN	<code>test board location 1</code>	DS1 Interface circuit pack
	WRN	<code>test board location</code>	

The DS1 Interface circuit pack provides an interface to an external DS1 facility and supports 24 DS0 channels carried on a 1.544-Mbps DS1 link. These DS0 channels can be administered as either trunks to other switches or lines to off-premises stations. The TN464C (or later-suffixed) Universal DS1 Interface also supports a 32-channel interface on a 2.048-Mbps link.

The functions and maintenance strategy for the TN464 circuit packs are covered under a separate MO, [UDS1-BD \(UDS1 Interface Circuit Pack\)](#).

The following table shows the capabilities of each DS1 circuit pack. The TN722 and TN722B are not supported on G3r V1 or later systems.

Circuit Pack Code	24-Channel	32-Channel	Tie Trunk Signaling	CO Trunk Signaling	DID Trunk Signaling	OPS Line Signaling
TN722/B	X		X			
TN767/B/C/D/E	X		X	X	X	X
TN464C/D/E/F/GP/HP	X	X	X	X	X	X (24-chl only)
TN2313	X	X	X	X	X	X

ISDN-PRI Trunk signaling (for example, Q.921, Q.931) requires a TN464D or higher suffix, TN2464, or TN2242 (tie trunk signaling only) and is handled by system software. The TN464, TN2464, and TN2242 are covered in [UDS1-BD \(UDS1 Interface Circuit Pack\)](#).

Each trunk and line have their own maintenance strategies. However, they all depend on the health of the DS1 Interface circuit pack. See the following sections for details:

- | [TIE-DS1 \(DS1 Tie Trunk\)](#)
- | [CO-DS1 \(DS1 CO Trunk\)](#)
- | [DID-DS1 \(Direct Inward Dial Trunk\)](#)
- | [OPS-LINE \(DS1 Off-Premises Station Line\)](#)
- | [ISDN-TRK \(DS1 ISDN Trunk\)](#)
- | [ISDN-PLK \(ISDN-PRI Signaling Link Port\)](#)

Signaling over the DS1 link must be synchronized between the transmitting and receiving ends to ensure error-free communication. See [SYNC \(Port Network Synchronization\)](#) for details.

Combined with a TN767E circuit pack, Avaya's 120A Integrated CSU module becomes an enhanced CSU. The 120A CSU, combined with new switch software and the functionality provided by a TN767E's hardware and firmware, provides functionality equivalent to an external stand-alone Avaya ESF T1 CSU. The 120A CSU connects to the TN767E circuit pack on the I/O connector panel on the back of the port carrier, and thus becomes an integrated part of the system. Throughout this document, the term 120A means a 120A (or later-suffixed) CSU.

The 120A CSU and the TN767E are for use in the United States of America with 1.544-Mbps DS1 service. For more information about the 120A CSU module see *Installing and Operating a 120A Channel Service Unit with Avaya Communication Manager*.

A TN767E and a 120A integrated CSU support on-demand loopback tests assisting fault detection between the:

- 1 TN767E circuit pack and the integrated CSU
- 1 Integrated CSU and an optional customer-premises loopback jack
- 1 Integrated CSU and a remote CSU.

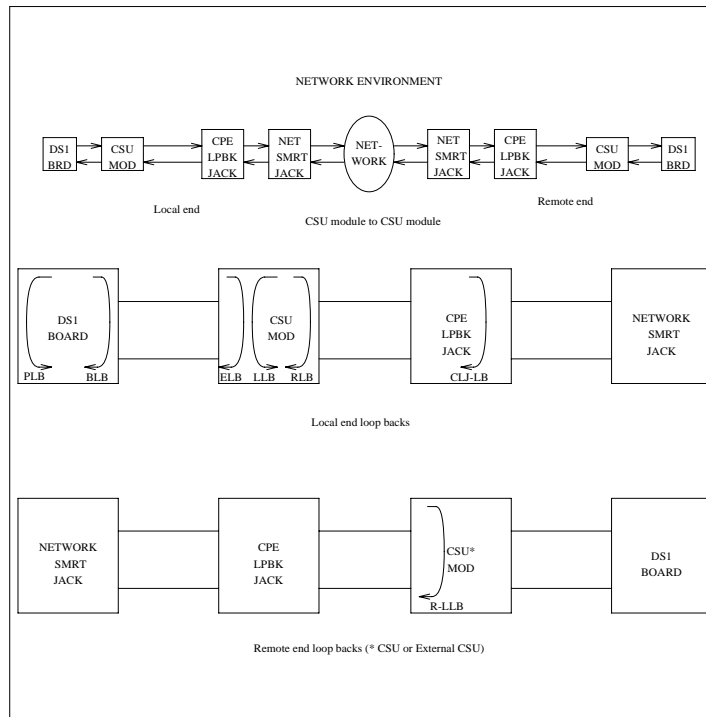

These loopback tests are explained in detail later in this DS1-BD section, but [Figure 17: High-Level Overview Of Loopback Points](#) gives a high-level overview of the loopback points.

The following list of acronym definitions are for [Figure 17: High-Level Overview Of Loopback Points](#):

- 1 PLB = Payload Loopback
- 1 BLB = Board Loopback
- 1 ELB = Equipment Loopback
- 1 LLB = Line Loopback
- 1 RLB = Repeater Loopback
- 1 CLJ = Loopback Jack Loopback
- 1 R-LLB = Remote Line Loopback
- 1 SMRT = Smart Jack
- 1 LPBK = Loopback

For more information about DS1 interfaces, refer to the *DEFINITY® Communications System Generic 2.2 and Generic 3 V2 DS1/CEPT1/ISDN-PRI Reference*.

3999 (y)	Any				
					4 of 4

Notes:

- a. **Error Type 0:** Run the short test sequence first. If every test passes, run the long test sequence. Refer to the test's description and follow the recommended procedures.
- b. **Error Type 1:** the circuit pack stopped functioning or is not completely administered. The alarm is logged approximately 15 minutes after the circuit pack has been removed or 11 minutes after the SAKI test (#53) fails.

To be completely administered, a DS1 circuit pack must:

- 1 Have an entry in the circuit plan field in **change circuit-packs**
- 1 Be administered using **add ds1 location**
- 1 Be physically inserted in the correct slot

If the circuit pack has an entry in the circuit plan and either of the other two conditions are *not* met, a MINOR alarm is logged. To resolve the error, either:

- 1 Make sure all conditions for administration are met and that a functioning DS1 circuit pack is inserted in the correct slot, or
- 1 Completely remove the DS1-BD from the system:
 1. Remove any administered DS1 trunks or access endpoints associated with the circuit pack from their trunk groups.

2. Execute `remove ds1 location` and `change circuit-packs UU`.

If all the administration conditions are met for this circuit pack and the red LED is still on, follow the instructions in LED alarms without alarm Log entry or with Error Type 1 in *LED Descriptions for Avaya Aura™ Communication Manager Hardware Components (03-602804)*.

- c. **Error Type 18:** the DS1 Interface circuit pack has been busied out by the `busyout board location` command. Use `busyout board location` to release the circuit pack.
- d. **Error Type 23:** the DS1-BD circuit pack is not completely administered. Ensure that the DS1-BD circuit pack has an entry in the circuit plan via `change circuit-packs`, is administered via `add ds1 location`, and is inserted into the correct port slot.
- e. **Error Type 125:** the circuit pack in the slot does not match the type administered to that position. Either replace the circuit pack with one of the type administered, or use `change circuit-packs` to re-administer the slot. This error may also indicate that the 24/32-channel selection on the DS1 administration screen does not match the configuration of the circuit pack.
- f. **Error Type 257:** transient communication problems between the switch and this circuit pack or media module. Enter `test board location` and refer to the repair procedures for the [Control Channel Looparound Test \(#52\)](#).
- g. **Error Type 513:** The DS1 Interface circuit pack has detected a transient hardware problem (for example, external RAM failure, internal RAM failure, internal ROM failure, or instruction set failure). This error disappears when no faults are detected for 30 minutes. The value in the `Aux Data` field indicates the type of hardware problem. However, if the **Aux Data** value is in the range of **4352 - 4358**, the circuit pack has reported a hardware failure. Escalate the problem.
- h. **Error Type 769:** The DS1 Interface circuit pack detected a transient hardware logic error (for example, program logic inconsistency). This error disappears when no faults are detected for 100 minutes. The value in `Aux Data` field indicates the type of hardware problem.
- i. **Error Type 1025:** CSU module or T1 sync splitter missing. The `Near-End CSU Type` field on the `add ds1` screen has been administered as `integrated`, but the 120A CSU or T1 sync splitter is not physically connected (or is improperly connected) to the DS1 board on the back of the port carrier.

If using the 120A CSU or T1 sync splitter, plug (or replug) the CSU or T1 sync splitter into the TN767E circuit pack's connector on the I/O connector panel on back of the carrier. Otherwise, change the `Near-End CSU Type` field using the `change ds1` screen to `other`.

If this error remains after plugging the 120A CSU or T1 sync splitter into the board's connector, there could be a problem with the I/O connector panel.

- j. **Error Type 1301:** CSU module/T1 sync splitter not expected. The 120A CSU or T1 sync splitter is physically connected to the TN767E board on the back of the port carrier, but the `Near-End CSU Type` field on the `add ds1` screen has not been administered as `integrated`.

If the 120A CSU or T1 sync splitter is to be used, use `change ds1` to change the `Near-End CSU Type` field to `integrated`. Otherwise, physically remove the 120A CSU or T1 sync splitter from the back of the port carrier.

- k. **Error Type 1302:** DS1 configuration error. Attempting to use a 120A CSU with a TN767E circuit pack that is configured for 32-channel (2.048-Mbps) operation. This CSU only works with a DS1 board configured for 24-channel (1.544-Mbps) operation in the United States of America.

- l. **Error Type 1303:** DS1 circuit pack suffix incorrect for CSU or T1 sync splitter. The `Near-End CSU Type` field on the `add ds1` screen has been administered as `integrated` but the DS1 circuit pack is not a TN767E (or higher-suffixed) DS1 board.

If the 120A CSU or T1 sync splitter is to be used, remove the circuit pack and replace it with a TN767E (or higher-suffixed) board. Otherwise, use `change ds1` to change the `Near-End CSU Type` field to `other`.

- m. **Error Type 1310:** BLB failure. This error occurs when the DS1 Board Loopback (BLB) demand test fails. Repeat the test using `busyout board location, test ds1-loop location ds1/csu-loopback-tests, release board location`. If the BLB test continues to fail, then the TN767E circuit pack needs to be replaced.
- n. **Error Type 1311:** ELB failure. This error occurs when the Integrated CSU (I-CSU) Module Equipment Loopback (ELB) test fails. This test is executed during I-CSU/T1 sync splitter power-up/reset (i.e., the TN767E board is physically inserted and the CSU module/T1 sync splitter is already installed) or when the CSU module/T1 sync splitter is plugged on to an already initialized DS1 board. The ELB test is also executed as part of `test ds1-loop location ds1/csu-loopback-tests`.

Attempt to clear the alarm with `busyout board location, test ds1-loop location ds1/csu-loopback-tests, and release board location`. If the ELB test continues to fail, then either the TN767E board, the CSU module, the T1 sync splitter, or the I/O cable between the backplane and the CSU module/T1 sync splitter (or any combination thereof) has failed. Escalate this problem.

- o. **Error Type 1312:** RLB failure. This error occurs when the Integrated CSU (I-CSU) Module Repeater Loopback (RLB) test fails. This test is executed during I-CSU/T1 sync splitter power-up/reset (i.e., the TN767E board is physically inserted and the CSU module/T1 sync splitter is already installed) or when the CSU module/T1 sync splitter is plugged on to an already initialized DS1 board. The RLB test is also executed as part of the command `test ds1-loop location ds1/csu-loopback-tests`.

Attempt to clear the alarm with `busyout board location, test ds1-loop location ds1/csu-loopback-tests, and release board location`. If the RLB test continues to fail, then the CSU module/T1 sync splitter needs to be replaced.

- p. **Error Type 1313:** CPE loopback jack deactivation error. This error occurs when the TN767E circuit pack could not deactivate a CPE loopback jack loopback.

Attempt to clear the alarm with `busyout board location, test ds1-loop location end-loopback/span-test`, and `release board location`. If the attempt to deactivate the CPE loopback jack loopback continues to fail, other steps must be taken to deactivate the loopback.

- q. **Error Type 1314:** Far CSU Loopback deactivation error. This error occurs when the TN767E circuit pack could not deactivate a far-end CSU loopback on power-up/reset or upon software request.

Attempt to clear the alarm with `busyout board location, test ds1-loop location end-loopback/span-test`, `release board location`. If the attempt to deactivate the Far CSU loopback continues to fail, then escalate the problem.

- r. **Error Type 1538:** The hyperactive circuit pack is out-of-service and may exhibit one or more of the following symptoms:

- 1 The common circuit pack-level tests, such as Test #51 and Test #220, are aborting with Error Code 2000.
- 1 The tests run on the ports of this circuit pack are returning NO BOARD.
- 1 A `busyout/release` of the circuit pack has no affect on test results.
- 1 `List configuration` shows that the circuit pack and ports are properly installed.

The circuit pack is isolated from the system and all trunks of this circuit pack are placed into the out-of-service state. The system will try to restore the circuit pack within 15 minutes. When no faults are detected for 15 minutes, the DS1 Interface circuit pack is restored to normal operation. All trunks of the DS1 Interface circuit pack are then returned to the in-service state. If the error recurs after 15 minutes, then escalate this problem.

- s. **Error Type 3160:** this board is receiving slips. The AUX Data displays the last Slip count that was reported.
- t. **Error Type 3329 - 3345:** this board is receiving misframes. The AUX Data displays the last misframe count that was reported.
- u. **Error Type 3840:** ignore. This error is not service-affecting.
- v. **Error Type 3900:** gives status information about a CPE Loopback Jack test. The value in the `Aux Data` field indicates the status of the loopback test:
Aux Data 1: Test is currently running.
Aux Data 2: Test failed because loopback could not be activated.
Aux Data 3: Test failed because test pattern could not be detected.
Aux Data 4: Test has been deactivated.
- w. **Error Type 3901:** gives status information about a Far CSU Loopback test. The value in the `Aux Data` field indicates the status of the loopback test.
Aux Data 1: Test is currently running.
Aux Data 2: Test failed because loopback could not be activated.

Aux Data 3: Test failed because test pattern could not be detected.

Aux Data 4: Test has been deactivated.

- x. **Error 3902:** gives status information about a One-Way Span test. The value in the `Aux Data` field indicates the status of the span test:

Aux Data 1: Test is currently running.

Aux Data 2: Test failed because loopback could not be activated.

Aux Data 3: Test pattern was not received from the far end.

Aux Data 4: Test has been deactivated.

- y. **Error Type 3999:** the circuit pack sent a large number of control-channel messages to the switch within a short period of time. If Error Type #1538 is also present, then the circuit pack was taken out-of-service due to hyperactivity. If Error Type #1538 is absent, then the circuit pack has not been taken out-of-service, but it has generated 50% of the messages necessary to be considered hyperactive. This may be completely normal during heavy traffic periods. However, if this Error Type is logged when the circuit pack is being lightly used, it may indicate a problem with the circuit pack or the equipment attached to it.

Demand test descriptions and error codes

Investigate tests in the order presented. By clearing errors associated with the first test, errors generated from other tests may also be cleared. Click on the link to see the full description of the test, error codes, and recommended actions.

DS1-FAC (DS1 Facility)

S8700-series Fiber-PNC

MO Name in Log	Alarm Level	Initial Command to Run	Full Name of MO
DS1-FAC	MAJ MIN WRN	<code>test board location</code>	DS1 Facility

The DS1-FAC is a part of the DS1 Converter (DS1C-BD) complex. The DS1C-BD complex consists of two TN574 DS1C-BD circuit packs or two TN1654 DS1C-BD circuit packs connected by one to four DS1 facilities. The MO name for the DS1 converter circuit pack is DS1C-BD, and the MO name for the connected DS1 facilities is DS1-FAC.

The TN1654 DS1 Converter circuit pack is a redesign of the TN574 DS1 Converter board. The TN1654 provides functionality equivalent to the TN574, and adds a 32-channel E1 interface for international support as well as circuit-switched wideband connections (NxDS0).

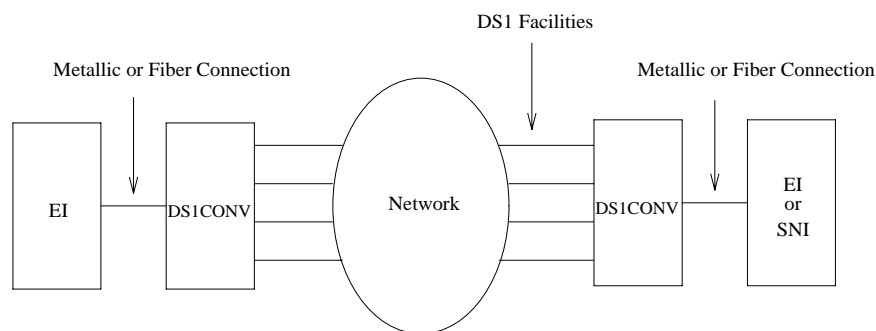

The TN1654 DS1 converter circuit pack is not compatible with the TN574 DS1 converter board or the Y-cable used to interface to the TN574 DS1 converter. A TN573B (or higher-suffixed) SNI board must be used when connecting to the TN1654 DS1 converter board. See DS1C-BD for information about both DS1 converter circuit packs.

The DS1 converter complex is a part of the port-network connectivity (PNC). The DS1 converter complex is used to extend the range of the 32-Mbps fiber links that connect PNs to the Center Stage Switch, allowing PNs to be located at remote sites.

The DS1 converter circuit pack contains on-board firmware that detects DS1 facility alarms and errors, provides status for maintenance software, and runs either background or on-demand tests.

DS1 converter circuit packs are connected to the Expansion Interface (EI) circuit packs (TN570) and the Switch Node Interface (SNI) circuit packs (TN573) as shown in [Figure 18: DS1 Converter Complex and the DS1 Facilities](#).

Figure 18: DS1 Converter Complex and the DS1 Facilities

The DS1 converter complex can replace fiber links between two EIs and fiber links between an PN's EI and an SNI. Fiber links between two SNIs and fiber links between the and the Center Stage Switch (CSS) can be replaced by a DS1 converter complex.

On the TN574 DS1 converter circuit pack, one of the four DS1 facilities is used as the primary facility (or packet facility), and it is the only facility that can carry packet traffic besides providing circuit connections. The primary facility has 22 channels available for circuit and packet connections. Other facilities each have 24 channels available for circuit connections. On the TN574 primary facility, channels 1 and 24 are not available for packet or for circuit connections. Channel 1 is used for excess packets traffic to prevent packet overflow that might result from zero code substitutions. Channel 24 is the DS1 control channel that carries control link data between the two DS1 converter circuit packs.

The primary facility on the TN1654 DS1 converter circuit pack is restricted to facility A or facility B. The TN1654 provides fixed packet bandwidth of 192 kbps while the TN574 provides packet bandwidth of up to 1408 kbps with a dynamic allocation mechanism that could change packet/circuit use of individual channels. The first three 64-kbps channels on the primary facility of the TN1654 are reserved as the packet channels. The DS1 control channel will be Channel 24 in T1 mode and Channel 31 in E1 mode. In T1 format the TN1654 provides 24 circuit channels for use on non-primary facilities and 20 circuit channels on the primary facility. E1 format provides 31 circuit channels for use on non-primary facilities and 27 circuit channels on the primary facility.

When there are alarms on the packet facility, DS1 converter circuit pack firmware changes the mapping of the DS1 channels to move the packet traffic to another facility. On TN574 DS1 converter boards, the packet traffic will be moved to another "Digital Data Compatible" facility (as indicated on the fiber link administration screen). On TN1654 DS1 converter boards, the packet traffic will be moved to either facility A or B if available. This mapping is done to keep the packet service operational at all times as the system control links are carried on these packet connections. When packet traffic is moved to another facility, circuit connections on the new facility are torn down and circuit connections on the old (faulty) facility are re-mapped to the new packet facility.

After firmware initialization, facility A, the first facility, is chosen as the default primary facility for both DS1 converter boards.

The TN574 DS1 converter has seven LEDs that provide an indication of the state of the DS1 converter circuit pack and the DS1 facilities. There is a yellow, a green, and a red LED under software and/or firmware control. There are four Green LEDs under hardware control that indicate, for each DS1 facility, whether a receive signal is present for the DS1 facility. From top to bottom these green LEDs correspond to DS1 facilities A, B, C, and D respectively. If one of the four green LED is on, it indicates a signal is present, but it does not imply that the signal is using the correct framing format (ESF or D4) or line coding (ZCS or B8ZS). See section DS1C-BD for the description of the red, the green, and the amber LEDs on the DS1 converter circuit pack.

The TN1654 DS1 converter board has eleven LEDs on its faceplate. The top three system standard LEDs (yellow, green and red) are used to provide an indication of the state of the DS1 converter board. The bottom four LEDs on the TN1654 board are labeled SPAN LEDs. These LEDs are under firmware control. If the facility is not administered, then the LED is not lit. The LED is lit amber if the facility is running alarm free. If the facility is detecting either a red alarm (loss-of-signal or loss-of-frame), a yellow alarm (remote frame alarm) or a blue alarm (AIS signal), the LED is lit red.

The TN1654 DS1 converter circuit pack supports the Wideband Switching feature. The TN574 DS1 converter does not.

DS1 Facility Busyout

Busy out the MO to gracefully disconnect service. Busyout puts the object out-of-service until the repair procedures are completed.

Use `busyout ds1-facility` to busy out DS1 facilities. When an attempt is made to busyout the packet facility (or primary facility), the system prints a warning message indicating that the *override* option must be used to busyout the packet facility. Busying out the packet facility moves the packet traffic to another facility, and disconnects circuit connections on that new facility.

The system does not allow the last packet DS1 facility to be busied out. In this case, busy out the DS1 converter circuit pack instead.

When the `busyout ds1-facility` command is executed, software communicates with both DS1 converter circuit packs in the DS1 converter complex. If the board at which the facility is being busied out is not accessible, the abort code 2100 is returned. If the board at the other end of the DS1 converter complex is not accessible, the abort code 105 is returned.

DS1 Facility Administration

DS1 facility administration is a part of the fiber link administration. DS1 options are set on the Fiber Link Administration screen. For critical-reliability systems, the Fiber Link Administration screen contains the DS1 facility options for the B side of the PNC.

DS1 facility administration is explained in the following sections. These descriptions do not provide complete coverage of fiber link administration.

Replacing a DS1 Facility

Disconnecting a DS1 facility is service disrupting except on critical-reliability systems since they have PNC duplication.

For a standard-, duplex-, or high-reliability system (no PNC duplication):

This procedure is destructive.

1. Use **busyout ds1-facility** to busy out the DS1 facility.
2. Replace the DS1 facility.
3. Use **release ds1-facility** to release the DS1 facility.

For a critical-reliability system (PNC duplication):

This procedure is nondestructive.

1. If the DS1 facility to be replaced is on the active PNC (its amber LED is on solid), use **reset pnc interchange** to do a PNC demand interchange. Use **status pnc** to determine the active PNC.
2. When the DS1 facility to be replaced is on the standby PNC (if the DS1 facility was originally on the standby PNC or after the PNC interchange has finished), use **busyout ds1-facility** to busyout the DS1 facility.
3. Replace the DS1 facility.
4. Use **release ds1-facility** to release the DS1 facility.

Installing a DS1 Facility

To install a DS1 facility:

1. Connect the facility.
2. Use **list fiber-link** to check the fiber link number.
3. Use **change fiber-link** to administer the DS1 facility via the command. Set the `Facility Installed` field to **y** for the facility that is being installed.
4. Use **busyout board** to busyout the DS1 converter circuit pack.
5. Use **test board location long** to run the [DS1 Facilities Connectivity Test \(#790\)](#), to ensure that the facilities are connected correctly.
6. Use **release board** to release the DS1 converter circuit pack.

Removing a DS1 Facility

Removing a DS1 facility is service disrupting in any system configuration, because the DS1 facility administration is similar on both sides of the PNC on critical-reliability systems.

This procedure is destructive.

1. Use **busyout ds1-facility** to busyout the DS1 facility.
2. Use **list fiber-link** to check the fiber link number.
3. Use **change fiber-link** to administer the DS1 facility. Set the `Facility Installed` field to **n** for the facility that is being removed.
4. Disconnect the DS1 facility (or facilities in a critical-reliability system configuration).

DS1 Interface Options

Use fiber link administration to set the following DS1 Interface options. Use `list fiber-link` to check the number of the fiber link. Execute `change fiber-link` and set the following fields:

Table 92: DS1 Interface Options administration 1 of 3

Field	Description
Facility Installed	<p>y when the facility is installed.</p> <p>For TN574 DS1 converter boards, facility A must be installed first. Install Facilities B, C and D in any order on any of the four facilities.</p> <p>For TN1654 DS1 converter boards, facility A must be installed first, then B, then C or D. This is required because the primary facility can only reside on facilities A or B.</p>
Passes Far-End Clock	<p>y when the DS1 facility is used as a clock reference for the receive fiber signal.</p> <p>Appears on the Fiber-Link screen for TN574 DS1 converter circuit packs.</p> <p>On the TN1654 DS1 converter board, none of the facilities can be used as a clock reference for the receive fiber signal, and administration of this field is not applicable.</p> <p>DS1 facilities cot be used as system synchronization sources.</p>
Digital Data Compatible	<p>y when the DS1 facility is digital data compatible and suitable for carrying packet traffic.</p> <p>Appears on the Fiber-link screen for TN574 DS1 converter circuit packs. The TN574 circuit pack allows any of the four facilities to be used as the primary facility that carries the packet traffic.</p> <p>The TN1654 DS1 converter board allows packet traffic only on facilities A and B, and administration of this field is not applicable.</p>
Bit Rate	<p>Select domestic T1 operation or international E1 operation for all facilities in the TN1654 DS1 converter complex:</p> <ul style="list-style-type: none"> 1.544 Mbps for T1 operation 2.048 Mbps for E1 operation <p>Appears on the fiber-link screen only for TN1654 DS1 converter circuit packs.</p> <p>The TN1654 DS1 converter circuit pack is also field configurable for T1 or E1 operation. All four DS1 facilities are configured to either T1 or E1 as a group via an option switch located on the component side of the circuit pack. An error is logged and an alarm is raised if there is a T1/E1 inconsistency between the administered bit rate and the board option switch setting.</p>
1 of 3	

Table 92: DS1 Interface Options administration 2 of 3

Field	Description
Idle Code	<p>Set the idle code for all facilities on the TN1654 DS1 converter board. This field can accept any combination of ones (1) and zeros (0) with the exception that the second left-most digit must be set to one (1) at all times.</p> <p>Appears on the fiber-link screen for TN1654 DS1 converter circuit packs</p>
CRC	<p>This field determines if CRC is enabled for every facility on a TN1654 circuit pack. The field is <i>y</i> if a cyclic redundancy check (CRC) is to be performed on transmissions that the board receives.</p> <p>CRC only applies to E1 operation and appears on the Fiber-link screen only for TN1654 DS1 converter circuit packs with a bit rate of 2.048 Mbps.</p>
DS1 Converter-1 and DS1 Converter-2 Line Compensation	<p>The DS1 facility line signal is pre-equalized at the transmitter on the DS1 converter circuit pack so that DS1 line pulses have correct amplitude and shape when they reach the Network Interface (see Figure 19: DS1 Facility Connections). The amount of equalization necessary is determined by the distance to the Network Interface, and also by the type of wiring used to connect to the Network Interface. If the equalization is not set to the correct value, potentially high error rates (errored seconds) will be observed on the DS1 facility. Table 93: DS1 Facility Line Signal Equalization Values explains how equalization values are determined.</p> <p>Line compensation is applicable only to T1 operation, thus these fields will not appear on the fiber-link screen if the TN1654 DS1 converter is administered for a bit rate of 2.048 Mbps.</p>
Line Coding	<p>Administer the line coding for the DS1 facility. For the TN574 board and the TN1654 board in T1 mode, the field may be set to <i>ami-zcs</i> or <i>b8zs</i>. If the TN1654 board is set for E1 operation, the line coding may be set to either <i>ami-basic</i> or <i>hdb3</i>. The line coding must be the same at each end of the DS1 converter complex.</p>
2 of 3	

Table 92: DS1 Interface Options administration 3 of 3

Field	Description
Framing Mode	<p><i>esf</i> or <i>d4</i> for the DS1 facility. The same framing mode must be used at each end of the DS1 converter complex.</p> <p>For TN574 DS1 converter boards, this is administrable.</p> <p>For TN1654 DS1 converter boards, this field is display only. The TN1654 has option switches located on the component side of the circuit pack. If T1 operation is selected via the first switch, four additional switches are used to select the framing mode for each facility. Each facility can be set to either D4 or ESF framing. The <code>Framing Mode</code> field will display what the switch is set to for the DS1 facility.</p> <p>Framing Mode is applicable only to T1 operation. This field does not appear on the fiber-link screen if the TN1654 DS1 converter is administered for a bit rate of 2.048 Mbps.</p>
Line Termination	<p>Display only, shows the line termination for the DS1 facility on the TN1654 DS1 Converter circuit pack.</p> <p>The TN1654 has option switches located on the component side of the circuit pack. If E1 operation is selected via the first switch, four additional switches are used to select the line termination for each facility. Each facility can be set to either CEPT 75 ohm coaxial or 120 ohm CEPT twisted pair. This line termination field will display what the switch is set to for the DS1 facility.</p> <p>Line Termination is applicable only to E1 operation. This field does not appear on the fiber-link screen if the TN1654 DS1 converter is administered for a bit rate of 1.544 Mbps</p>
Facility Circuit ID	Specify a unique alpha-numeric name for each DS1 facility. This field appears for each facility when Facility Installed is <i>y</i> .

DS1 Converter Performance Measurements Report

The DS1 Converter Performance Measurements provide link performance measurements for the DS1 facilities.

When no facility alarms exist on the DS1 facility, events that indicate a degradation in the performance of the DS1 facility are monitored and recorded. These events will generate alarms when performance of the DS1 facility has degraded below acceptable levels. These measurements include errored seconds, bursty seconds, severely errored seconds, and failed seconds.

There are two DS1 Converter Performance Measurements Sub-reports:

- 1 The DS1 Converter Performance Measurements Summary Report provides information about the worst 15-minute interval of data, the total for 24 hours of data and the current 15-minute counter for each of the previously mentioned counters.
- 1 The DS1 Converter Performance Measurements Detailed Report displays a detailed log for the last 96 15-minute intervals for each of the previously mentioned counters.

Access the DS1 Converter Performance Measurements Summary Report with `list measurements ds1-facility summary location [print | schedule]`. Access a more detailed version of the report with `list measurements ds1-facility log location f [print | schedule]`.

You can reset every hardware- and software-measurement counter for a given facility with `clear measurements ds1-facility location f`. The *Counted Since* time is also reset and the *Number of Valid Intervals* count is set to zero.

The reports are printed on the screen or, by using the `print` option, on a printer attached to the terminal.

Clearing Firmware Errors

DS1 converter error reports are generated by firmware autonomously. DS1 converter error reports are not associated with demand tests. The `test board clear` command does not affect the error status known by the DS1 converter firmware. To clear every on-board firmware-detected error unconditionally, use `clear firmware-counters`.

Error log entries and recommended actions

Table 94: DS1-FAC Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Recommended Action
0 (a)	0	Any	Any	Any	<code>test dsl-facility location</code>
1 (b)		Failure Audit #949	MAJ	ON	<code>test board location</code>
18 (c)	0	<code>busyout dsl-facility location</code>	WRN	OFF	<code>release dsl-facility location</code>
257 (d)		Failure Audit #949	MIN	ON	<code>test board location</code>
513 (e)	1	Failure Audit #949	MIN	OFF	<code>test board location</code>
513 (e)	2	Failure Audit #949	MIN	OFF	<code>test board location</code>
856 (f)		DS1 Facility Query for Slips/Misframes #972	MIN	OFF	none
1025 (g)		Failure Audit #949	MAJ ¹	OFF	<code>test board location</code>
1281 (h)	None	Failure Audit #949	MAJ ¹	OFF	<code>test board location</code>
1281 (h)	1	Failure Audit #949	MAJ ¹	OFF	<code>test board location</code>
1281 (h)	2	Failure Audit #949	MAJ ¹	OFF	<code>test board location</code>
1537 (i)		Failure Audit #949	MAJ ¹	OFF	<code>test board location</code>
1793 (j)		Failure Audit #949	MAJ ¹	OFF	<code>test board location</code>
2065 (k)		DS1 Facility Query for Slips/Misframes #972	MIN	OFF	none
2305 (l)		Failure Audit #949	MAJ	OFF	<code>test board location</code>
2561 (m)		Failure Audit #949	MIN ¹	OFF	<code>test board location</code>

1. These failures are logged as a WRN alarm when the error is first reported. The alarm severity is raised to a MAJOR in 15 minutes if the problem persists.

Notes:

When problems persist, use `reset board` to reset the DS1 converter circuit pack. This may temporarily resolve the error condition and restore service until further assistance is provided.

- a. **Error Type 0:** Run the short test sequence first. If every test passes, run the long test sequence. Refer to each test's description, and follow its recommended procedures.
- b. **Error Type 1:** A major failure occurred on the DS1 interface hardware on the DS1 converter circuit pack associated with this DS1 facility. Replace the DS1 converter circuit pack.
- c. **Error Type 18:** the DS1 facility has been busied out via the `busyout ds1-facility` command. To resolve this error, release the DS1 facility via `release ds1-facility`.
- d. **Error Type 257:** A minor failure occurred on the DS1 interface hardware on the DS1 converter circuit pack associated with this DS1 facility. Replace the DS1 converter circuit pack.
- e. **Error Type 513:** DS1 converter circuit packs in this DS1 converter complex do not match in their framing formats or line coding formats.

Aux Data 1 indicates that the framing formats (ESF or D4) do not match. For TN574 DS1 converter boards, the framing mode is administered on the fiber-link screen. The TN1654 DS1 converter has option switches located on the component side of the circuit pack. If T1 operation is selected via the first switch, four additional switches are used to select the framing mode for each facility. The `Framing Mode` field on the fiber-link screen is display-only for the TN1654 boards. It displays what the switch is set to for the DS1 facility. It can be administered.

Aux Data 2 indicates that the line coding formats do not match. Line Coding is an administrable value on the fiber-link screen. The line coding options are *ami-zcs* or *b8zs* for TN574 boards and TN1654 boards in T1 mode. For TN1654 boards in E1 mode, the line coding options are *ami-basic* or *hdb3*.

This error should clear in 15 minutes.

1. Verify that DS1 facility and the network is using the same line coding (*ami-zcs*, *b8zs*, *ami-basic*, *hdb3*) and framing mode (ESF, D4). Use `list fiber-link` and `display fiber-link` to check the values for this DS1 facility. Contact T1 Network Service to check the modes used by the network.

If the framing mode format differs on boards in a TN1654 DS1 converter complex, the DS1 converter board that has its option switch set incorrectly will have to be physically removed from the system in order to set the facility framing mode switch properly.

2. If the problem persists, reset both DS1 converter circuit packs via the `reset board`.
 3. If the problem still persists, replace this DS1 converter circuit pack.
 4. If the problem still persists, replace the DS1 converter circuit pack at the other end of the DS1 converter complex.
- f. **Error Type 856:** More than 88 negative and/or positive slip errors occurred. This error clears when there are no slips for 1 hour.

1. Enter **display errors** and follow the associated repair procedures for any SYNC, TDM-CLK, and SNC-BD errors.
 2. Verify that the DS1 facility and the network are using the same Line Coding. For TN574 boards and TN1654 boards in T1 mode, also verify that the Framing Mode used is the same. Use **list fiber-link** and **display fiber-link** to check the values for this DS1 facility. Contact T1 Network Service to check the modes used by the network. See [Line Coding](#) and [Framing Mode](#) for details on how these options apply to the TN574 and TN1654 DS1 converter boards.
 3. For TN574 boards and TN1654 boards in T1 mode, check line equalization settings as described in [DS1 Converter-1 and DS1 Converter-2 Line Compensation](#)”
 4. Enter **display errors** and follow the associated repair procedures for any EXP-INTF, and SNI-BD errors for the Fiber Endpoints. Enter **display errors** and follow the associated repair procedures for any FIBER-LK errors for this fiber link.
 5. If the problem still persists, replace this DS1 converter circuit pack.
 6. If the problem still persists, replace the DS1 converter circuit pack at the other end of the DS1 converter complex.
- g. **Error Type 1025:** Loss of Frame Alignment (LFA) Alarm, the RED alarm. This alarm indicates that the DS1 interface associated with the DS1 facility got frame up on the received data.

For the following repair procedure, see to [Figure 19: DS1 Facility Connections](#) and the diagrams in the related test descriptions.

1. If the network is used instead of private T1 lines, check that the DS1 facility and the network are using the same line coding. For TN574 boards and TN1654 boards in T1 mode, also verify that the Framing Mode used is the same. For TN1654 boards, verify that the two boards in the DS1 converter complex are using the same bit rate. Use **Llist fiber-link** and **display fiber-link** to check the values for this DS1 facility. Contact T1 Network Service to verify the modes set for the network. See [Line Coding](#), [Framing Mode](#), and [Bit Rate](#) for details on how these options apply to the TN574 and TN1654 DS1 converter boards.
2. Run the [Near-End External Loopback Test \(#799\)](#) via **test ds1-facility location external-loopback** by setting up a loopback at CPE side of CSU towards DS1 converter circuit pack shown as loopback point **LB 1** in the test description diagram. If the test fails, replace connectors and the cables between CSU and the DS1 converter circuit pack.
3. If the test passes, run the [Near-End External Loopback Test \(#799\)](#) via **test ds1-facility location external-loopback** by setting up a loopback at DS1 facility side of CSU towards the DS1 converter circuit pack shown as loopback point **LB 2** in the test description diagram. If the test fails, replace the CSU.

4. If Test #799 passes, run the [Far-End Internal Loopback Test \(#797\)](#) via `test ds1-facility location long`. If Test #797 passes, go to step 6. If the test fails, run the [Near-End External Loopback Test \(#799\)](#) using `test ds1-facility location external-loopback` at the other end of the DS1 converter complex, and repeat steps 2 and 3 for the other endpoint.

If this is not a critical-reliability system and if there is only one DS1 facility, then Test #799 can only be executed at the end that is closer to the server relative to the DS1 converter circuit pack at the end of the DS1 converter complex. If the test cannot be executed for this reason, then replace the cables, connectors and the CSU at the other end of the DS1 converter complex.

5. If the problem could not be isolated by the near-end external loopback tests, then the fault should be between CSU A and CSU B. Contact T1 Network Service to resolve the problem(*).
6. If the problem still persists, check for excessive slips and synchronization problems. Enter `display errors` and follow the associated repair procedures for any SYNC, TDM-CLK, or SNC-BD errors. For TN574 boards and TN1654 boards in T1 mode, check line equalization settings as described in [DS1 Converter-1 and DS1 Converter-2 Line Compensation](#).
7. Enter `display errors` and follow the associated repair procedures for any EXP-INTF, and SNI-BD errors for the Fiber Endpoints. Enter `display errors` and follow the associated repair procedures for any FIBER-LK errors for this fiber link.
8. If the problem still persists, replace this DS1 converter circuit pack.
9. If the problem still persists, replace the DS1 converter circuit pack at the other end of the DS1 converter complex.

If D4 framing mode is used, an in-band alarm signal (RFA) will be transmitted that will corrupt the transmit data on this facility.

h. Error Type 1281:

Aux Data None: This entry in the DS1 Facility Error Log occurs only prior to Release V5. The DS1 converter circuit pack's neighbor (the DS1 converter circuit pack at the other end of the DS1 converter complex) is unable to frame up on the signal being sent to it by this DS1 converter circuit pack on this DS1 facility. The far-end facility will be in LFA state. To isolate faults for this case, follow the repair procedure for Error Type #1025 for the other end of the DS1 facility. Note that references to the near and far ends are reversed, for example, the neighbor is now the near end. If D4 framing is used, received data will be corrupted as well as transmitted data.

Aux Data 1: indicates that the facility is detecting a Remote Frame Alarm (RFA), also known as the YELLOW alarm, being sent by the remote DS1 endpoint. This Yellow alarm corresponds to the yellow F2 state documented in CCITT Recommendation I.431. If D4 framing is used, received data will be corrupted in addition to transmitted data.

Aux Data 2: indicates that the facility is detecting a yellow F5 state alarm. This error only applies to TN1654 DS1 converter boards in 32-channel E1 operation with CRC enabled via the fiber-link screen. The F5 fault state is defined as a fault in the user-network interface, specifically in the direction from the user (PBX) to the network. Refer to CCITT recommendation I.431.

The far-end facility will be in LFA state. To isolate faults for this case, follow the same repair procedure as in Error Type #1025 (loss of frame alignment) for the other end of the DS1 facility.

- i. **Error Type 1537:** Alarm Indication Signal (AIS), the BLUE alarm. This alarm indicates that the far end of the facility is out of service. This means that the other end of the DS1 facility is undergoing maintenance testing or has a LOS condition and the CSU is providing a Keep Alive signal. If the Keep Alive signal is not supplied by the CSU, a LOS condition will exist on the facility instead of the AIS. If a LOS condition exists on the facility, the green LED on the TN574 DS1 converter circuit pack that is associated with the facility will be off; if an AIS condition exists on the facility, the green LED that is associated with the facility that has the AIS will be on. For TN1654 DS1 converter boards, the LED associated with the facility will be lit red if either the LOS or AIS conditions exist.

To isolate faults for this case, follow the same repair procedure as in Error Type #1793 (loss of signal) for the other end of this DS1 facility.

An RFA alarm indication (YELLOW alarm) is transmitted in response to this BLUE alarm. If D4 framing is used, transmitted data is corrupted.

- j. **Error Type 1793:** Loss of Signal (LOS) alarm. This alarm indicates that no signal is present at the DS1 interface associated with the facility. On TN574 DS1 converter boards, the green LED that is associated with the facility will be off. For TN1654 DS1 converter boards, the LED that is associated with the facility will be lit red. If the LED behavior differs, replace the DS1 converter circuit pack.

Fault isolation for this problem may be different depending on the capabilities of the CSU device that is being used. Typically, CSUs provides an LED that is useful for fault isolation (see [Figure 20: Typical CSU Maintenance Capabilities](#)). This is the “16 Zeros” LED. This LED is momentarily lit when a string of 16 consecutive zeros is detected in the DS1 signal from the DS1 converter. Zeros on a DS1 link are represented by an absence of a pulse. Thus, an active 16 Zeros LED indicates a LOS alarm from the DS1 converter.

For the following repair procedure, see [Figure 19: DS1 Facility Connections](#) and the diagrams in the related test descriptions.

1. If the DS1 facility side LOS indication on CSU A is off (inactive), check for a problem between the DS1 converter A circuit pack and the CPE side of CSU A. Connectors, cables, and the CSU may need to be replaced.
2. If the DS1 facility side LOS indication on CSU A is on (active), check for a problem between the CSU A and the CSU B. Contact T1 Network Service to resolve the problem. DS1 facility may be a private line or it may be connected to the Network. Network Interface (NI) point is where the customer’s maintenance responsibility ends and the DS1 facility vendor’s maintenance responsibility begins. This point ideally is the T, R, T1, and R1 terminals on the rear of the CSU to which the wires of the DS1

facility vendor's DS1 facility is attached. If the NI does not occur at this point, then any cabling between the CSU terminals and the NI is also considered to be part of the CPE. This cable typically runs between the DS1 facility terminals of the CSU and a cross-connect field where the DS1 facility vendor has terminated the DS1 facility. Maintenance responsibility for this portion of the DS1 facility resides with the customer unless other arrangements are made.

3. If the CPE side LOS indication on CSU B is on (active), check for a problem between the CPE side of CSU B and the DS1 converter B circuit pack. Connectors, cables, and the CSU B may need to be replaced.
4. If the CSU A and the CSU B do not provide visual CPE side and DS1 facility side LOS indications, follow the repair procedure that is given for Error Type 1025 (loss of frame alignment). Apply the procedure first to the DS1 converter B side instead of the DS1 converter A where the error is reported (external loopback test is not expected to pass if we execute it at this end as long as we have the LOS indication).

Repair procedure for Error Type #1025 (loss of frame alignment) includes execution of the [Near-End External Loopback Test \(#799\)](#). If this is not a critical-reliability system and if there is only one DS1 facility, then Test #799 can only be executed at the end that is closer to the server relative to the DS1 converter circuit pack at the end of the DS1 converter complex. If the test cannot be executed for that reason, then still make the external loopback as if the test was going to be executed, but instead of executing the test, check the green LED at the face plate of the DS1 converter B that is associated with this DS1 facility. If the green LED is off, then replace the connectors, cables, and the CSU B.

5. If the problem still persists, replace the DS1 converter circuit pack at the other end of the DS1 converter complex.
6. If the problem still persists, replace this DS1 converter circuit pack.

If D4 framing is used, an in-band alarm signal (RFA) is transmitted that corrupts transmit data in response to this alarm.

- k. **Error Type 2065:** More than 17 misframe errors occurred. This error will clear when there are no misframes for 1 hour.
 1. Enter `display errors` and follow the associated repair procedures for any [SYNC \(Port Network Synchronization\)](#), [TDM-CLK \(TDM Bus Clock\)](#), or [SNC-BD \(Switch Node Clock Circuit Pack\)](#) errors.
 2. Verify that the DS1 facility and the network are using the same Line Coding. For TN574 boards and TN1654 boards in T1 mode, also verify that the Framing Mode used is the same. Use `list fiber-link` and `display fiber-link` to check the values for this DS1 facility. Contact T1 Network Service to check the modes used by the network. See [Line Coding](#) and [Framing Mode](#) for details on how these options apply to the TN574 and TN1654 DS1 converter boards.
 3. For TN574 boards and TN1654 boards in T1 mode, check line equalization settings as described in [DS1 Converter-1 and DS1 Converter-2 Line Compensation](#).

4. Enter **display errors** and follow the associated repair procedures for any EXP-INTF, and SNI-BD errors for the Fiber Endpoints. Enter **display errors** and follow the associated repair procedures for any FIBER-LK errors for this fiber link.
 5. If the problem still persists, replace this DS1 converter circuit pack.
 6. If the problem still persists, replace the DS1 converter circuit pack at the other end of the DS1 converter complex.
- I. Error Type 2305:** Facility Packet Channel Loopback Error. This error indicates that the DS1 converter primary facility that carries the packet time slots and DS1 control channel is looped to itself. This error applies only to facilities A and B on TN1654 DS1 converter boards. If both facilities A and B are being used and firmware detects a loopback condition an attempt will be made to switch the primary facility to the other facility. If the other facility is looped, down or not being used, the PN will be down until this loopback is removed.
1. Check the loopback LEDs on both CSU A and CSU B as shown in [Figure 19: DS1 Facility Connections](#) to see if a CSU is in a loopback mode. Also check to see if the CSUs have been manually hard-wired into a loopback mode. Remove detected loopbacks.
 2. If the CSUs are not in loopback mode, reset both DS1 converter boards via **reset board**.
- m. Error Type 2561:** Facility Jitter Alarm. This alarm indicates excessive receive jitter on the DS1 facility. This error only applies to TN1654 DS1 converter boards. The problem is external to the DS1 converter board. It could be caused by bad wiring, a bad device (CSU or repeater) or a bad signal coming in at the Network Interface.

Figure 19: DS1 Facility Connections

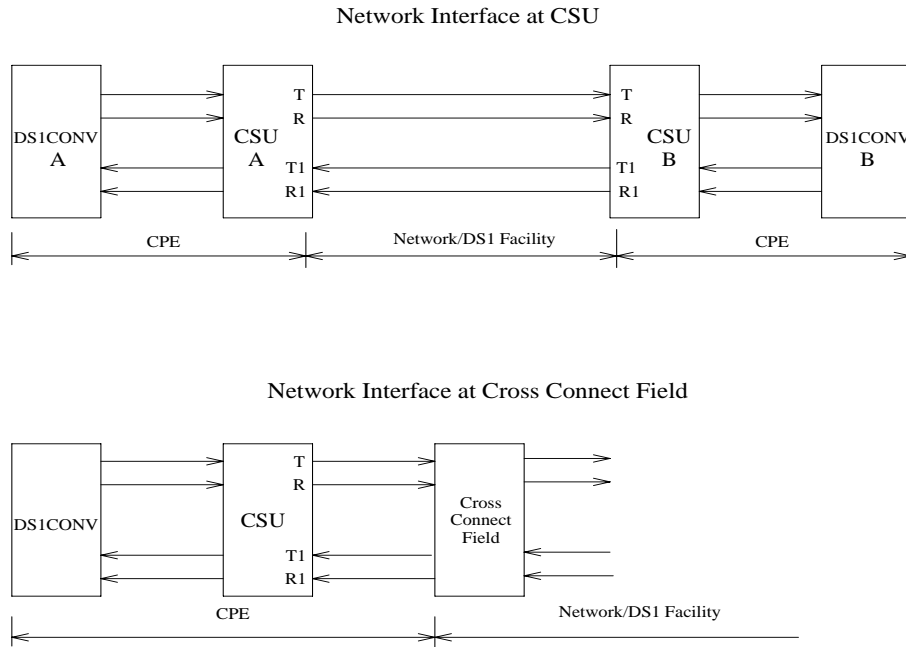

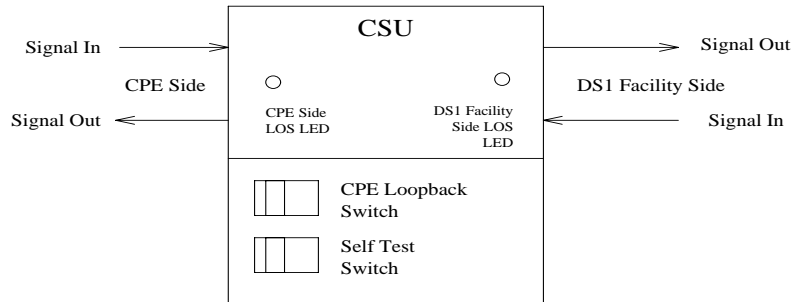

Figure 20: Typical CSU Maintenance Capabilities

Demand test descriptions and error codes

Investigate tests in the order presented. By clearing errors associated with the first test, errors generated from other tests may also be cleared. Click on the link to see the full description of the test, error codes, and recommended actions.

Order of Investigation	Short Test Sequence	Long Test Sequence	External Loopback	D/ND ¹
Failure Audit Test (#949)	X	X		ND
DS1 Interface Options Audit (#798)	X	X		ND
Far-End Internal Loopback Test (#797)		X		D
Near-End External Loopback Test (#799)			X	D

1. D = Destructive; ND = Nondestructive

DS1C-BD (DS1 Converter Circuit Pack)

S8700-series Fiber-PNC

MO Name in Log	Alarm Level	Initial Command to Run	Full Name of MO
DS1C-BD	MAJ MIN WRN	<code>test board location</code>	DS1 converter circuit pack

The DS1 converter complex is part of the port-network connectivity (PNC) consisting of two TN574 DS1 Converter or two TN1654 DS1 Converter circuit packs connected by one to four DS1 facilities. It is used to extend the range of the 32-Mbps fiber links that connect PNs to the Center Stage Switch, allowing PNs to be located at remote sites.

The TN1654 DS1 Converter Circuit pack is a redesign of the TN574 DS1 Converter board. The TN1654 provides functionality equivalent to the TN574 but also adds a 32-channel E1 interface for international support as well as circuit-switched wideband connections (NxDS0).

Every error condition reported by the firmware is associated with background tests that the firmware runs autonomously. Demand tests that are executed by the maintenance software do not cause any new error generation by the firmware. However, the [Failure Audit Test \(#949\)](#) affects auditing of the software error log by forcing the firmware to report the pending errors again.

Maintenance of the DS1 facilities themselves is covered under the “DS1-FAC” MO.

The DS1 converter complex can extend a fiber link between two EIs or between a PN EI and an SNI. Fiber links between two SNIs or between a PN and the Center Stage Switch (CSS) can be extended.

The TN1654 board is not compatible with the TN574 board. A DS1 converter complex may consist of two TN574 boards or two TN1654 boards, but a TN574 can be combined with a TN1654 in the same complex. A system with multiple DS1 converter-remoted PNs may contain DS1 converter complexes of both types, TN1654 board-pairs and TN574 board-pairs. Critical-reliability configurations with a pair of DS1 converter complexes serving an PN require identical board pairs and facilities. For example, a TN574 complex and a TN1654 complex may not be used together to serve the same PN in a critical-reliability configuration.

DS1 converter circuit packs connect to TN570 Expansion Interface (EI) circuit packs and TN573 Switch Node Interface (SNI) circuit packs via metallic cables as shown in [Figure 21: DS1 converter connection to EIs and SNIs](#). A fiber link cable can be used instead of the metallic cable if it is necessary to locate the DS1 converter far from the connected EI or SNI circuit pack, for example, in an adjacent cabinet.

The DS1 converter circuit pack can be placed in any regular slot in a PN carrier. However, the DS1 converter circuit pack can only be placed in slots 1 and 21 in a Switch Node (SN) carrier. The DS1 converter circuit pack is not connected to the TDM bus or the SN backplane. Communication to the circuit pack is done through the connected EI or the SNI circuit packs. Therefore, there is considerable interaction between the DS1 converters and the connected EIs and the SNIs. A special “Y” cable connects the DS1 converter circuit pack to the Fiber Endpoint and to the facilities.

Note:

The two DS1 converter boards, TN1654 and TN574, use unique “Y” cables that are incompatible with each other.

The TN573 SNI circuit pack is incompatible with the TN1654 board. A TN573B (or higher-suffixed) SNI board must be used when connecting to a TN1654 board. The TN573B SNI board is fully backward compatible with the TN573 board and can be connected to either TN1654 or TN574 boards.

Note:

A TN573B (or higher-suffixed) board must be used when connecting a SNI board to a TN1654 board. Error 125 will be logged and an on-board minor alarm will be generated against the SNI board if it is incompatible with the TN1654 circuit pack.

[Figure 22: DS1 converter Complex in Direct Connect PNC](#) and [Figure 23: DS1 Converter Complex in Duplicated PNC with 1 SN](#) show DS1 converter connections in a direct-connect PNC configuration and between the CSS and an PN in a critical-reliability system configuration (duplicated PNC).

Figure 21: DS1 converter connection to EIs and SNIs

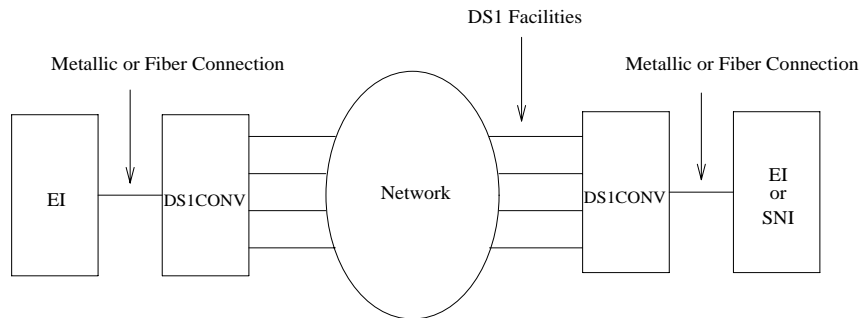

Figure 22: DS1 converter Complex in Direct Connect PNC

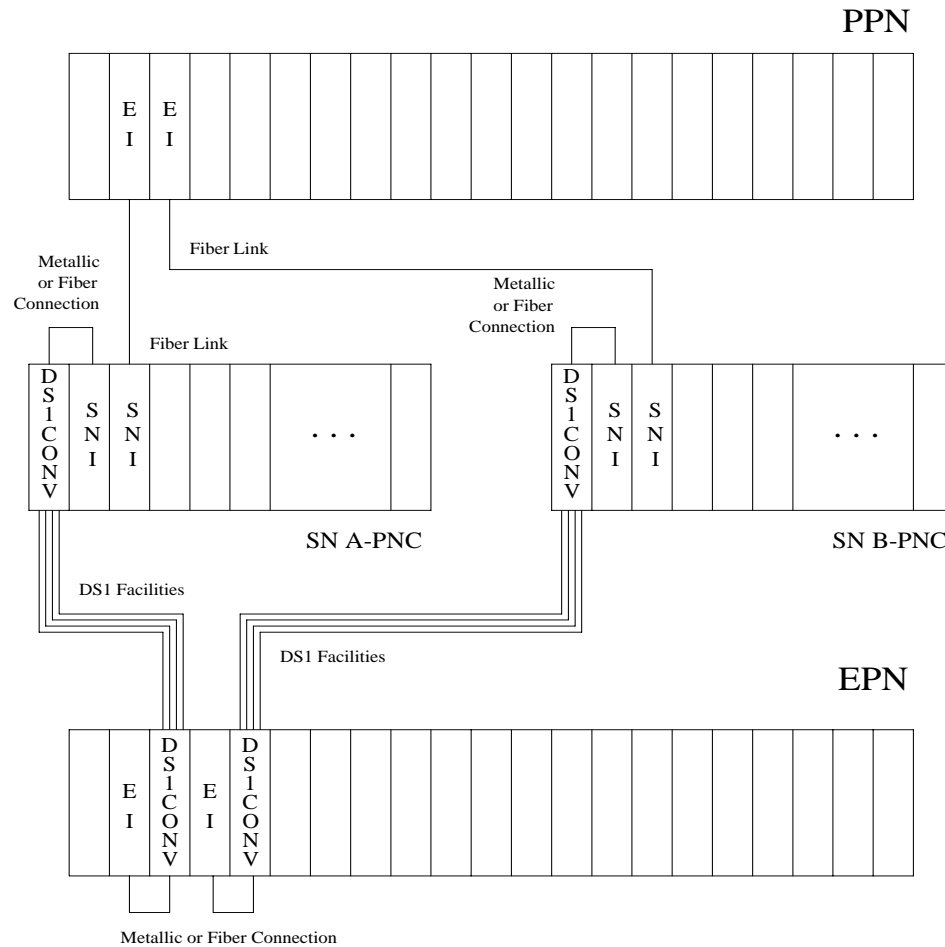

Figure 23: DS1 Converter Complex in Duplicated PNC with 1 SN

DS1 Converter Administration and Board Insertion

Board insertion is the detection of a circuit pack by the system. The DS1 converter circuit pack will not be inserted unless the circuit pack type, TN574 or TN1654, is entered into the associated field in circuit pack administration screen. The Fiber Endpoint (the EI or the SNI) must also be inserted and be operational for the DS1 converter circuit pack to function.

Fiber link administration must be completed before the DS1 converter maintenance can be operational. Fiber links are administered via `add fiber-link`. Fiber Endpoints, DS1 converter circuit pack locations and DS1 facility options are entered as a part of the fiber link administration.

To administer a standard-, duplex-, or high-reliability system (no PNC duplication):

1. Administer carriers via `add/change cabinet`.
2. Administer circuit packs via `change circuit-pack`.
3. Administer connectivity and the facility options of the DS1 converter complex via `add/change fiber-link`.

To administer a critical-reliability system (PNC duplication):

1. Enable PNC duplication feature using the `change system-parameter customer-option`.
2. Administer carriers via `add/change cabinet`.
3. Administer circuit packs via `change circuit-pack`.
4. Administer connectivity and the DS1 facility options of each DS1 converter complex via `add/change fiber-link`.
5. Turn on PNC duplication via `change system-parameter duplication`.

TN1654 Board Configuration Switch Settings

The TN1654 DS1 converter circuit pack is field configurable for T1 or E1 operation so that a single board serves worldwide application. All four DS1 facilities are configured to either T1 or E1 as a group via an option switch located on the component side of the circuit pack. If T1 operation is selected, four additional switches are used to select the framing mode for each facility. Each facility can be set to either D4 or ESF framing. If E1 operation is selected, the same four switches are used to select the E1 facility line termination impedance. The E1 line termination impedance for each facility can be set to either 120 Ω for twisted-pair or 75 Ω for coaxial wiring.

T1 or E1 operation must also be administered for the TN1654 DS1 converter board on the fiber-link screen via the `Bit Rate` field. An error will be logged and an alarm will be raised if there is a T1/E1 inconsistency between the administered bit rate and the board option switch setting.

The T1 facility framing mode and the E1 facility line termination impedance are defined by the option switch settings only. Administration of these values is not allowed. The fiber-link screen will display the selected option switch settings for each facility.

DS1 Converter LEDs

The TN574 board has seven LEDs on its faceplate. The TN1654 board has eleven LEDs on its faceplate. The top three system standard LEDs are used to provide an indication of the state of the DS1 converter board. These LEDs are under firmware control until the board has established a link to the server via the EI or SNI. Once the link is established, software controls the three LEDs. If the link breaks, the LEDs are again under firmware control.

The red and green LEDs have the traditional use where red means an alarm condition and green indicates that maintenance testing is in progress. The red and green LED is also turned on during circuit pack initialization by firmware. When the control link to the circuit pack is lost, firmware controls the red LED to indicate an alarm condition.

The amber LED indicates the state of the:

- 1 Physical fiber interface
- 1 Fiber channel (link to EI or SNI)
- 1 DS1 control channel (link to opposite DS1 converter board)
- 1 Server communications link

in the following order and descending order of priority. (The amber LED stays lit longer as the DS1 converter complex approaches full operation.)

1. If the fiber is out of frame or is in a loss-of-signal condition, the amber LED will flicker at a 5-Hz rate (on for 0.1 second, off for 0.1 second).
2. If the fiber channel is down (DS1 Converter circuit pack/fiber endpoint communications), the amber LED will flash at a 1-Hz rate (on for ½ second, off for ½ second).
3. If the DS1 control channel is down between the two DS1 converters in the DS1 converter complex, the amber LED will pulse at a 1/2-Hz rate (on for 1 second, off for 1 second).
4. If the server communications link is down, the amber LED will wink off every 2 seconds for 200 msec (2 seconds on, 0.2 second off).
5. If all is well with the Fiber Interface and every communications channel, the amber LED will remain on continuously in a standard-, duplex-, or high-reliability system. In a critical-reliability system (duplicated PNC):
 - An active DS1 converter circuit pack's amber LED remains on continuously.
 - A standby DS1 converter circuit pack's amber LED remains off.

The LED will then be under software control.

The bottom four green LEDs on the TN574 DS1 converter board are under hardware control. The four green LEDs indicate, for each DS1 converter facility, whether a receive signal is present for the DS1 facility.

The next four LEDs on the TN1654 DS1 converter board are labeled STATUS LEDs and are for future use. These LEDs will not be lit.

The bottom four LEDs on the TN1654 board are labeled SPAN LEDs. These LEDs are under firmware control. If the facility is not administered, then the LED is not lit. The LED is lit amber if the facility is running alarm free. If the facility is detecting either a red alarm (loss-of-signal or loss-of-frame), a yellow alarm (remote frame alarm) or a blue alarm (AIS signal) then the LED is lit red. The SPAN SELECT Switch on the TN1654 faceplate is for future use. Pushing the switch will have no effect on the board.

Clear Firmware-Counters Command

DS1 converter firmware generates error reports autonomously. This takes place independently of demand tests. The `test board location clear` command will not affect the error status reported by firmware. The `clear firmware-counters` command clears every on-board firmware-detected error unconditionally.

The `clear firmware-counters location` command sends a downlink message to the DS1 converter circuit packs, causing them to clear out their firmware error counters and failure databases. Once the firmware failure database is cleared, the [Failure Audit Test \(#949\)](#) will pass. If problems still exist, the firmware will increment its error counters and the failure audit test will begin failing again.

This command should not be used as a replacement for the repair procedures associated with the error log entries. This command may be useful if a problem has been fixed and off-board alarms associated with the problem are still active.

Downtime Required when Upgrading to TN1654 DS1 Converter Circuit Packs

Upgrading from TN574 DS1 converter circuit packs to TN1654 DS1 converter circuit packs will require down time for the affected PN.

The TN1654 DS1 Converter circuit pack is not compatible with the TN573 SNI circuit pack, the TN574 DS1 converter board, the Y-cable used to connect to the TN574 DS1 converter board or pre-G3V5 software. All DS1 converter boards and Y-cables must be upgraded. If the PN is remoted via a Center-Stage Switch, the connected SNI must also be upgraded. A TN573B (or higher-suffixed) SNI board must be used when connecting to a TN1654 DS1 converter board.

Use `remove fiber-link` to remove the fiber-link administration for the TN574 DS1 converter complex. Use `change circuit-pack` show that TN1654 boards are now being used. Then use `add fiber-link` to administer the TN1654 DS1 converter complex.

Replacing a DS1 Converter Circuit Pack with the Same Type DS1 Converter Circuit Pack — Unduplicated PNC

Do not power down a Switch Node carrier to replace a circuit pack.

Replacing a Switch Node Interface, Switch Node Clock, Expansion Interface or DS1 Converter circuit pack on an unduplicated system disrupts service. The service effect can range from outage of a single PN to outage of the entire system.

A DS1 Converter complex must consist of two TN574 boards or two TN1654 boards. A TN574 can be combined with a TN1654 in the same DS1 converter complex.

Steps	Comments
Enter <code>busyout board location</code> .	location represents the cabinet-carrier-slot address of the circuit pack to be replaced.
Replace the circuit pack with the same DS1 converter board type.	
Wait for the circuit pack to reset.	Red and green LEDs will light and then go out.
Enter <code>release board location</code>	CAUTION: <i>Do not busyout any Expansion Interface circuit packs after this point.</i>
Enter <code>test alarms long clear</code> for category <code>exp-intf</code> .	
Wait 5 minutes for SNI-BD, FIBER-LK, and DS1C-BD alarms to clear, or enter <code>clear firmware-counters a-pnc</code> .	

Replacing a DS1 Converter Circuit Pack with the Same Type DS1 Converter Circuit Pack—Duplicated PNC

On a system with duplicated PNC, synchronization may be provided over a combination of active and standby components. This condition is indicated by an OFF-BOARD WRN alarm against TDM-CLK with Error Type #2305. Repairs to standby PNC in this state may disrupt service. Otherwise, if the active PNC is functional, replacement of a standby component will not disrupt service.

Steps	Comments
Enter <code>status pnc</code> .	Verify that the component to be replaced is on the standby PNC.
Enter <code>busyout pnc</code> .	
Enter <code>busyout board location</code> .	location represents the cabinet-carrier-slot address of the circuit pack to be replaced.
Replace the circuit pack with the same DS1 converter board type.	
Enter <code>release board location</code> .	<i>CAUTION: Do not busyout any Expansion Interface circuit pack after this point.</i>
Enter <code>test alarms long clear</code> for category <code>exp-intf</code> .	
Wait 5 minutes for SNI-BD, SNI-PEER, FIBER-LK, and DS1C-BD alarms to clear, or enter <code>clear firmware-counters <a-pnc or b-pnc></code> .	Use the letter designation of the pnc that holds the replaced component (the standby pnc).
Enter <code>status pnc</code> .	If either PNC's state of health is not "functional", consult the PNC-DUP section of the Maintenance Manual.
Enter <code>release pnc</code> .	

Do not power down a Switch Node carrier to replace a circuit pack.

Replacing a Switch Node Interface, Switch Node Clock, Expansion Interface or DS1 Converter circuit pack on an unduplicated system disrupts service. The service effect can range from outage of a single PN to outage of the entire system.

A DS1 Converter complex must consist of two TN574 boards or two TN1654 boards. A TN574 can be combined with a TN1654 in the same DS1 converter complex.

The two DS1 converter boards, TN1654 and TN574, use unique “Y” cables that are incompatible with each other.

A TN573B (or higher-suffixed) board must be used when connecting a SNI board to a TN1654 DS1 Converter board.

Steps	Comments
Enter <code>list fiber-link</code>	Determine the fiber-link number associated with the two TN574 circuit packs to be upgraded.
Enter <code>busyout fiber-link fiber#</code>	Fiber# represents the fiber-link number associated with the TN574 DS1 converter complex that is being upgraded to a TN1654 DS1 converter complex.
Enter <code>remove fiber-link fiber#</code>	
Remove the TN574 DS1 converter circuit packs from the system.	
Replace the TN574 Y-cables with TN1654 Y-cables.	
Replace the removed TN574 DS1 converter circuit packs with TN1654 DS1 converter circuit packs. Prior to installing the TN1654 boards, review the prior section, <i>TN1654 Board Configuration Switch Settings</i> .	
If a TN1654 DS1 converter board is connected to an SNI board, upgrade the SNI to a TN573B or greater.	
Wait for the circuit packs to reset	Red and green LEDs will light and then go out.
1 of 2	

Steps	Comments
Enter <code>change circuit-packs cabinet #</code> . Update the screen to show that TN1654 boards are now being used instead of TN574 boards. Also update the connected SNI, if applicable, to suffix B.	Cabinet # represents the cabinet associated with a DS1 converter board. The <i>change circuit-packs</i> screen needs to be updated for both DS1 converter boards. Also, if needed, re-add translations for connected EI boards.
Enter <code>add fiber-link fiber#</code> to re-add the fiber-link using TN1654 DS1 converter circuit packs.	Fiber# represents the fiber-link number associated with the TN574 DS1 converter complex that is being upgraded to a TN1654 DS1 converter complex
Enter <code>test alarms long clear</code> for category <code>exp-intf</code> .	
Wait 5 minutes for SNI-BD, FIBER-LK AND DS1C-BD alarms to clear, or enter <code>clear firmware-counters a-pnc</code>	
2 of 2	

Upgrading TN574 DS1 Converter Circuit Packs in a Fiber-Link to TN1654s — Duplicated PNC

Do not power down a Switch Node carrier to replace a circuit pack.

In duplicated PNC configurations, one DS1 converter complex in the fiber-link serves as the active and the second DS1 converter complex serves as the standby. Each DS1 Converter complex consists of two TN574 boards or two TN1654 boards. A TN574 can be combined with a TN1654 in the same DS1 converter complex. It is also required that all four DS1 converter boards and interconnecting facilities that serve a PNC be of the same type. Note, however, that TN574 and TN1654 boards can coexist within the same system, they just can't be in the same fiber-link.

The two DS1 converter boards, TN1654 and TN574, use unique "Y" cables that are incompatible with each other.

A TN573B (or higher-suffixed) board must be used when connecting a SNI board to a TN1654 DS1 Converter board.

Table 95: Upgrading TN574 DS1 Converter Circuit Packs in a fiber-link to TN1654s — Duplicated PNC 1 of 2

Steps	Comments
Enter <code>status pnc</code> .	Verify that the A-PNC is active. If the B-PNC is active, enter the reset pnc interchange command to cause the A-PNC to go active.
Enter <code>busyout pnc-standby</code> .	Fiber link can be removed if PNC duplication is operational. Must busyout the standby PNC first.
Enter change system-parameters duplication. Change the <code>Enable Operation of PNC Duplication</code> field to <code>n</code> .	Disable PNC duplication.
Enter <code>list fiber-link</code> .	Determine the fiber-link number that the four TN574 circuit packs to be upgraded are associated with.
Enter <code>busyout fiber-link fiber#</code> .	<i>fiber#</i> represents the fiber-link number associated with the TN574 DS1 converter complexes that are being upgraded to TN1654 DS1 converter complexes.
Enter <code>remove fiber-link fiber#</code> .	
1 of 2	

Table 95: Upgrading TN574 DS1 Converter Circuit Packs in a fiber-link to TN1654s — Duplicated PNC 2 of 2

Steps	Comments
Remove the four TN574 DS1 converter circuit packs from the system.	
Replace the TN574 Y-cables with TN1654 Y-cables.	
Replace the removed TN574 DS1 converter circuit packs with TN1654 DS1 converter circuit packs. Prior to installing the TN1654 boards, review the prior section, <i>TN1654 Board Configuration Switch Settings</i> .	
If a TN1654 DS1 converter board is connected to an SNI board, upgrade the SNI to a TN573B or greater.	
Wait for the circuit packs to reset.	Red and green LEDs will light and then go out.
Enter <code>change circuit-packs cabinet#</code> . Update the screen to show that TN1654 boards are now being used instead of TN574 boards. Also update the connected SNI, if applicable, to suffix B.	<i>cabinet#</i> represents the cabinet associated with a DS1 converter board. The <i>change circuit-packs</i> screen needs to be updated for all four DS1 converter boards. Also, if needed, re-add translations for connected EI boards.
Enter <code>change system-parameters duplication</code> . Enter <code>y</code> in Enable Operation of PNC Duplication field.	Enable PNC duplication.
Enter <code>add fiber-link fiber#</code> to re-add the fiber-link using TN1654 DS1 converter circuit packs.	<i>fiber#</i> represents the fiber-link number associated with the TN574 DS1 converter complexes that are being upgraded to TN1654 DS1 converter complexes.
Enter <code>test alarms long clear</code> for category <code>exp-intf</code> .	
Wait 5 minutes for SNI-BD, SNI-PEER, FIBER-LK and DS1C-BD alarms to clear, or enter <code>clear firmware-counters a-pnc b-pnc</code> .	
Enter <code>status pnc</code> .	If either PNC's state of health is not "functional", consult the PNC-DUP section of the Maintenance Manual.
2 of 2	

Converting DS1-CONV Complex to Direct-Connect Fiber (duplicated PNC)

Note:

The following procedure is generic in its scope. Check the customer's switch configuration for EI/SNI structures.

Do not power down a Switch Node carrier to replace a circuit pack.

In duplicated PNC configurations, one DS1-CONV complex in the fiber-link serves as the active and the second DS1-CONV complex serves as the standby. Each DS1 Converter complex consists of two TN574 or TN1654 circuit packs.

Table 96: Convert from DS1-CONV to direct-connect fiber in a duplicated PNC 1 of 2

Step	Command/Step	Description
1.	<code>status pnc</code>	Verify that the A-side is active. <ul style="list-style-type: none"> 1 If the B-PNC is active, enter <code>reset pnc-interchange</code> 1 Then verify that the A-side is active (<code>status pnc</code>).
2.	<code>busyout pnc-standby</code>	Busyout the duplicated switch side.
3.	<code>change system-parameters duplication</code>	Disable PNC duplication by changing the <code>Enable Operation of PNC Duplication</code> field to <code>n</code> .
4.	<code>list fiber-link</code>	Lists administered fiber connections by number. Select the link number associated with the DS1-CONV complex that you are removing.
5.	<code>busyout fiber link n</code>	Busyout the fiber link of interest. The fiber link number (step 6) is <code>n</code> for this command.
6.	<code>remove fiber link n</code>	Remove the link administration for this link.
7.	<code>change circuit-pack cabinet</code>	Remove the DS1-CONV administration for the four designated circuit packs. <code>cabinet</code> is the cabinet number where these DS1-CONV complexes reside.
<i>1 of 2</i>		

Table 96: Convert from DS1-CONV to direct-connect fiber in a duplicated PNC 2 of 2

Step	Command/Step	Description
8.	Remove the DS1- CONV hardware.	Remove the 4 TN574 or TN1654 DS1-CONV circuit packs and Y-cables. The TN1654 and TN574 DS1-CONV boards use unique “Y” cables that are incompatible with each other. Reuse these cables only with the proper circuit pack.
9.	Install fiber-optic cable.	Add the lightwave transceivers (multimode 9823A or single-mode 300A) to match the lightguide fiber. Add these to the EIs and SNIs formerly connected to the DS1 converter circuit packs. Connect the lightwave transceivers with lightguide fiber.
10.	Check fiber-optic cable connections.	Ensure that the fiber-optic cables are securely connected to the lightwave transceivers that are attached to the designated circuit packs through the connections on the back of the cabinet.
11.	<code>add fiber-link n</code>	Administer the new EI/SNI fiber connection.
12.	<code>change system-parameters duplication</code>	Enable PNC duplication by changing the <code>Enable Operation of PNC Duplication</code> field to <code>y</code> .
13.	Enter <code>test alarms long clear</code> for category <code>exp-intf</code> .	
14.	Wait 5 minutes.	SNI-BD, SNI-PEER, FIBER-LK and EXP-INTF MOs need time to clear (or enter <code>clear firmware-counters a-pnc</code> or <code>b-pnc</code>)
15.	Enter <code>status pnc</code> .	If either PNC’s state of health is not functional, consult the PNC-DUP MO.
2 of 2		

Removing Fiber Connectivity to an PN

This procedure covers removing the connectivity to an PN or between SNs. Removing an PN and its associated carrier and circuit packs can be handled on a board-type basis.

If this system is duplicated, start with step 1; otherwise, start with step 6.

Note:

The following procedure is generic in its scope. Check the customer's switch configuration for EI/SNI structures.

Do not power down a Switch Node carrier to replace a circuit pack.

In duplicated PNC configurations, one DS1-CONV complex in the fiber-link serves as the active and the second DS1-CONV complex serves as the standby. Each DS1 Converter complex consists of two TN574 or TN1654 circuit packs.

Table 97: Removing Fiber Connectivity from a PN 1 of 2

Step	Command/Step	Description
1.	<code>status pnc</code>	Verify that the A-side is active. <ol style="list-style-type: none"> If the B-PNC is active, enter <code>reset pnc-interchange</code> Verify that the A-side is active (<code>status pnc</code>).
3.	<code>busyout pnc standby</code>	Busyout the duplicated switch side.
4.	<code>change system-parameters duplication</code>	Disable PNC duplication by setting the Enable Operation of PNC Duplication field to n .
5.	<code>list fiber-link</code>	List administered fiber connections by number. Record the endpoints (EIs, SNIs, and DS1Cs), and fiber link numbers that you are removing.
6.	<code>busyout fiber-link n</code>	Busyout the fiber link of interest. The fiber link number (step 4) is n for this command.
7.	<code>remove fiber-link n</code>	Remove the link administration for this link.
8.	<code>change system-parameters duplication</code>	Enable PNC duplication by changing the Enable Operation of PNC Duplication field to y .
9.	Physically remove the a-pnc and b-pnc fiber endpoint circuit packs	Physically remove EI, SNI, and DS1C circuit packs associated with the b-pnc.
1 of 2		

Table 97: Removing Fiber Connectivity from a PN 2 of 2

Step	Command/Step	Description
10.	<code>change circuit-pack</code>	Un-administer the PNC circuit packs.
11.	<code>clear firmware</code>	Clear any alarms or errors against those circuit packs.
12.	<code>status pnc</code>	Use <code>status pnc</code> to ensure that the PNC is in good health.
2 of 2		

Downgrading from Critical to High Reliability

The strategy this downgrade follows is to change from critical to high reliability. High reliability is actually duplication of the server, control network, and IPSIs without duplicate paths from IPSIs to CSS.

Table 98: Downgrading from Critical to High Reliability 1 of 2

Step #	Command/Step	Description
1.	<code>status pnc</code>	Check to see if A-side is active. If not: <ol style="list-style-type: none"> 1. Resolve any alarms against a-pnc. 2. <code>reset pnc-interchange</code> to activate a-pnc.
3.	<code>busyout pnc-standby</code>	Busyout the standby PNC.
4.	<code>change system-parameters duplication</code>	Disable PNC duplication by setting the Enable Operation of PNC Duplication field to n .
5.	<code>list fiber-link</code>	Lists administered fiber connections by number.
6.	<code>change fiber-link n</code>	<code>Change fiber</code> removes the b-pnc endpoints (EI, DS1Cs, if equipped). n is the number of the fiber from step 4. Repeat this step for every fiber from step 4.
1 of 2		

Table 98: Downgrading from Critical to High Reliability 2 of 2

Step #	Command/Step	Description
7.	Physically remove the b-pnc endpoint circuit packs	Start with the switch carrier most distant from the server. Physically remove EI, SNI, and SNC circuit packs associated with the b-pnc. Remove fiber cable not used for b-pnc carriers. See the following CAUTION.
8.	change circuit-packs	Update the translations for the removed circuit packs using change circuit-packs for the: <ul style="list-style-type: none"> 1 Cabinet with b-pnc SN carrier <ul style="list-style-type: none"> – SNIs – SNCs – EIs and DS1Cs, if any 1 Cabinet with b-pnc SN carrier <ul style="list-style-type: none"> – DS1Cs from port carrier 1 Cabinet with b-pnc EIs in every PN (also DS1Cs, if equipped)
9.	change cabinet UU	Remove the b-pnc SN carrier.
10.	Disable duplication.	Obtain a license file to disable PNC duplication.
2 of 2		

 **CAUTION:**

The removal of hardware and fiber cable will interrupt service.

Note:

At this point in the downgrade procedure, the system is in unduplicated mode and is operational. The physical removal of the SN carriers may be done at a time that is convenient for the customer. The next step in the downgrade is to follow the normal upgrade procedures from standard to high reliability.

Error log entries and recommended actions

Table 99: DS1C-BD Error Log Entries 1 of 2

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Recommended Action
0 (a)	0	Any	Any	Any	test board location

					2 of 2

Notes:

When problems persist, resetting the DS1 converter circuit pack via **reset board** may temporarily resolve the error condition and restore service until further assistance is provided.

- a. **Error Type 0:** Run the short test sequence first. If every test passes, run the long test sequence. Refer to each test's description, and follow its recommended procedures.
- b. **Error Type 1:** If the alarm is on board, then a major hardware error has occurred in a common part of the circuit pack, not circuit or packet specific. Replace the DS1 converter circuit pack.

If the alarm is off board, then either a major hardware error has occurred in a common part of the circuit pack, or a good clock signal could be recovered from the synchronization source. The synchronization source can be the fiber link or any one of the DS1 facilities.

1. Enter **display errors** and follow the associated repair procedures for any [SYNC \(Port Network Synchronization\)](#), [TDM-CLK \(TDM Bus Clock\)](#), and [SNC-BD \(Switch Node Clock Circuit Pack\)](#) errors.
 2. Enter **display errors** and follow the associated repair procedures for any [FIBER-LK \(Fiber Link\)](#) and [DS1-FAC \(DS1 Facility\)](#) errors.
 3. If the problem persists, replace the DS1 converter circuit pack.
- c. **Error Type 18:** the DS1 converter circuit pack has been busied out via **busyout board**. To resolve this error, release the DS1 converter circuit pack via the **release board**.

- d. **Error Type 25:** The 24/32-channel option switch setting on the TN1654 circuit pack does not match the administered Bit Rate on the fiber-link screen. If the on-board switch setting is wrong, the circuit pack must be physically removed to change the setting of the board option switch. If the administered bit rate is wrong, use **change fiber-link** to correct it.
- e. **Error Type 218:** The DS1 converter board is physically installed in a slot different than its administered slot. Remove the DS1 converter board and install it in its administered slot or execute **remove fiber-link** followed by **add fiber-link** to re-add the fiber-link setting the DS1 converter board's administered location to the physically installed slot.
- f. **Error Type 257:** A minor hardware error has occurred in a common part of the circuit pack, not circuit or packet specific. Replace the DS1 converter circuit pack.
- g. **Error Type 513, Aux Data 1:** A major hardware problem has occurred that affects only circuit data being received from the DS1 converter circuit pack. Replace the DS1 converter circuit pack.
- h. **Error Type 513, Aux Data 2:** A major hardware problem has occurred that affects only circuit data being transmitted from the DS1 converter circuit pack. Replace the DS1 converter circuit pack.
- i. **Error Type 513, Aux Data 3:** A major hardware problem has occurred that affects only packet data being received from the DS1 converter circuit pack. Replace the DS1 converter circuit pack.
- j. **Error Type 513, Aux Data 4:** A major hardware problem has occurred that affects only packet data being transmitted from the DS1 converter circuit pack. Replace the DS1 converter circuit pack.
- k. **Error Type 513, Aux Data 5:** A major lightwave transceiver transmit error occurred that affects data transmitted from the fiber link to the DS1 facility. Replace the DS1 converter circuit pack.
- l. **Error Type 769, Aux Data 1:** This error only applies to TN574 DS1 converter circuit packs.
 - If the alarm is on board, then a minor hardware problem has occurred that affects only circuit data being received from the DS1 converter circuit pack. Replace the DS1 converter circuit pack.
 - If the alarm is off board, then either a minor hardware problem has occurred that affects only circuit data being received into the DS1 converter circuit pack or a good clock signal cot be recovered from one of the DS1 facilities.
 1. Enter **display errors** and follow the associated repair procedures for any [SYNC \(Port Network Synchronization\)](#), [TDM-CLK \(TDM Bus Clock\)](#), and [SNC-BD \(Switch Node Clock Circuit Pack\)](#) errors.
 2. Enter **display errors** and follow the associated repair procedures for any [DS1-FAC \(DS1 Facility\)](#) errors.
 3. If the problem persists, replace the DS1 converter circuit pack.

m. **Error Type 769, Aux Data 2:** This error only applies to TN574 DS1 converter circuit packs.

If the alarm is on board, then a minor hardware problem has occurred that affects only circuit data being transmitted from the DS1 converter circuit pack. Replace the DS1 converter circuit pack.

If the alarm is off board, then either a minor hardware problem has occurred that affects only circuit data being transmitted from the DS1 converter circuit pack or a good clock signal can be recovered from the fiber channel.

1. Enter **display errors** and follow the associated repair procedures for any [SYNC \(Port Network Synchronization\)](#), [TDM-CLK \(TDM Bus Clock\)](#), and [SNC-BD \(Switch Node Clock Circuit Pack\)](#) errors.
2. Enter **display errors** and follow the associated repair procedures for any [EXP-INTF \(Expansion Interface Circuit Pack\)](#), [SNI-BD \(SNI Circuit Pack\)](#), and [FIBER-LK \(Fiber Link\)](#) errors.
3. If the problem persists, replace the DS1 converter circuit pack.

n. **Error Type 769, Aux Data 3:** *This error only applies to TN574 DS1 converter circuit packs.*

If the alarm is on board, then a minor hardware problem has occurred that affects only packet data being received from the DS1 converter circuit pack. Replace the DS1 converter circuit pack.

If the alarm is off board, then either a minor hardware problem has occurred that affects only packet data being received from the DS1 converter circuit pack or corrupted packets are being received from the packet facility.

1. Enter **display errors** and follow the associated repair procedures for any [EXP-INTF \(Expansion Interface Circuit Pack\)](#), [SNI-BD \(SNI Circuit Pack\)](#), and [DS1-FAC \(DS1 Facility\)](#) errors.
2. If the problem persists enter **display errors** and follow the associated repair procedures for any [SYNC \(Port Network Synchronization\)](#), [TDM-CLK \(TDM Bus Clock\)](#), and [SNC-BD \(Switch Node Clock Circuit Pack\)](#) errors.
3. If the problem still persists, replace the DS1 converter circuit pack.

o. **Error Type 769, Aux Data 5:** If the alarm is on board, then a minor FOI transmit error occurred that affects data transmitted from the fiber link to the DS1 facility. Replace the DS1 converter circuit pack.

If the alarm is off board, then either a minor FOI transmit error occurred that affects data transmitted from the fiber link to the DS1 facility. or corrupted packets are being received from the packet facility.

1. Enter **display errors** and follow the associated repair procedures for any [EXP-INTF \(Expansion Interface Circuit Pack\)](#), [SNI-BD \(SNI Circuit Pack\)](#), and [DS1-FAC \(DS1 Facility\)](#) errors.
2. If the problem persists enter **display errors** and follow the associated repair procedures for any [SYNC \(Port Network Synchronization\)](#), [TDM-CLK \(TDM Bus Clock\)](#), and [SNC-BD \(Switch Node Clock Circuit Pack\)](#) errors.

3. If the problem still persists, replace the DS1 converter circuit pack.
- p. **Error Type 769, Aux Data 6:** A minor FOI receive error occurred that affects data received from the DS1 facility and transmitted to the fiber link. Replace the DS1 converter circuit pack.
- q. **Error Type 769, Aux Data 7:** A minor on-board hardware failure exists on the processor/control hardware on the DS1 converter circuit pack. Replace the DS1 converter circuit pack.
- r. **Error Type 1281:** For TN574 DS1 converter boards, this error indicates that the facility masks or the clock reference masks do not match between the two DS1 converter circuit packs in the DS1 converter complex.

For TN1654 DS1 converter boards, this error indicates that the facility masks do not match between the two DS1 converter circuit packs in the DS1 converter complex.

Alarm should clear in 15 minutes.

1. If the problem persists, reset both DS1 converter circuit packs in the DS1 converter complex via **reset board**.
 2. If the problem persists, replace this DS1 converter circuit pack.
 3. If the problem persists, replace the DS1 converter circuit pack at the other end of the DS1 converter complex.
- s. **Error Type 1537:** The two TN574 DS1 converter circuit packs in the DS1 converter complex do not have the same firmware vintage. The TN574 DS1 converter with the older vintage should be replaced. This error does not apply to TN1654 boards.
- t. **Error Type 1793:** Fiber Loss of Frame Alignment (LFA) alarm occurred at the other end of the DS1 converter complex. The DS1 converter circuit pack at the other end of the DS1 converter complex got frame up on the signal coming into the circuit pack from the fiber. (The neighbor DS1 converter circuit pack detected the LFA and relayed this information to this DS1 converter circuit pack via the DS1 control channel.) The amber LED will flicker at a 5-Hz rate (on for 0.1 second, off for 0.1 second).
1. Execute **list fiber-link** to determine the Fiber Endpoint that is connected to the DS1 converter circuit pack. Enter **display errors** and follow the associated repair procedures for any [EXP-INTF \(Expansion Interface Circuit Pack\)](#) or [SNI-BD \(SNI Circuit Pack\)](#) errors for the Fiber Endpoints. Enter **display errors** and follow the associated repair procedures for any [FIBER-LK \(Fiber Link\)](#) errors for this fiber link.
 2. If the problem still persists, check for excessive slips and synchronization problems. Enter **display errors** and follow the associated repair procedures for any [SYNC \(Port Network Synchronization\)](#), [TDM-CLK \(TDM Bus Clock\)](#), and [SNC-BD \(Switch Node Clock Circuit Pack\)](#) errors.
 3. If the problem still persists, run the Far-End DS1 converter Circuit Pack Loopback test (#788) on this DS1 converter circuit pack via **test board location long**. This test indicates if the neighbor DS1 converter circuit pack hardware is functioning. If the test fails, replace the DS1 converter circuit pack at the other end of the DS1 converter complex.

4. If the problem still persists, run the Far-End Fiber Optic Terminator (lightwave transceiver) Loopback test (#789) on this DS1 converter circuit pack via **test board location long**. If this test fails, replace the lightwave transceiver that is connected to the neighbor DS1 converter circuit pack at the other end of the DS1 converter complex. If the neighbor board is connected to the Fiber Endpoint via metallic cable, this test aborts.
 5. If the problem still persists, replace connectors and the cable between the neighbor DS1 converter circuit pack and the Fiber Endpoint at the other end of the DS1 converter complex. The cable may be a fiber or a metallic cable.
- u. **Error Type 2049:** Fiber Loss of Signal (LOS) alarm occurred at the other end of the DS1 converter complex. The DS1 converter circuit pack at the other end of the DS1 converter complex does not detect a signal coming into the circuit pack from the fiber. (The neighbor DS1 converter circuit pack detected the LOS and relayed this information to this DS1 converter circuit pack via the DS1 channel.) The amber LED will flicker at a 5-Hz rate (on for 0.1 second, off for 0.1 second).
1. Execute **list fiber-link** to determine the Fiber Endpoints that are connected to both ends of this DS1 converter complex. Enter **display errors** and follow the associated repair procedures for any [EXP-INTF \(Expansion Interface Circuit Pack\)](#) or [SNI-BD \(SNI Circuit Pack\)](#) errors for the Fiber Endpoints that are administered on this fiber link, and Enter **display errors** and follow the associated repair procedures for any [FIBER-LK \(Fiber Link\)](#) errors for this fiber link.
 2. If the problem still persists, run the Far-End DS1 converter circuit pack loopback test (#788) on this DS1 converter circuit pack via **test board location long**. This test shows if the neighbor DS1 converter circuit pack hardware is functioning. If this test fails, replace the DS1 converter circuit pack at the other end of the DS1 converter complex.
 3. If the problem still persists, run the Far-End Fiber Optic Terminator (lightwave transceiver) Loopback test (#789) on this DS1 converter circuit pack via **test board location long**. If this test fails, replace the lightwave transceiver that is connected to the neighbor DS1 converter circuit pack. If the neighbor board is connected to the Fiber Endpoint via metallic cable, then this test will abort.
 4. If the problem persists, replace connectors and the cable between the neighbor DS1 converter circuit pack and the Fiber Endpoint at the other end of the DS1 converter complex. The cable may be fiber or metallic.
- v. **Error Type 3329:** This error indicates that excessive slips have occurred on the fiber link between the DS1 converter board and the Fiber Endpoint. See [SYNC \(Port Network Synchronization\)](#) for diagnosing slip problems.

Demand test descriptions and error codes

Investigate tests in the order presented. By clearing errors associated with the first test, errors generated from other tests may also be cleared. Click on the link to see the full description of the test, error codes, and recommended actions.

Tests 788 and 789 are executed by the TN574 DS1 Converter circuit pack only.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND ¹
Failure Audit Test (#949)	X	X	ND
DS1 Facilities Connectivity Test (#790)		X	D
Far-End DS1 Converter Circuit Pack Loopback Test (#788)		X	D
Far-End Lightwave Transceiver Loopback Test (#789)		X	D
DS1C Board Options Audit (#795)	X	X	ND
The following test is executed as part of the <code>reset board</code> command			
Reset Board Test (#787)			D

1. D = Destructive; ND = Nondestructive

Note:

Test #984 is not an actual demand maintenance test. This test number reports the results from `clear firmware-counters`. Refer to the table for [Failure Audit Test \(#949\)](#) to interpret ABORT codes for Test #984.

DT-LN-BD (Data Line Circuit Pack)

MO Name in Log	Alarm Level	Initial Command to Run	Full Name of MO
DT-LN-BD	MIN WRN	<i>test board location</i>	Data Line circuit pack

See [XXX-BD \(Common Port Circuit Pack/Media Module\)](#) for circuit pack-level errors.

See [DAT-LINE \(Data Line Port\)](#) for related line information.

DTMR-PT (Dual-Tone Multifrequency Receiver Port)

MO Name in Log	Alarm Level	Initial Command to Run	Full Name of MO
DTMR-PT	MAJ MIN	<code>test port location</code>	Dual-Tone Multifrequency Receiver port (TTR)
	WRN	<code>release port location</code>	

Dual-Tone Multifrequency Receiver ports (DTMR), also known as Touch-Tone Receivers (TTRs), reside on the following circuit packs:

- 1 TN748
- 1 TN420
- 1 TN756
- 1 TN744B and TN744C
- 1 TN2182
- 1 TN2312AP
- 1 TN2312BP

There are four Dual-Tone Multifrequency Receiver (DTMR-PT) ports and two General Purpose Tone Detector (GPTD-PT) ports on the TN748, TN420 and TN756 Tone Detector packs. There are eight GPTD-PT ports on each TN744, TN2182 and TN2312AP circuit packs.

The GPTD ports can be used for TTR, call progress tone detection, call prompting, MF signaling, dial tone detection, CO answer detection and OCM call classification.

The DTMR port is used to detect touch-tone digits that are placed on the Time Division Multiplex (TDM) bus. Examples of touch-tone digits are digits 0 through 9, digit #, and digit *. The ability of the DTMR port to detect touch-tone digits is essential in placing a station-to-station call. Calls originating from a hybrid station *do not* require a DTMR port.

For any Tone Detector circuit-level error (DETR-BD), see [XXX-BD \(Common Port Circuit Pack/Media Module\)](#).

Error log entries and recommended actions

Table 100: DTMR-PT Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Recommended Action
0 (a)	0	Any	Any	Any	<i>test port location</i>
1 (d)	17664	Tone Detector Audit/ Update test (#43)	MAJ MIN (b)	ON	<i>test port location r 2</i>
18	0	<i>busyout port location</i>	WRN	ON	<i>release port location</i>
130 (e)		None	WRN	ON	<i>test port location r 2</i>
257 (c)	17666	Tone Detector Audit/ Update test (#43)	MAJ MIN (b)	ON	<i>test port location r 3</i>
513 (d)	Any	Tone Detection Verification test (#42)	MAJ MIN (b)	ON	<i>test port location r 3</i>

Notes:

- a. **Error Type 0:** Run the short test sequence first. If every test passes, run the long test sequence. Refer to each test's description, and follow its recommended procedures.
- b. There are two possible alarm levels for this error. A Major alarm is raised if the total number of DTMR ports currently in service is less than or equal to 1/2 of the administered threshold number. Otherwise, a Minor alarm is raised. In either case, run the short test sequence against the DTMR port and follow the repair procedures for the individual tests.

The threshold number of DTMR ports for service is administered using **change system-parameters maintenance**.
- c. **Error Type 257:** The DTMR port lost its translation. Testing the DTMR port is sufficient to reload its translation. If testing the DTMR port does not clear the error, then the IPSI or Tone Detector circuit pack containing the defective DTMR port should be replaced.
- d. **Error Type 513:** The DTMR port is having problems detecting touch-tone digits. If this error is being constantly logged, the IPSI or Tone Detector circuit pack containing the defective DTMR port should be replaced.
- e. **Error Type 130:** The circuit pack has been removed or has been insane for at least 11 minutes. To clear the error, reinsert or replace the circuit pack.

Demand test descriptions and error codes

Investigate tests in the order presented. By clearing errors associated with the first test, errors generated from other tests may also be cleared. Click on the link to see the full description of the test, error codes, and recommended actions.

Order of Investigation	Short Test Sequence	Long Test Sequence	D/ND ¹
Tone Detection Verification Test (#42)	X	X	ND
Tone Detector Audit/Update Test (#43)	X	X	ND

1. D = Destructive; ND = Nondestructive

E-DIG-BD (Multi Application Platform Board)

MO Name in Log	Alarm Level	Initial Command to Run	Full Name of MO
E-DIG-BD	MIN WRN	<i>test board location</i>	MAPD Board

See [XXX-BD \(Common Port Circuit Pack/Media Module\)](#) for circuit pack-level errors.

See [E-DIG-ST \(Emulated Digital Line\)](#) for related line information.

E-DIG-ST (Emulated Digital Line)

MO Name in Log	Alarm Level	Initial Command to Run	Full Name of MO
E-DIG-ST	MIN	<code>test port location 1</code>	Emulated Digital Station
	WRN	<code>test port location</code>	

E-DIG-ST maintenance monitors and tests ports on the TN800 MAPD circuit pack and the hardware connected to those ports for lines administered as a digital station. Stand-alone data modules and data adaptors in stand-alone mode are not supported by the TN800 circuit pack.

Error log entries and recommended actions

Table 101: E-DIG-ST Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Recommended Action
0 (a)	0	Any	Any	Any	<code>test port location</code>
18 (b)	0	<code>busyout port location</code>	WRN	OFF	<code>release port location</code>
130 (c)			WRN	ON	<code>test port location</code>
257 (d)	40971				
1537 (e)	40968		WRN	OFF	
1793 (f)		Voice and Control Local Loop test (#13)	MIN WRN ¹	ON	<code>test port location 1 r 3</code>
2049 (g)		GPP NPE Crosstalk Test (#9)	MIN WRN ¹	ON	<code>test port location 1 r 3</code>
2305 (h)	32770				
3840 (i)	40965				
3841 (j)	41029				
2304 (k)					

1. Major alarms may be downgraded to Warning alarms based on the value used in `set options`.

Notes:

- a. **Error Type 0:** Run the short test sequence first. If every test passes, run the long test sequence. Refer to each appropriate test's description, and follow its recommended procedures.
- b. **Error Type 18:** Maintenance personnel have busied out the port in question. Release the port by using `release port location`.
- c. **Error Type 130:** The circuit pack has been removed or has been insane for more than 21 minutes. To clear the error, reinsert or replace the circuit pack.
- d. **Error Type 257:** Problems transmitting to the voice terminal. This problem can be caused by defective wiring that can cause varying degrees of problems on different types of sets. Sets such as the 7410 appear to be more susceptible to wiring problems than others.
- e. **Error Type 1537:** There is a problem with the link to the voice terminal. This can be ignored if no user complaints are received. Otherwise, make sure the voice terminal is connected, check for defective wiring, check for a defective voice terminal, and move voice terminal to a jack that is closer to the switch (number of feet of wiring between the jack and the switch). If the problem still exists, replace the circuit pack. Once the problem has been resolved, the alarm is retired after a predetermined amount of time.
- f. **Error Type 1793:** The local loop test failed. Each failure increments an internal counter by 1 when the local loop test fails. The counter is decremented when the loop test passes. When the counter reaches a threshold of 3, an on-board MINOR alarm is raised.
- g. **Error Type 2049:** The NPE Crosstalk test failed. The internal counter increments by 1 when the NPE Crosstalk test fails. The counter is decremented by 1 when the NPE Crosstalk test passes. When the counter reaches a threshold of 3, an on-board MINOR alarm is raised and the board is taken out of service.
- h. **Error Type 2305:** The station went off-hook while it was in the ready-for-service state. Use `status station` to determine the state of the station. The off-hook should have moved the station to ready-for-service. No action is necessary.
- i. **Error Type 3840:** No terminal is connected to the Digital Line board. No maintenance action is required.
- j. **Error Type 3841:** The circuit pack's message buffer is full. This may be caused by having many display phones with heavy traffic connected to the circuit pack. No action is necessary.
- k. **Error Type 2304:** Internal system error. No action is necessary.

Demand test descriptions and error codes

1. D = Destructive; ND = Nondestructive

EMG-XFER (Emergency Transfer)

MO Name in Log	Alarm Level	Initial Command to Run ¹	Full Name of MO
EMG-XFER	MAJ WRN	<code>test environment UU</code>	Emergency Transfer

1. *UU* is the universal cabinet number listed in the PORT field of the Alarm or Error Log.

The maintenance software for Emergency Transfer monitors the position of the Emergency Transfer switch(es) on the EPNs' Maintenance circuit packs. It does not monitor whether the system is actually in Emergency Transfer.

Emergency Transfer (ET) provides the ability to connect designated analog phones to CO trunks when the switch cot provide minimal phone service.

Emergency Transfer is automatically controlled by the system or can be manually controlled via the Emergency Transfer switch located on the Maintenance circuit pack. A manual ON position (up) generates a Major alarm. A manual OFF position (down) generates a Warning alarm. Unless a technician is currently working on the system, the switch should be left in the auto position.

Emergency Transfer Status

The `status cabinet UU` command shows the location of the ET switches and the current status of ET in the designated cabinet as follows:

auto+	ET is invoked and under system control.
auto-	ET is not in effect and is under system control (normal operating state).
unavailable	The switch setting(s) is not available.

Error log entries and recommended actions

Table 102: EMG-XFER Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Recommended Action
0 (a)	0	Any	Any	Any	<code>test environment UU</code>
1 (b)	0	Emergency Transfer Query (#124)	MAJ	ON	<code>test environment UU r 3</code>

1. D = Destructive, ND = Nondestructive

EPN-SNTY (PN Sanity Audit)

MO Name in Log	Alarm Level	Initial Command to Run	Full Name of MO
EPN-SNTY	None	None	EPN Sanity Audit

The EPN Sanity Audit feature enhances the system's ability to recover from failure conditions that disable an entire PN. In such situations, not only is the affected PN unable to provide service to the system, but the system itself has not detected the condition. The EPN Sanity Audit feature recognizes a PN as unable to provide service when the software cot receive control messages from PN circuit packs. When such a failure is detected by the EPN Sanity Audit, a sequence of recovery actions is triggered to restore the PN to service.

For a standard-reliability system (unduplicated server), the recovery sequence is:

1. TDM bus switch
2. EPN WARM reset
3. EPN COLD reset

The recovery sequence is:

1. TDM bus switch
2. Tone-Clock switch within the PN
3. PNC interchange
4. PN WARM reset
5. PN COLD reset

The EPN Sanity Audit feature activates only when every existing maintenance operation has failed to detect the PN problem. The EPN Sanity Audit serves as a safety net for the PN.

Note:

It is not clear why certain types of PN problems activate this feature. Error log entries related to these problems do not specify which hardware to replace. The error log entries only indicate that some drastic recovery action occurred due to an unknown problem. Clues as to the root cause of the PN outage may be present in the Error Logs and the Alarm Logs of the following MOs: [TDM-BUS \(TDM Bus\)](#), [EXP-INTF \(Expansion Interface Circuit Pack\)](#), [TDM-CLK \(TDM Bus Clock\)](#), [EXP-PN \(Expansion Port Network\)](#), and [PNC-DUP \(PNC Duplication\)](#). Refer to these maintenance sections during troubleshooting operations.

Error log entries and recommended actions

Table 103: EPN-SNTY Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Recommended Action
0 (a)	0	Any			None
8801 (b)	Any				
8803 (c)	Any				
9901 (d)	Any				
9902 (e)	Any				
9903 (f)	Any				
9904 (g)	Any				
9905 (h)	Any				

Notes:

- a. **Error Type 0:** Run the short test sequence first. If every test passes, run the long test sequence. Refer to each appropriate test's description, and follow its recommended procedures.
- b. **Error 8801:** the PN is unable to send uplink control messages, and the control channel of the PN's TDM bus is swapped as part of the recovery procedure.
- c. **Error 8803:** the PN is unable to send uplink control messages and the PN's Tone-Clock is swapped as part of the recovery procedure.
- d. **Error 9901:** the PN is unable to send uplink control messages, but recovers after the control channels of the PN's TDM bus are swapped.
- e. **Error 9902:** the PN is unable to send uplink control messages, but recovers after the PN's active Tone-Clock is swapped.
- f. **Error 9903:** the PN is unable to send uplink control messages, but recovers after a PNC interchange has taken place.
- g. **Error 9904:** the PN is unable to send uplink control messages, but recovers after a PN WARM reset.
- h. **Error 9905:** the PN is unable to send uplink control messages, but recovers after a PN COLD reset.

ERR-LOG (Error Log)

MO Name in Log	Alarm Level	Initial Command to Run	Full Name of MO
ERR-LOG	none	none	Error Log

The ERR-LOG MO is responsible for the sanity of the Alarm Log, the Hardware Error Log, and the Software Error Log. If an inconsistency is detected in any one of these logs, every log will be re-initialized and a hardware error will be logged against ERR-LOG indicating the time of inconsistency. There are no tests and no alarms for the Error Log MO. It exists solely for the purpose of allowing errors to be logged against it.

Error Log Entries

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Recommended Action
510 (a)	See Note		none	none	none

Notes:

- a. **Error Type 510:** An inconsistency was detected in either the Alarm Log, the Hardware Error Log, or the Software Error Log. The system attempts to recover the logs but, depending on the extent of the corruption, some or all entries in the logs may be lost. Any alarms that were active at the time of this error have been cleared. There is no associated test for this error.

The Aux Data value indicates when the inconsistency was found:

0	During a periodic audit of the Error Log
1	After an extended reboot
2	After a reboot
3	After a Reset System 3 (Cold_1)
4	After a Level-3 System Reset (Cold_1)
4	After a Reset System 2 (Cold_2)
8	After a Level-2 System Reset (Cold_2)
16	After a Level-1 System Reset (Warm Start)
100	After an internal software audit
2500	After a single-process (MDM) restart

Survivable Core Server

MO Name in Log	Alarm Level	Initial Command to Run	Full Name of MO
Survivable Core Server	MAJ MIN	None	Survivable Core Server

The Survivable Core Server maintenance object (MO) monitors the status of the Survivable Core Server feature.

On the Main server, the MO will:

- 1 Monitor the registration status for all administered Survivable Core Servers. The commands `display survivable-processor` and `display system-parameters port-networks` list the administered Survivable Core Servers. The registration status of all Survivable Core Servers is initially checked approximately ten minutes after the Main boots up. Subsequent to this, the registration status for all Survivable Core Servers is monitored each time a Survivable Core Server registration status change is received at the Main server.

On a Survivable Core Server, the MO will:

- 1 Monitor the registration status of the active server within a Survivable Core Server. Only the active server of a Survivable Core Server server pair will register with the active Main server. The Survivable Core Server MO at a Survivable Core Server does not track the registration status of other Survivable Core Servers.
- 1 Monitor the IP Server Interface (IPSI) socket connections for all administered IPSI circuit packs. Each Survivable Core Server establishes a socket connection to all administered IPSI circuit packs. These connections advertise the Survivable Core Server administered values to all IPSIs. If needed, the IPSI will use this socket connection to request service from the Survivable Core Server.

Error log entries and recommended actions

Table 104: Survivable Core Server Error Log Entries 1 of 2

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Recommended Action
1 (a)		None	MAJ	OFF	Survivable Core Server controlling Port Network(s). Resolve any server and/or network problems. Schedule or initiate an on-demand switchback of Port Networks to the Main server.
					1 of 2

Table 104: Survivable Core Server Error Log Entries 2 of 2

Error Type	Aux Data	Associated Test	Alarm Level	On/Off Board	Recommended Action
257 (b)		None	MIN	OFF	Survivable Core Server is not registered. Resolve any server and/or network problems.
513 (c)		None	MIN	OFF	Connection not established between Survivable Core Server and IPSI. Resolve any Survivable Core Server and/or network problems. Use the PING command to verify connectivity to IPSI circuit packs.
769 (d)		None	MIN	OFF	<p>This alarm is raised when a main server has administration for a duplicated Survivable Core Server that is missing the Server A IP address.</p> <p>Typically, this alarm is raised after an upgrade from a pre-CM 5.2 Release to a CM 5.2 or later Release.</p> <p>To retire the alarm, use the change survivable-processor command to administer the Server A IP address for each Duplicated Survivable Core Server.</p>
					2 of 2

Notes:

- a. **Error Type 1:** This error only applies to a Survivable Core Server. A Survivable Core Server has become the master of an IPSI Port Network.

Investigate and attempt to retire the alarm with the following steps:

1. Avaya Fault and Performance Management can be used to obtain a network view of the Survivable Core Server configuration. Note any network fragmentation or server outages (Main or Survivable Core Server).
2. Use the SAT command **status ess port-network** to identify which Survivable Core Server Cluster IDs each Port Network (IPSI) is connected to. This command may be executed on either a Main server or Survivable Core Server. With a fragmented network, it may be necessary to execute this command on each server in the system configuration to acquire a complete view of IPSI connectivity.
3. Using either Avaya Fault and Performance Management or SAT sessions to each server, determine the extent of any server or network outages.
4. Resolve any server outages. If possible, bring the Main server(s) back online first.

Note:

Bringing a Main server back online will not cause Port Networks to immediately switch back to it. Restoring Port Network control to a Main server in a stable network requires proactive interaction. See step 7 below.

5. Resolve network fragmentation and outage issues per local practice.
6. Use either Avaya Fault and Performance Management or the SAT commands `status ess port-network` and `status ess clusters` to verify that all servers and network resources are operational.

 **CAUTION:**

Entering the commands below will cause a service interruption. When Port Networks switch to either a Main server or Survivable Core Server, a level 2 restart is initiated on the Port Network, and service will be interrupted to the entire Port Network. Note that shuffled IP to IP calls will not be dropped, but during the restart, they will not have any access to features (Hold, Transfer, Conference, etc.).

7. When the Main server(s) and network are operational and stable, schedule or initiate an on-demand switchback of Port Networks to the Main server. On the Main server, use these commands:

Note:

ATM PNC

When a Port Network which is providing control for other sub-tending Port Networks via an ATM Expansion Interface (ATM-EI) circuit pack switches to a server, the other sub-tending Port Networks may or may not end up being controlled by the same server. All IPSI controlled Port Network(s) in the configuration will vie for control of the sub-tending Port Networks. The only way to guarantee that ATM-EI controlled Port Networks will be controlled by the same server is if all IPSI controlled Port Networks are controlled by that same server.

1. Schedule a switchback to the Main with the `change system-parameters ess` command. See *Avaya Aura™ Communication Manager Survivable Options* for more information. The **Auto Return** field may be set to `scheduled` or `no`. If `no` is used, the only way to initiate a switchback is by using an on-demand command (See below). The `survivable-processor` and `system-parameters port-networks` administration screens may be displayed on all Survivable Core Servers but may only be changed on the Main server.
1. Initiate an on-demand switchback by entering the `get forced-takeover ipserver-interface port-network N` command. This command may be issued with a qualifier for *a11* Port Networks or a single individual `port-network N`.

- b. **Error Type 257:** This error applies to a Main or Survivable Core Server. This error is generated when a Survivable Core Server is translated on the Main but is NOT registered with the Main.

For detailed information on maintenance commands, see *Maintenance Commands Reference (03-300431)*.

For detailed information on administration commands, see *Avaya Aura™ Communication Manager Survivable Options*.

Follow these steps to investigate and attempt to retire the alarm:

On the Main server:

1. Enter `display survivable-processor` and `display system-parameters port-networks` to verify that the Survivable Core Server is properly administered. a Survivable Core Server must be administered on the Main server before it can register with the Main server. Record these values for troubleshooting the Survivable Core Server.
2. On the SAT, enter `ping ip-address board <location> nnn.nnn.nnn.nnn` to verify connectivity between the Main server and the Survivable Core Server, where *board* is the location of the C-LAN circuit pack the Survivable Core Server is trying to register with and *nnn.nnn.nnn.nnn* is the IP address of the Survivable Core Server .
3. Use the `display events` command with a **category** of **denial** to display denial events related to Survivable Core Server. The Survivable Core Server registration denial events are in the 36xx range. See Survivable Core Server Denial Events in *Avaya Aura™ Communication Manager Denial Events (03-602793)* for descriptions of individual Survivable Core Server denial events.
4. Use the `list trace ras ip-address` command to monitor registration requests from the Survivable Core Server. This command displays registration requests from the Survivable Core Server and the associated response from the Main server. Note that under normal operation a Keep-Alive (KA) message is periodically sent from the Survivable Core Server to the Main server. This should not be confused with a registration failure.
5. Firewalls or other security measures may prevent the Main server and Survivable Core Server from communicating. Verify that these ports are open through the network between the Main server and the Survivable Core Server:
 - 1 1719 Registration between the Survivable Core Server and the Main.
 - 1 21874 Filesync (rsync) between the Main server and Survivable Core Server.

On the Survivable Core Server that is not registered:

 **CAUTION:**

In the next steps, be careful to use the **Close Window** button to cancel out of the **Configure Server** page to avoid a reboot of the Survivable Core Server. Do not Update the system.

6. Use the bash `ping nnn.nnn.nnn.nnn` command to verify connectivity between the Survivable Core Server and Main servers, where `nnn.nnn.nnn.nnn` is the IP address of the C-LAN in the Main server that the Survivable Core Server is trying to register with. To determine which IP address the Survivable Core Server is attempting to register with, enter the **Configure Server** command from the Maintenance Web Interface on the Survivable Core Server to display the **configure ESS** screen.
7. Firewalls or other security measures may prevent the Main server and Survivable Core Server from communicating. Verify that these ports are open through the network between the Main and the Survivable Core Server:
 - 1 1719 Registration between the Survivable Core Server and the Main server.
 - 1 21874 Filesync (rsync) between the Main server and Survivable Core Server.
8. On the Maintenance Web Interface **Configure Server** pages:
 - 1 On the **Set Identities** page, verify that the correct Server ID (SVID) is entered. This should be a unique value for each server. The SVID must be between 1 and 99. Gaps in the SVIDs for a configuration are allowed (10, 20, 30,...) but the servers may be consecutively numbered if desired. Each server in the system, duplex or simplex, Main or Survivable Core Server, requires a unique SVID.
 - 1 On the **Configure ESS** page, verify that the correct platform type is selected and the correct C-LAN and Main server IP addresses are entered. The Survivable Core Server will use these addresses to establish a connection with the Main server and register. On the Main server, enter **display survivable-processor** and **display system-parameters port-networks** to verify that the Survivable Core Server is properly administered. A Survivable Core Server must be administered on the Main server before it can register with the Main server. Record these values for troubleshooting the Survivable Core Server.
 - 1 On the **status Summary** page, verify that the Cluster ID is correct. Verify that the individual server IDs are correct.

Note:

Note: The individual server IDs should be the same as those entered on the **Set Identities** page of the Configure Server procedure.

9. On the SAT, enter `display system-parameters customer-options`.
 - 1 Verify that the **ESS Administration** field is set to **y**.
 - 1 Verify that the **Enterprise Survivable Server** field is set to **y**.

 **Tip:**

Customer options may only be set with the Communication Manager license file. If the fields above are incorrect, obtain a new license file with corrected data.

10. From the Maintenance Web Interface, click on the **License File** command. Verify that the license mode is **normal**.
11. Use the SAT command **status ess clusters** to verify that a translation file has been sent to this Survivable Core Server. The translation file is only sent after a successful registration. If a translation file has never been sent, it is an indication of either serious network connectivity issues or Communication Manager administration and/or configuration errors. See above.

Note:

It may take several minutes for the Survivable Core Server to register with the Main server.

- c. **Error Type 513:** This error only applies to a Survivable Core Server. A socket connection cannot be established between the Survivable Core Server and an IPSI.
 1. On the Maintenance Web Interface, use the **ipsiversion** command to verify that all IPSIs have the current hardware and firmware. See the Minimum Firmware/Hardware Vintages document found at: <http://support.avaya.com>
 2. From the Maintenance Web Interface pages of the Survivable Core Server that is not connecting, initiate a **PING** to the administered IPSIs to verify connectivity between the Survivable Core Server and IPSIs.
 3. Firewalls or other security measures may prevent the server and IPSI from communicating. Verify that these ports are open through the network between the server and the IPSI:
 - 1 5010 IPSI / Server control channel
 - 1 5011 IPSI / Server IPSI version channel
 - 1 5012 IPSI / Server serial number channel
 4. Use **status ess port-network** to identify which Survivable Core Server Cluster IDs a Port Network (IPSI) is connected to. This command may be executed on either a Main server or Survivable Core Server. With a fragmented network, it may be necessary to execute this command on each server in the system configuration to acquire a complete view of IPSI connectivity. [Figure 24: status ess port-networks example](#) shows an IPSI (the standby IPSI in PN 2) that does not have a connection established with the server.

Figure 24: status ess port-networks example

```

status ess port-networks

Cluster ID 1          ESS PORT NETWORK INFORMATION

   Com  Intf  Intf  Port  IPSI  Pri/  Pri/  Cntl  Connected
  PN Num Loc  Type Ste  Loc  Sec  Sec  Clus  Clus(ter)
                ID  IDs
1    1  1B01  IPSI  up   1B01  1AXX  standby  1    1    44  64  13  9    200 100 500
                1B01  actv-aa  1    1    44  64  13  9    200 100 500
2    1  2AXX  IPSI  up   2AXX  2AXX  actv-aa  1    1    44  64  13  9    200 100 500
                2B01  standby  *    *    44  64  13  9    200 100 500

                4B01  standby  1    1    44  64  13  100 500 850 9
5    1  5A01  EI    up   3AXX

Command successfully completed
Command:

```

5. Resolve network fragmentation and outage issues per local practice.
 6. Enter the SAT command **status ess port-network** to verify that all Port Networks (IPSIs) are communicating with servers.
- d. **Error Type 769:** If the main Survivable Core Server detects a Survivable Core Server administration for a duplicated Survivable Core Server which is missing the server A IP address, an alarm is raised.
- In a translation upgrade, as the Main Survivable Core Server detects Survivable Core Server administration for a duplicated Survivable Core Server, an alarm is always raised after the upgrade to a Survivable Core Server system that has duplex ESSs.
- Demand test descriptions and error codes

There are no demand tests for the Survivable Core Server maintenance object. The following table contains the explanation of the error codes from Tests 1605, 1606, and 1607 on the **TEST RESULTS** screen which is displayed from the following commands:

- ```

| enable ess
| disable ess

```

| `get forced-takeover ipserver-interface`

| Error Code | Description                                                                                                                                               |
|------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1991       | Requested Survivable Core Server cluster is not administered.                                                                                             |
| 1992       | Requested Survivable Core Server cluster is not registered.                                                                                               |
| 1993       | Requested Survivable Core Server is controlling an IPSI PN.                                                                                               |
| 1994       | A Survivable Core Server cluster may not enable/disable other clusters (Survivable Core Server or main). It can only change its own enable/disable state. |
| 1995       | Survivable Core Server cluster is disabled.                                                                                                               |
| 1996       | Port network does not exist.                                                                                                                              |
| 1997       | Not an IPSI port network                                                                                                                                  |
| 2500       | Internal operation failed                                                                                                                                 |
|            |                                                                                                                                                           |

## ETH-PT (Control LAN Ethernet)

| MO Name in Log | Alarm Level | Initial Command to Run         | Full Name of MO |
|----------------|-------------|--------------------------------|-----------------|
| ETH-PT         | MAJ<br>MIN  | <i>test port location long</i> | Ethernet Port   |
|                | WRN         | <i>test port location</i>      |                 |

The TN799DP Control LAN (C-LAN) circuit pack provides TCP/IP connection to adjunct applications such as CMS, INTUITY, and DCS Networking. The C-LAN circuit pack has one 100BASE-T Ethernet connection and up to 16 DS0 physical interfaces for PPP connections. Multiple C-LAN circuit packs in a system provide additional TCP/IP capacity.

A RSCL (remote socket control link) links the C-LAN and the server to pass call-control and other management information. Since one link serves every port on the circuit pack, maintenance of the RSCL is part of the C-LAN circuit pack's maintenance.

---

## Control LAN Congestion Controls

The switch activates congestion controls on the C-LAN when it detects buffers exceeding the threshold. The switch releases the congestion controls when the C-LAN reports that its buffers have returned to normal levels.

| If congestion:                    | Then the switch:      |
|-----------------------------------|-----------------------|
| Persists for a 14-minute interval | Raises a MINOR alarm  |
| Exhausts buffers                  | Raises a MINOR alarm  |
| Ceases for 12 minutes             | Retires a MINOR alarm |

## Error log entries and recommended actions

**Table 105: ETH-PT Error Log Entries**

| Error Type        | Aux Data | Associated Test                        | Alarm Level             | On/Off Board | Recommended Action                    |
|-------------------|----------|----------------------------------------|-------------------------|--------------|---------------------------------------|
| 0 (a)             | 0        | Any                                    | Any                     | Any          | <code>test port location</code>       |
| 1 (b)             | 0        | Ethernet Local Looparound Test (#1278) | MIN                     | ON           | <code>test port location 1 r 3</code> |
| 513 (c)           | 0        | Link Integrity Inquiry Test (#1282)    | MIN                     | OFF          | <code>test port location r 3</code>   |
| 769 (d)           | 0        |                                        | WRN                     | OFF          |                                       |
| 1281 (e)          | 0        |                                        |                         |              |                                       |
| 1537<br>1538 (f)  |          | Session Status test (#1286)            | MIN                     | OFF          |                                       |
| 1793–<br>1920 (g) |          |                                        |                         |              |                                       |
| 2305–<br>2560 (h) |          |                                        |                         |              |                                       |
| 2561–<br>2816 (h) |          |                                        |                         |              |                                       |
| 3329 (i)          |          | TCP/IP Ping test (#1281)               | MIN<br>WRN <sup>1</sup> | OFF          | <code>test port location r 3</code>   |

1. Major alarms may be downgraded to Warning alarms based on the value used in `set options`.

### Notes:

- a. **Error Type 0:** Run the short test sequence first. If every test passes, run the long test sequence. Refer to each appropriate test's description, and follow its recommended procedures.
- b. **Error Type 1:** Ethernet Local Looparound Test (#1278) failed.
  1. Test the port (`test port location long`).
  2. See [Ethernet Local Looparound Test \(#1278\)](#) for repair procedures.
- c. **Error Type 513:** Link Integrity Inquiry test (#1282) failed, or the C-LAN port detected loss of Ethernet link integrity.
 

Possible causes:

  - 1 Cables
  - 1 Ethernet transceiver
  1. Test the port (`test port location long`).
  2. If the [Link Integrity Inquiry Test \(#1282\)](#) fails, refer to its repair procedure.

d. **Error Type 769:** Port received invalid frame.

Invalid Ethernet frame errors occur when the frame:

- 1. Contains a bad cyclic redundancy check (CRC)
  - 1. Is misaligned
1. Isolate the problem with the [Ethernet Local Looparound Test \(#1278\)](#).
  2. Test the port (`test port location long`).
  3. Verify the repair with the [Ethernet Local Looparound Test \(#1278\)](#).
  4. Clear the alarm (`test port location long clear`).

e. **Error Type 1281:** System software received an indication that the far end has requested a disconnect of a session on this link. This is a log-only error. No action is necessary.f. **Error Type 1537–1538:** Some or all sessions on a port are down.

| If:                    | Then the switch raises:       |
|------------------------|-------------------------------|
| Some sessions are down | WARNING alarm on circuit pack |
| Every session is down  | MINOR alarm on circuit pack   |

1. Test the port (`test port location`).
  2. Refer to [Session Status Test \(#1286\)](#) repair procedure to verify repair.
- g. **Error Type 1793–1920:** System software received an indication that a socket was closed due to an error.

The Error Type indicates the application associated with this socket. The Aux Data value indicates the internal application number.

| Error Type | Application         |
|------------|---------------------|
| 1793       | Unused              |
| 1794       | DCS                 |
| 1795       | AUDIX               |
| 1796       | CMS                 |
| 1797       | ISDN Gateway        |
| 1798–1920  | Reserved for future |

- h. **Error Type 2305–2816:** System software detected a session is down. The Aux Data value indicates the session number. These are log-only errors. Error types 2305–2560 are for session numbers 1–256. Error types 2561–2816 are for session numbers 257–512.
- i. **Error Type 3329:** TCP/IP Ping test failed. A WARNING alarm is raised if the test fails twice. A MAJOR alarm is raised if the test fails 6 times.
  1. Test port (`test port location`).
  2. Refer to [TCP/IP Ping Test \(#1281\)](#) repair procedures.

---

## Demand test descriptions and error codes

Investigate errors in the order they appear in the following table.

| Order of Investigation                                 | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|--------------------------------------------------------|---------------------|--------------------|-------------------|
| <a href="#">Ethernet Local Looparound Test (#1278)</a> |                     | X                  | D                 |
| <a href="#">TCP/IP Ping Test (#1281)</a>               | X                   | X                  | ND                |
| <a href="#">Session Status Test (#1286)</a>            | X                   | X                  | ND                |
| <a href="#">Link Integrity Inquiry Test (#1282)</a>    | X                   | X                  | ND                |
| <a href="#">Verify NIC Options Test (#1511)</a>        | X                   | X                  | ND                |

1. D = Destructive, ND = Nondestructive

## ETR-PT (Enhanced Tone Receiver Port)

| MO Name in Log | Alarm Level       | Initial Command to Run          | Full Name of MO             |
|----------------|-------------------|---------------------------------|-----------------------------|
| ETR-PT         | MAJ<br>MIN<br>WRN | <code>test port location</code> | Enhanced Tone Receiver Port |

**Note:**

Replacing the Tone-Clock circuit pack requires a special procedure which is described in [TONE-BD \(Tone-Clock Circuit Pack\)](#). That section also describes the LED display for this board.

---

## TN2312AP IPSI Circuit Pack's Tone-Clock

For a PN with a TN2312 IPSI, the TONE-BD is a module located on the IPSI circuit pack. It provides tone generation, tone detection, call classification, and clock generation and synchronization. The TN2312 replaces the TN2182B Tone-Clock board and is inserted into each PN's Tone-Clock slot. For a non IPSI PN, the TN2182B Tone-Clock circuit packs provide the TONE-BD functions.

The TN2312 IPSI circuit pack (for PNs equipped with IPSIs) or the Tone-Clock circuit packs (for non IPSI PNs) both house two independent components:

- 1 Tone Generator that provides every tone needed by the system
- 1 Clock that generates clocks for both the system's Time Division Multiplex (TDM) bus and the LAN bus. It also aids in monitoring and selecting internal synchronization references.

When resolving errors/alarms on an IPSI or Tone-Clock circuit pack, the following sections should also be consulted:

- 1 For a non IPSI PN, use `set tone-clock uc` to establish the tone and synchronization resources for the system.
- 1 For an IPSI PN, use `set ipserver-interface uc` to establish the tone and synchronization resources for the system.
- 1 TONE-PT (Tone Generator)
- 1 TDM-CLK (TDM Bus Clock)
- 1 SYNC (Synchronization)
- 1 TONE-BD
- 1 PKT-INT (IPSI only)

---

## TN2182 Tone-Clock Circuit Pack (for Non IPSI Connected PNs)

A TN2182 is a combined Tone Generator/Tone Detector board. It provides eight Enhanced Tone receiver (ETR) ports. Each of these ports provides the functions previously found individually on DTMR-PTs, GPTD-PTs and CLAS-PTs ports. Each port on the TN2182 may be used for any tone-detection function that was previously done by TN748, TN420, or TN744 Tone Detection boards.

The TN2182 provides Mu-law or A-law tone-detection capability.

Since the TN2182 also provides Tone-Clock function, only one TN2182 circuit pack may reside in a PN (or two if your system is duplicated). If more tone-detection resources are needed, the additional resources must be provided by TN748, TN420, or TN744 circuit packs.

---

## Error log entries and recommended actions

**Table 106: ETR-PT Error Log Entries**

| Error Type  | Aux Data | Associated Test                          | Alarm Level | On/Off Board | Recommended Action     |
|-------------|----------|------------------------------------------|-------------|--------------|------------------------|
| 1 (a)       | any      | Test #43 Tone Detector Audit/Update Test | MAJ<br>MIN  | ON           | test port location r 2 |
| 18          |          | busyout port                             | WRN         | OFF          | release port location  |
| 257 (a) (b) | 17666    | Test #43 Tone Detector Audit/Update Test | MAJ<br>MIN  | ON           | test port location r 3 |
| 513 (a) (c) | any      | Test #43 Tone Detector Audit/Update Test | MAJ<br>MIN  | ON           | test port location r 3 |

Notes:

- a. **Error Type 1, 257, 513:** There are two possible alarm levels for this Error Type: major alarm and minor alarm. These alarm levels are dependent on the administered thresholds for TTR, CPTR, and CCTR. Each ETR port is capable of operating on any of these.

A major alarm is raised if the total number of ports capable of TTR, CPTR or CCTR detection currently in service is less than or equal to one-half of the administered TTR, CPTR, or CCTR threshold number. Otherwise, a minor alarm is raised. The threshold number of ports for service is administered with **change system-parameters maintenance**.

If a major or minor alarm occurs, follow this repair procedure.

1. Use **list configuration carrier** to get the board type and location. If the board is TN744, then do steps 2–4; if it is TN2182 or TN2312, do steps 5–12.

2. Reset the board with `busyout board location`, `reset board location`, and `release board location`. A reset is required to reload RAM associated with the TN744's DSPs. This will take all eight tone detector ports out of service for a few seconds. Only four of the eight would be out of service due to the alarm. (There are four tone detectors on each of the two DSPs.) Other than the unlikely potential of running out of tone detector resources in the switch, there is no other effect when the board is reset.
  3. Test the board (`test board location long`).
  4. If the test passes, terminate the repair process. If the test fails, replace the board.
  5. Check to see if the board is duplicated (`list cabinet` and `status port-network` on the affected PN).
  6. If the board is not duplicated, use `test tone location long` to resolve the error. The long test resets the board and is required to reload on-board RAM associated with the DSPs. The effect is that tone detectors are taken out of service momentarily and tones are removed from the TDM bus for about 10 seconds. This means no dial pulses or touch tones during this interval, which probably will not affect calls in progress but could cause a call origination to abort or cause a user to not get dial tone when going off-hook.
  7. If every test passes and the alarm does not resolve, retest (`test tone location long clear`).
  8. If the test passes, terminate the repair process. If it fails, replace the circuit pack at the customer's convenience.
  9. If the board is duplicated, switch to the standby side (`set tone/set ipserver-interface`).
  10. Test the alarmed board (`test tone location long`). This resets the board and is required to reload on-board RAM associated with the circuit pack's DSPs.
  11. If every test passes and the alarm does not resolve, retest with `test tone location long clear`.
  12. If the test passes, terminate the repair process. If it fails, replace the board.
- b. **Error Type 257:** The ETR-PT lost its translation. Testing the ETR-PT is sufficient to reload its translation. If testing the ETR port does not clear the error, the circuit pack containing the defective ETR port should be replaced at a time when it is convenient to remove a clock board from the system. Follow the procedures described in [TONE-BD \(Tone-Clock Circuit Pack\)](#) for replacing a Tone-Clock circuit pack.
- c. **Error Type 513:** This error indicates the (ETR-PT) Enhanced Tone Receiver is having problems detecting touch tones, call-progress tones, or MFC tones. If this Error Type is persistently logged, the circuit pack containing the defective ETR-PT should be replaced at a time it is convenient to remove a clock board from the system. Follow the procedures described in [TONE-BD \(Tone-Clock Circuit Pack\)](#) for replacing a Tone-Clock circuit pack.

---

## Demand tests descriptions and error codes

Investigate tests in the order presented. By clearing errors associated with the first test, errors generated from other tests may also be cleared. Click on the link to see the full description of the test, error codes, and recommended actions.

| <b>Order of Investigation</b>                          | <b>Short Test Sequence</b> | <b>Long Test Sequence</b> | <b>D/ND<sup>1</sup></b> |

## EXP-INTF (Expansion Interface Circuit Pack)

| MO Name in Log | Alarm Level       | Initial Command to Run           | Full Name of MO                  |
|----------------|-------------------|----------------------------------|----------------------------------|
| EXP-INTF       | MAJ<br>MIN<br>WRN | <code>test board location</code> | Expansion Interface circuit pack |

If the Expansion Interface (EI) circuit pack that is being investigated is associated with a Survivable Remote EPN (SREPN), every LAPD EI link problem must be cleared, and the SREPN slide switch on the TN2301 (located in the SREPN carrier) must be manually set to the normal position before the SREPN can be returned to normal service. See [Restoring Normal Service to the SREPN](#).

Refer also to *Avaya MultiVantage Solutions Installation and Maintenance for Survivable Remote EPN*.

Following this introductory description of the Expansion Interface (EI) circuit pack are sections on the following topics:

- 1 [EI In-Service Mechanism](#)
- 1 [Survivable Remote EPN](#)
- 1 [LEDs](#)
- 1 [EI and Tone-Clock Interactions](#)
- 1 [Replacing an EI Circuit Pack—Unduplicated PNC](#)
- 1 [Replacing an EI Circuit Pack— Duplicated PNC](#)
- 1 [Expansion Interface Manual Loopback Procedure](#)

The TN570 or the TN776 Expansion Interface (EI) circuit pack provides a TDM- and packet bus-to-fiber interface for the communication of signaling information, circuit-switched connections, and packet-switched connections between endpoints residing in separate PNs. EI circuit packs are connected via optical fiber links. An EI can be connected to:

- 1 Another EI, in a direct-connect configuration
- 1 A DS1 converter in a DS1 converter complex, used to remote a PN
- 1 A Switch Node Interface (SNI), in a center stage switch (CSS) configuration
- 1 A survivable remote EPN (SREPN)

In a CSS configuration with duplicated Port Network Connectivity (PNC), EI circuit packs reside in the Switch Node Carrier (see [Figure 28: Center Stage Switch Configuration with Duplicated PNC](#)). In this case, the EI and SNI circuit packs may be connected via a metallic cable instead of an optical fiber link. Metallic cable should be tested and replaced in the same mer as optical fiber.

A PN-to-PN connection can be extended through a DS1 converter complex. (See [Figure 29: Fiber Link with DS1 Converter Complex](#)). When discussing problems that may be related to fiber links, the DS1 converter is considered part of the fiber link. If diagnosis of the problem points to fiber connectivity and a DS1 converter circuit pack is part of the connectivity, problems with the DS1 converter circuit pack should be investigated (see [DS1C-BD \(DS1 Converter Circuit Pack\)](#)). The DS1 converter circuit pack runs diagnostics for the EI circuit pack via such tests as the [Expansion Interface Neighbor Query Test \(#237\)](#), the [Expansion Interface Fiber Out-of-Frame Query Test \(#238\)](#), the [Expansion Interface 2-Way Transmission Test \(#241\)](#), and the [Expansion Interface Packet Interface Test \(#589\)](#).

In a critical-reliability system, the fiber link's are duplicated as part of PNC duplication. In a high-reliability system with a CSS (Center Stage Switch) and unduplicated PNC, a single point of failure between the server and the CSS is eliminated by duplicating each link, consisting of:

- 1 SNI in the CSS to which the PN's EI connects
- 1 Physical fiber paths between them

These dual connections normally share the call-processing load. Should one of these links fail, the entire load can be shifted to the operational link.

[Figure 25: Direct Connect Configuration with Unduplicated PNC](#) shows the location of the EI circuit packs in a typical unduplicated PNC, direct connect configuration.

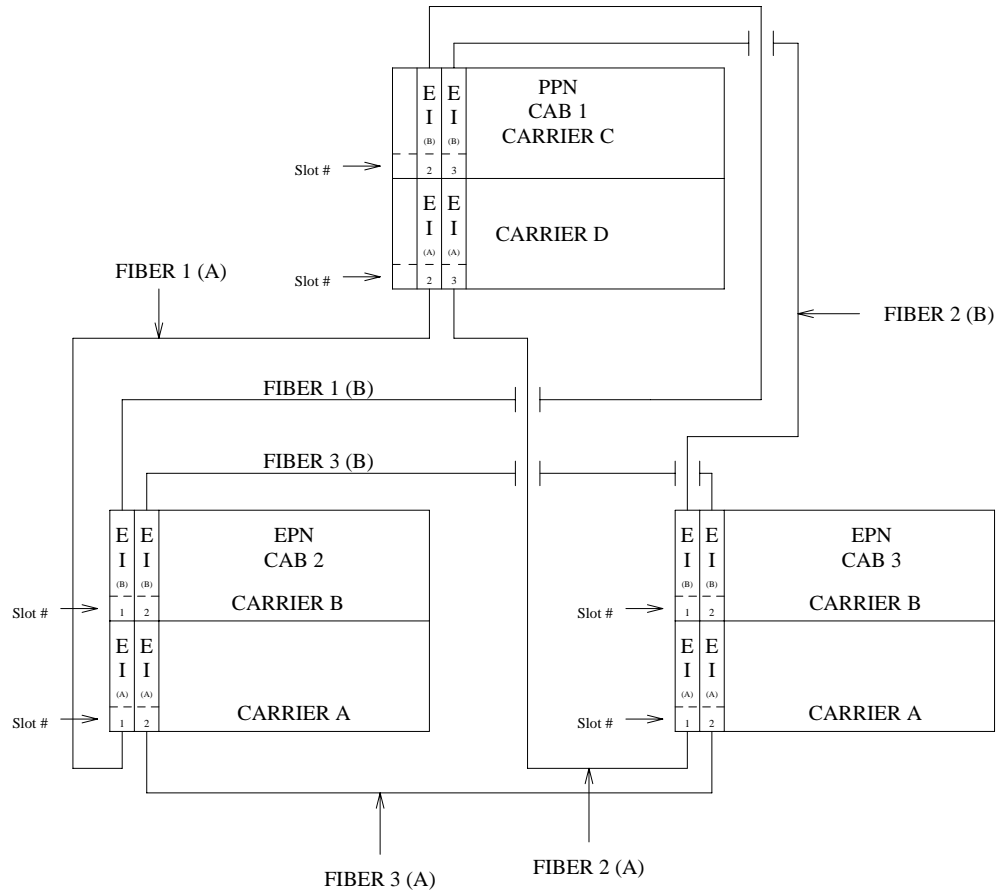

**Figure 25: Direct Connect Configuration with Unduplicated PNC**

Each PN in a direct-connect configuration must be connected to the other PNs through a fiber link. Each PN has one EI that functions as an Archangel. This EI must be connected with fiber to an EI. If an EI is functioning as an Archangel (bus master), its amber LED will be flashing at a rate of 2 seconds on and 200 ms off.

Figure 26: [Direct Connect Configuration with Duplicated PNC](#) shows the location of EI circuit packs in a typical duplicated PNC, direct-connect configuration.

Figure 26: Direct Connect Configuration with Duplicated PNC

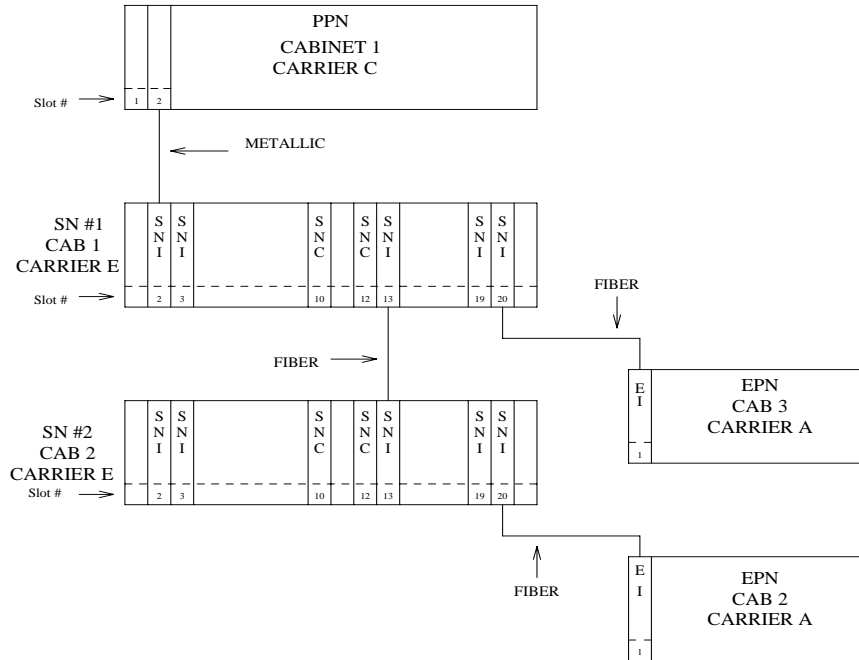

In a duplicated PNC there is an A-side and a B-side PNC. Every EI in this diagram is labeled with an A or a B designating to which PNC it belongs. Note that a PNC's designation (A or B) does not relate directly to the carrier where its EIS reside. Again, only one of a PN's EIs can function as the Archangel (TDM-bus master). A PN's EI that is:

- 1 On the active PNC
- 1 Logically connected to the server

is the only one that can function in this mode. In normal operation, its amber LED should be blinking at a rate of 2 seconds on and 200 ms off.

Figure 27: [Center Stage Switch Configuration with Unduplicated PNC](#) shows the location of EIs in a typical center stage switch configuration with unduplicated PNC.

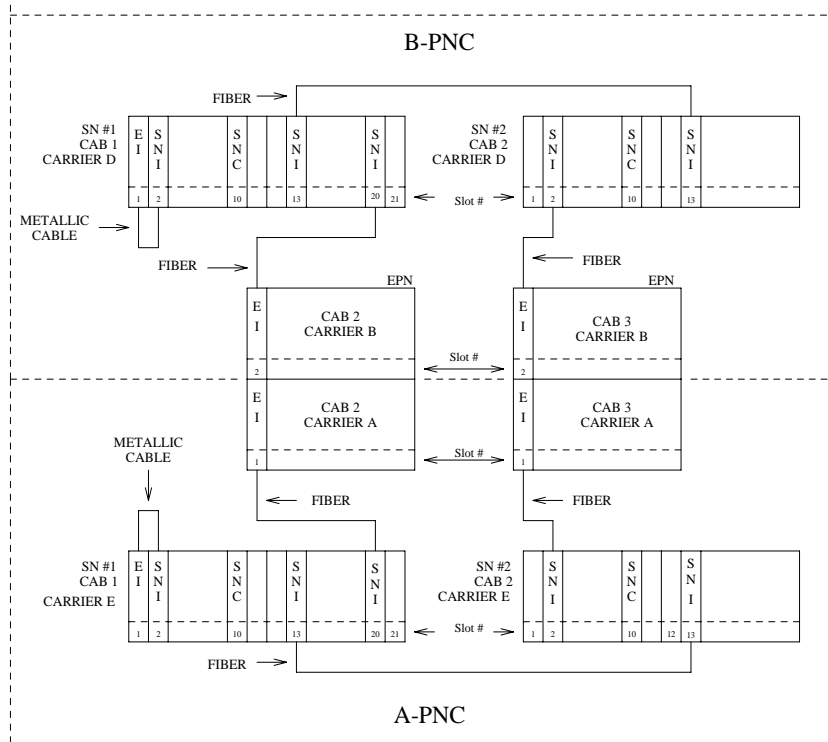

**Figure 27: Center Stage Switch Configuration with Unduplicated PNC**

For an unduplicated center stage switch configuration, only one EI is needed in each PN. Notice that there is no direct connection between the PNs, rather every inter-PN connection is made through the center stage switch. Each SNI in the switch node carriers can be connected to a PN through an EI circuit pack.

[Figure 28: Center Stage Switch Configuration with Duplicated PNC](#) shows the location of EIs in a typical two Switch Node Center Stage Switch configuration with duplicated PNC.

Figure 28: Center Stage Switch Configuration with Duplicated PNC

In a duplicated center stage switch configuration, two EIs are needed in each PN. One resides in the PNC's A side and one in the B side. Note that a PNC designation (A or B) does not directly designate the carrier where an EI resides. The active PNC's EI is the one acting as the PN's Archangel (TDM bus master). This EI's amber LED should be blinking at a rate of 2 seconds on and 200 ms off. Whereas, the amber LED on standby PNC's EI should be off.

A PN (and thus, the EIs contained within it) can be remoted via a DS1 Converter complex. This requires that a fiber link (providing connectivity to the remoted PN) be administered with an associated DS1 Converter complex. This complex consists of two TN574 DS1 Converter (DS1C-BD) circuit packs connected by from 1 to 4 DS1 facilities. [Figure 29: Fiber Link with DS1 Converter Complex](#) shows where the DS1 converter complex fits into an EI-to-SNI or EI-to-EI fiber link. For more information, see [DS1C-BD \(DS1 Converter Circuit Pack\)](#).

---

**Figure 29: Fiber Link with DS1 Converter Complex**

---

## EI In-Service Mechanism

In order for calls to be routed through a given PN, the EI that is part of the connectivity to that PN must be put into service. In order for an EI to be put into service, the following criteria must be met:

1. The EI must be recognized by software (inserted). Use `list config carrier` to verify that the board is recognized by software.
2. The EI must have a fiber link administered to it. Use `list fiber-link` to verify that this EI circuit pack has a fiber administered to it.
3. The EI must have established a LAPD link to its neighbor (the circuit pack on the “other end” of the fiber link). This neighbor can be another EI or an SNI.

**! CAUTION:**

If previous requirements 1 and 2 have been met, and the amber LEDs are flashing in a mer that appears to confirm that the EI circuit pack has established a LAPD link to its neighbor, the circuit pack still may not be “in service”. The requirement is that it must have the CORRECT neighbor on the other end of the fiber. Care must be taken when connecting the fibers to the back of the carriers so that fibers are connected to the correct circuit packs. In a Center Stage Switch configuration, run the “configuration audit” test against the SNI circuit pack that is the neighbor of the EI circuit pack in question (see [SNI-BD \(SNI Circuit Pack\)](#) for more details).

Once an EI has been put into service, if any of the previously listed in-service criteria become untrue, the EI is taken out of service, and service to that PN is not available.

In a system that is configured with PNC duplication active, taking an EI out of service that is on the active PNC will, if all other things on the active and standby PNC are equal (i.e., both PNCs are equally healthy, the standby PNC is not busied out, the PNC is not locked by software), result in a PNC interchange.

---

## Survivable Remote EPN

**Note:**

This feature is viewed as a “disaster recovery operation” capability rather than as an additional reliability option.

The SREPN allows a remote EPN cabinet to provide processor capabilities to the EPN in the event of a failure. A logic switch circuit pack (TN2301) located in the SRPPN detects when the link to the server is down and switches to a link from the local SRPPN (TN790B-based processor). When the links to the server are restored and verified to be stable, the logic switch is manually reset, and the EPN is reconnected to the links from the server.

**Note:**

The SREPN feature is not available when an ATM-PNC/EI circuit pack is used to replace the TN570 EI circuit pack in a direct-connect configuration, or an ATM Switch is providing the Center Stage (PNC) connectivity.

## SREPN Feature Active

Every call within the SREPN is terminated when the SREPN feature is activated, and the SRPPN takes control of the SREPN.

The SREPN feature is activated when the Maintenance circuit pack (TN775C or later and located in the SREPN) detects a problem with the SREPN's EI (TN570B) LAPD link to its counterpart in an EPN. The TN775C Maintenance circuit pack notifies the co-located SRPPN of the problem, and the TN2301 / circuit pack in the SRPPN carrier switches the EI LAPD link connection from the Port Network to its counterpart in the SRPPN. The SREPN is now in the Survivable Remote mode and has the capabilities of an EPN that has been pre-translated with a *Disaster Recovery* configuration.

**Note:**

When the SREPN feature is active, the EI circuit pack that is assigned to the SREPN and located in the PN is put in loopback mode.

## Restoring Normal Service to the SREPN

Every call within the SREPN is terminated when the SREPN feature is returned to normal service.

To restore normal connections to the SREPN EI circuit pack in the PN, you must:

1. Clear every error logged against the SREPN EI circuit pack by using the suggested repair procedures outlined in this MO.
2. At the SRP flip the 3-position switch on the TN2301 to the RSTR (restore) or top position for at least 1 second and return the switch to the AUTO, or middle position.

3. After the SREPN slide switch has been restored to the normal position, test the connectivity to EI LAPD link, by using the suggested procedures outlined in this MO.
4. After normal service is returned to the SREPN, the SRPPN will be in an *alarmed state*. This is *normal* for an SRPPN and indicates that the:
  1. SRSwitch (TN2301) has disconnected it from its neighbor (EI in the SREPN)
  1. SRPPN is no longer in control.

Connectivity has been re-established between the EI in the SREPN and its counterpart EI circuit pack in the PN. The system is now in a normal EI configuration.

## LEDs

### SREPN Expansion Interface

The EI circuit pack has red, green, and amber LEDs. The red and green LEDs display the standard conditions:

- 1. Red indicates an alarm condition.
- 1. Green indicates maintenance testing in progress.

The amber LED provides useful visual status information:

- 1. Active EI circuit packs:
  - Have their amber LED on solid (for an inter-EPN EI in a direct connect system)
  - Blink a pattern of 2 seconds on and 200 ms off.
- 1. The standby PNC EI circuit packs should have their amber LEDs off.

Another way to determine which PNC (and therefore, which EIs in an EPN) is active and which is standby, use `status port-network` and `status PNC`.

See [Table 107: Expansion Interface Circuit Pack Amber LED Flashing States](#) for the possible EI amber LED states.

**Table 107: Expansion Interface Circuit Pack Amber LED Flashing States 1 of 2**

| Condition                      | LED On     | LED Off    |
|--------------------------------|------------|------------|
| Fiber Out-of-Frame (a)         | 0.1 second | 0.1 second |
| In Frame-No Neighbor (b)       | 0.5 second | 0.5 second |
| Expansion Interface Active (c) | 2 second   | 0.2 second |
| Expansion Interface Active (d) | solid on   | never off  |
| <b>1 of 2</b>                  |            |            |

**Table 107: Expansion Interface Circuit Pack Amber LED Flashing States 2 of 2**

| Condition                       | LED On   | LED Off   |
|---------------------------------|----------|-----------|
| Expansion Interface Standby (e) | never on | solid off |
| <i>2 of 2</i>                   |          |           |

## Notes:

- a. This flashing state corresponds to error codes 769 and 770 from the Hardware Error Log and indicates a failure of Test #238. These error codes are usually accompanied by error code 1281 (no EI or SNI detected on opposite end of fiber). This condition may be caused by the absence of the neighbor EI or SNI circuit pack, a broken or missing fiber, or a missing lightwave transceiver on either endpoint (EI or SNI circuit packs).
- b. This corresponds to error code 1281 from the Hardware Error Log and indicates a failure of [Expansion Interface Neighbor Query Test \(#237\)](#). This condition is usually due to the failure of this EI circuit pack or a failed EIEI or SNI circuit pack counterpart.
- c. This is the normal state for an active PN EI circuit pack that is also the bus master (Expansion Archangel) in the EPN.
- d. This is the normal state for an active EI circuit pack that is not the bus master (Expansion Archangel) for a PN. This applies only in the direct-connect configuration where the EI circuit pack in a PN is connected via a fiber link to an EI circuit pack in the other PN.
- e. This is the normal state for a standby EI circuit pack in a PN.

**Note:**

In a PN, its TN775C Maintenance (MAINT) circuit pack monitors the sanity of the EI circuit pack. If the EI circuit pack should cycle between sane and insane several times, the Maintenance circuit pack will hold the EI circuit pack reset. If a new EI circuit pack is installed in the PN, and the red LED remains lit, the PN's Maintenance circuit pack should be removed because it may be holding the new EI circuit pack reset. This condition could present itself if there is a link problem to the PN, and the PN experiences several PN restarts. The Maintenance circuit pack may be reinstalled after the EI circuit pack has been physically inserted and the EI circuit pack's red LED has gone off.

The link between two active EI circuit packs or between an active EI circuit pack and an active SNI circuit pack is involved in synchronization. The EI circuit pack reports slip errors if synchronization is not operating properly. When diagnosing synchronization problems, the EI circuit packs should be examined as a possible cause.

## Expansion Interface LEDs

The EI circuit pack has the standard red, green, and amber LEDs. The red and green LEDs have the traditional uses: red means some alarm condition and green indicates maintenance testing in progress. The amber LED provides useful visual status information. The state of the amber LED is very important when executing the [Expansion Interface Manual Loopback Procedure](#). The possible amber LED states are shown in [Table 108: Expansion Interface Circuit Pack Amber LED Flashing States](#).

Upon power-up, the red and green LEDs turn on and off. The amber LED goes to its appropriate state.

To determine which PNC (and which EIs in a PN) is active and which is standby, use `status port-network` and `status pnc`. Alternately, visual inspection will show that the active EI circuit packs will have their amber LED on solid (for an inter-PN EI in a direct connect system) or blink a pattern of 2 seconds on and 200 ms off. The standby PNC EI circuit packs will have their amber LEDs off. See [Table 108: Expansion Interface Circuit Pack Amber LED Flashing States](#) for the possible EI amber LED states.

**Table 108: Expansion Interface Circuit Pack Amber LED Flashing States**

| Condition                       | LED On     | LED Off    |
|---------------------------------|------------|------------|
| Fiber Out-of-Frame (a)          | 0.1 second | 0.1 second |
| In frame-No Neighbor (b)        | 0.5 second | 0.5 second |
| Expansion Interface Active (c)  | 2 second   | 0.2 second |
| Expansion Interface Active (d)  | solid on   | never off  |
| Expansion Interface Standby (e) | never on   | solid off  |

### Notes:

- a. Fiber Out-of-Frame - This flashing state corresponds to error codes 769 and 770 from the Hardware Error Log and indicates a failure of Test #238. These error codes will usually be accompanied by error code 1281 (no Expansion Interface or SNI detected on opposite end of fiber). This condition may be caused by the absence of the neighbor EI or SNI circuit pack, a broken or missing fiber, or a missing lightwave transceiver on either endpoint (EI or SNI circuit pack).
- b. In frame-No Neighbor - This flashing state corresponds to error code 1281 from the Hardware Error Log and indicates a failure of [Expansion Interface Neighbor Query Test \(#237\)](#). This condition is usually due to the failure of this EI circuit pack or a failed EI or SNI circuit pack neighbor.
- c. This is the normal state for an active PN EI circuit pack that is also the bus master (Expansion Archangel) in the PN.

- d. This is the normal state for an active EI circuit pack that is not the bus master (Expansion Archangel) for a PN. This applies only in the Direct Connect configuration where the EI circuit pack in a PN is connected via a fiber link to an EI circuit pack in the other PN.
- e. This is the normal state for a standby EI circuit pack in a PN.

**Note:**

In a PN, its TN775C Maintenance (MAINT) circuit pack monitors the sanity of the EI circuit pack. If the EI circuit pack should cycle between sane and insane several times, the Maintenance circuit pack will hold the EI circuit pack reset. If a new EI circuit pack is installed in the PN, and the red LED remains lit, the PN's Maintenance circuit pack should be removed because it may be holding the new EI circuit pack reset. This condition could present itself if there is a link problem to the PN, and the PN experiences several PN restarts. The Maintenance circuit pack may be reinstalled after the EI circuit pack has been physically inserted and the EI circuit pack's red LED has gone off.

The link between two active EI circuit packs or between an active EI circuit pack and an active SNI circuit pack is involved in synchronization. The EI circuit pack will report slip errors if synchronization is not operating properly. When diagnosing synchronization problems, the EI circuit packs should be examined as a possible cause.

---

## EI and Tone-Clock Interactions

The viability of the EI fiber link depends upon the system clock that is provided by the active Tone-Clock circuit pack on each network (see [TDM-CLK \(TDM Bus Clock\)](#) and [TONE-BD \(Tone-Clock Circuit Pack\)](#)). Each EI circuit pack transmits over the fiber at a rate derived from the system clock on its network. If the active Tone-Clock is defective in such a way that the frequency of system clock it produces is out of the specified range ("out of spec"), an EI fiber link might go down. This affects an Expansion Archangel Link (EAL), a Remote Neighbor Link (RNL), and/or a Local Neighbor Link (LNL), even though the EI circuit packs are healthy. When the PNC is duplicated, both fiber links could go down if there is a defective active Tone-Clock.

Whether or not a fiber link goes down, depends on certain characteristics of the EI circuit packs. An EI circuit pack should not be replaced if the fiber link on which it resides goes down because of a defective active Tone-Clock circuit pack. The defective Tone-Clock circuit pack should be replaced instead. The EI circuit packs are more sensitive to a defective system clock than the rest of the components of the system. Therefore, testing of the Tone-Clock circuit pack might not reveal a problem.

The symptoms of the problem in which an invalid system clock causes an Expansion Link to go down are as follows:

1. If the Tone-Clock in the PN provides the current on-line synchronization reference (see **status synchronization**), is providing an invalid system clock:

Any EI or SNI circuit pack has a Fiber Out-of-Frame condition or a No Neighbor condition.

An EI circuit pack amber LED blinks quickly when a Fiber Out-of-Frame condition exists (0.1 seconds on, 0.1 seconds off) and the [Expansion Interface Fiber Out-of-Frame Query Test \(#238\)](#) fails on the EI circuit pack that is out-of-frame.

An SNI circuit pack with a Fiber Out-of-Frame condition blinks its amber LED quickly (0.1 seconds on, 0.1 seconds off) and Test #989 fails on the SNI circuit pack that is out-of-frame.

An EI circuit pack amber LED blinks slowly when a No Neighbor condition exists (0.5 seconds on, 0.5 seconds off) and the [Expansion Interface Neighbor Query Test \(#237\)](#) fails on this EI circuit pack, but Test #238 passes.

An SNI circuit pack with a no neighbor condition blinks its amber LED slowly (0.5 seconds on, 0.5 seconds off) and [Configuration Audit \(#759\)](#) fails on this SNI circuit pack, but Test #989 passes.

1. If a Tone-Clock in a PN that does not provide the current on-line synchronization reference (see **status synchronization**) is providing an invalid system clock:

*In a direct connect configuration*, the PN EI circuit pack amber LED will blink quickly (Fiber Out-of-Frame condition – 0.1 seconds on, 0.1 seconds off).

[Expansion Interface Fiber Out-of-Frame Query Test \(#238\)](#) fails on this EI circuit pack.

*In a CSS configuration*, the SNI connected to the PN EI circuit pack blinks its amber LED quickly (Fiber Out-of-Frame condition – 0.1 seconds on, 0.1 seconds off).

The PN EI circuit pack amber LED blinks slowly (In-frame, No Neighbor condition – 0.5 seconds on, 0.5 seconds off).

If the PN is in service, [Expansion Interface Neighbor Query Test \(#237\)](#) fails on this EI circuit pack, but Test #238 passes.

These symptoms can also be the result of other problems (for example, one half of the fiber being unable to transmit data). If the system exhibits these symptoms, execute the following procedure:

1. Verify that the PN stays down for at least 1 minute.

If the EAL comes back in service after a short time, without switching the active Tone-Clock, the problem was probably that the on-line synchronization source became invalid. See [SYNC \(Port Network Synchronization\)](#) for more information.

However, if the EAL(s) have not come back into service after a minute, the synchronization source is not the cause of the problem. Proceed to step 2.

2. Check for errors via **display errors** with the `Category` field set to **tone** and the Active Alarms field set to **n**. Some of the alarms on PN objects might have been resolved if the PN went down. Refer to the appropriate MO Maintenance documentation for descriptions of any of the errors occurring at about the same time as the EXP-PN errors, SYS-LINK errors against EALs, RNLs, or LNLs, or FIBER-LK (769, 1025, or 1281) errors. Resolve any active alarms. Also, if Error Type 18 was logged against the SYNC MO when the PN went down, the problem was probably that the synchronization on-line reference became invalid. Since reference switching was disabled, the Tone-Clock did not switch from the invalid reference. Therefore, the Tone-Clock circuit pack put out a system clock that was "out of spec." Enter **enable synchronization-switch**. If the PN is down, reseal the Tone-Clock circuit packs on the PN. This action should restore the PN to service.

Execute Steps 3 and 4 in the order most convenient to you and least destructive to the customer.

3. Check to see if the fiber-optic cable is transmitting properly via the following procedure on one of the out-of-service links, or use the [Fiber link fault isolation](#) in *Maintenance Procedures (03-300432)*.
  - a. Carefully record the symptoms (amber LED pattern and test failing) that were occurring on the PN EI circuit pack and the PN EI circuit pack or the connected CI circuit pack in the case of a Center Stage system. Clearly indicate what symptoms are occurring on which EI/SNI circuit pack.

 **CAUTION:**

Before proceeding, note which is the current transmit fiber and which is the current receive fiber for proper re-connection.

- b. Disconnect the transmit and receive fiber pair from the lightwave transceiver on the back of one of the EI circuit pack slots that is exhibiting symptoms.
  - c. Connect what was formerly the transmit fiber to the receive jack.
  - d. Connect what was formerly the receive fiber to the transmit jack.
  - e. Perform steps b, c, and d on the opposite end of the fiber and the lightwave transceiver on the back of the connected EI or SNI circuit pack slot.
  - f. If the symptoms that were formerly occurring on the EI circuit pack that was exhibiting these symptoms are now occurring on the connected EI or SNI circuit pack and vice versa, the fiber is defective and should be replaced.
4. Determine whether the problem is due to a defective active Tone-Clock circuit pack. Refer to the preceding list of symptoms to decide which network contains the suspect active Tone-Clock.

 **CAUTION:**

If you remove the PN EI circuit pack that is active or that was active when the PN was last in service, the Tone-Clock lead will revert to the default value which will cause the Tone-Clock circuit pack located in the A carrier to become the active Tone-Clock. This characteristic can be deceiving. Replacing or reseating the active PN EI circuit pack might restore the link(s) temporarily. However, if the Tone-Clock circuit pack located in the B carrier was really the source of the problem and not the EI circuit pack, then the link(s) will go down again the next time a Tone-Clock switch to the Tone-Clock in the B carrier is attempted (probably when the scheduled Tone-Clock switch occurs).

 **CAUTION:**

If, after every link is restored, you suspect the problem might have been due to a defective Tone-Clock circuit pack, switch to this Tone-Clock at an appropriate time. If the Tone-Clock circuit pack was the cause of the problem and the same EI circuit packs are in place, the same link(s) will go down again.

- a. When the suspect Tone-Clock circuit pack resides in an in-service pot network (PN) with duplicated Tone-Clock circuit packs:

Switch to the standby Tone-Clock in this PN. If the suspect Tone-Clock is defective, the link(s) should be restored at this point. (Switching back to the defective Tone-Clock should take the same link(s) out of service.) This Tone-Clock is defective and should be replaced as soon as possible. If switching Tone-Clocks does not bring up the PN, then this Tone-Clock is not the source of the problem. Be sure to switch back to the original Tone-Clock.

 **CAUTION:**

If a defective Tone-Clock circuit pack is left as the standby Tone-Clock, then a scheduled Tone-Clock switch will cause the same link(s) go out of service again.

- b. When the suspect Tone-Clock resides in an out-of-service PN:

Replace the active Tone-Clock circuit pack in this PN. In a PN with duplicated Tone-Clock circuit packs, the active Tone-Clock's amber LED is flashing. If both amber LEDs are flashing, the active Tone-Clock's LED is blinking slower.

 **CAUTION:**

If a defective Tone-Clock circuit pack is left as the standby Tone-Clock, then a scheduled Tone-Clock switch will cause the same PN to go out of service again.

If replacing this circuit pack restores the link(s), then the circuit pack should be replaced as soon as possible. If not, then it was not the source of the problem.

## Replacing an EI Circuit Pack—Unduplicated PNC

Do not power down a Switch Node carrier to replace a circuit pack.

Replacing a Switch Node Interface, Switch Node Clock, Expansion Interface, or DS1 Converter circuit pack in a standard-, duplex-, or high-reliability system disrupts service. This service effect can range from an outage of a single PN to an outage of the entire system.

| Step | Action                                                                                                                  | Explanation / Caution                                                                                                                        |
|------|-------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------|
| 1.   | Enter <code>busyout board location</code> .                                                                             | location = cabinet-carrier-slot location of the circuit pack to be replaced.                                                                 |
| 2.   | Replace the circuit pack.                                                                                               |                                                                                                                                              |
| 3.   | Wait for the circuit pack to reset.                                                                                     | Red and green LEDs light and then go out. If the red LED remains lit, see the previous note under <a href="#">Expansion Interface LEDs</a> . |
| 4.   | Enter <code>release board location</code> .                                                                             | CAUTION: Do not busyout any EI circuit packs after this point.                                                                               |
| 5.   | Enter <code>test alarms long clear</code> for category <code>exp-intf</code> .                                          |                                                                                                                                              |
| 6.   | Wait 5 minutes for SNI-BD, FIBER-LK, and DS1C-BD alarms to clear, or enter <code>clear firmware-counters a-pnc</code> . |                                                                                                                                              |

## Replacing an EI Circuit Pack— Duplicated PNC

On a system with duplicated PNC, synchronization may be provided over a combination of active and standby components. This condition is indicated by an OFF-BOARD WARNING alarm against TDM-CLK with Error Type 2305. Repairs to standby PNC in this state may disrupt service. Otherwise, if the active PNC is functional, replacement of a standby component will not disrupt service.

| Step          | Action                          | Explanation / Caution                                           |
|---------------|---------------------------------|-----------------------------------------------------------------|
| 1.            | Enter <code>status pnc</code> . | Verify that the component to be replaced is on the standby PNC. |
| <b>1 of 2</b> |                                 |                                                                 |

| Step          | Action                                                                                                                                                  | Explanation / Caution                                                                                          |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------|
| 2.            | Enter <code>busyout pnc</code> .                                                                                                                        |                                                                                                                |
| 3.            | Enter <code>busyout board location</code> .                                                                                                             | location represents the cabinet-carrier-slot location of the circuit pack to be replaced.                      |
| 4.            | Replace the circuit pack.                                                                                                                               |                                                                                                                |
| 5.            | Enter <code>release board location</code> .                                                                                                             | CAUTION: Do not busyout any EI circuit packs after this point.                                                 |
| 6.            | Enter <code>test alarms long clear</code> for category <code>exp-intf</code> .                                                                          |                                                                                                                |
| 7.            | Wait 5 minutes for SNI-BD, SNI-PEER, FIBER-LK, and DS1C-BD alarms to clear, or enter <code>clear firmware-counters a-pnc</code> or <code>b-pnc</code> . | Use the letter designation of the PNC that holds the replaced component (the standby PNC).                     |
| 8.            | Enter <code>status pnc</code> .                                                                                                                         | If either PNC's state of health (SOH) is not "functional," consult <a href="#">PNC-DUP (PNC Duplication)</a> . |
| 9.            | Enter <code>release pnc</code> .                                                                                                                        |                                                                                                                |
| <b>2 of 2</b> |                                                                                                                                                         |                                                                                                                |

If the red LED remains lit, see the previous note under [Expansion Interface LEDs](#).

---

## Expansion Interface Manual Loopback Procedure

This procedure is to be used when an EI circuit pack cot be tested by software. This occurs when the EI circuit pack resides in an out-of-service PN. A short length of optical fiber is required for this procedure.

If this procedure is run on both endpoints of a fiber link (EI circuit packs or SNI circuit packs), and both check out fine, then the failure is most likely in the fiber itself, assuming neither endpoint circuit pack is busied out and the link remains inactive.

1. Busyout the circuit pack (EI or SNI) with `busyout board location`.
2. Disconnect the transmit and receive fiber pair from the lightwave transceiver on the back of the circuit pack (EI or SNI) slot.

**Note:**

The fiber connected to the transmit side of the lightwave transceiver on one EI circuit pack should be connected to the receive side of the lightwave transceiver on the circuit pack on the opposite end of the fiber.

3. Using a fiber jumper cable, interconnect the transmit and receive jacks of the lightwave transceiver as shown in [Figure 30: Interconnection of Lightwave Transceiver Transmit/Receive Jacks](#).

**Note:**

Make sure that the total length of the fiber jumper cable does not exceed the maximum length recommended for the fiber link connections between cabinets. Using cable lengths not within connectivity guidelines can adversely affect test results.

4. Go to the front of the cabinet and inspect the amber LED.
  - 1 If the amber LED flashes on at a rate of once per second, the (EI or SNI) circuit pack or transceiver should be replaced.
  - 1 If the amber LED flashes on at a rate of five times per second, the circuit pack (EI or SNI) or the lightwave transceiver may need replacement. This condition may also be due to a faulty system clock on the network containing this EI circuit pack.
  - 1 If the amber LED is not blinking, this circuit pack (EI or SNI) and the lightwave transceiver are functioning properly.
5. Replace faulty components and reconnect the original fiber. Be sure to reconnect the fibers properly as noted in step 3. If there is a problem with the PN after re-connecting the fiber, and the PN is connected to a Center Stage Switch, run the Configuration Audit via **test board** on the SNI circuit pack to which the intervening fiber is connected. See the SNI-BD section for instructions on interpreting results.
6. Release EI circuit pack or SNI circuit pack with **release board location**.

**Figure 30: Interconnection of Lightwave Transceiver Transmit/Receive Jacks**

| 3842(u,v)  | Any                   |                                 | MIN         | OFF          | (s)                     |
| 10001 (w)  | 0                     |                                 |             |              |                         |
|            |                       |                                 |             |              | <b>3 of 3</b>           |

1. Aux Data 32767 for any error log entry indicates that an alarmed EI was busied out and then released. When this occurs, existing service affecting alarms must be preserved. As is typical, when the EI is released every alarm is resolved. Therefore the alarm and error logs must be repopulated with the alarms present at time of busyout. This error code is an indication that existing aux data and error log time stamps are no longer valid because they were lost when the alarms were resolved upon release of the circuit pack.
2. Run the short test sequence first. If every test passes, run the long test sequence. Refer to each appropriate test's description, and follow its recommended procedures.

Notes:

- a. **Error Type 18:** the EI circuit pack has been busied out via **busyout board location**. To resolve this error, release the EI circuit pack via **release board location**.
- b. **Error Type 23:** the EI circuit pack has been administered on the Circuit Pack screen, but has not been physically inserted into the system. Insert the circuit pack.
- c. **Error Type 125:** A different circuit pack occupies the slot where this circuit pack is logically administered. To resolve this problem, either:
  1. Replace the incorrect circuit pack with the logically assigned circuit pack.

2. Use `change circuit-pack` to reassign the slot to match the existing circuit pack. If a fiber is assigned for the existing circuit pack, remove the fiber from translations before changing the circuit pack's translations.
- d. **Error Type 131:** an EI circuit pack has been removed from a slot for 5 minutes. The alarm will be resolved when the EI circuit pack is physically inserted into this slot and becomes recognized by software.
- Another way to resolve this alarm is to use `change circuit pack` to remove the EI circuit pack administrative entry for this slot after the EI circuit pack has been removed from the slot.
- It is also possible that the EI could be held in reset by the PN's Maintenance board (MAINT) and is not inserted in the system. Enter `test maint P long` on the Maintenance board in the same PN.
- e. **Error Type 257:** this EI circuit pack is detecting incorrect data on the incoming fiber bit stream. The data is originating at the connected circuit pack (DS1 converter circuit pack, EI circuit pack, or SNI circuit pack).
1. Enter `display errors` and save a copy of the error log for use in later steps. Intervening repair procedures are likely to alter the contents of the error log and this information may be needed in later steps.
  2. Perform the [Fiber link fault isolation](#) procedures described in *Maintenance Procedures (03-300432)*.
  3. If errors are still present or if this error occurs intermittently, replace the EI circuit packs, SNI circuit packs, DS1 converter circuit packs, or the transceivers on this link.
  4. These errors could result from a bad timing reference on the network or switch node that contains the DS1 converter, EI, or SNI circuit pack on the opposite end of the fiber. Refer to the error log that was saved in step 1 and follow the associated repair procedure for [EXP-INTF \(Expansion Interface Circuit Pack\)](#) error 2305 to resolve this error. If there are any [TONE-BD \(Tone-Clock Circuit Pack\)](#), [TDM-CLK \(TDM Bus Clock\)](#), or [SYNC \(Port Network Synchronization\)](#) errors, resolve these errors as well.
- f. **Error Type 513 with Aux Data 5–7:** an ON BOARD hardware failure of the circuit pack's RAM or ROM. Replace the EI circuit pack.
- g. **Error Type 769:** Besides running the test sequence and following procedures outlined for [Expansion Interface Fiber Out-of-Frame Query Test \(#238\)](#), perform the [Fiber link fault isolation](#) procedures described in *Maintenance Procedures (03-300432)*.
- h. **Error type 1281:** The link to the neighbor circuit pack is broken or the fibers have been connected incorrectly. Enter `test board location` and follow repair procedures for the tests.
- i. **Error Type 1538:** a hyperactive EI circuit pack is generating an abnormal amount of control messages to the Processor. When this error was generated, the EI was automatically reset by the system. If this system does not have duplicated Port Network Connectivity, service to the PN will have been disrupted. If this system does have duplicated Port Network Connectivity, the system should have switched to the standby Port Network Connectivity.

1. Enter `reset board location` for this EI circuit pack.
  2. If error 1538 is detected again, replace the EI circuit pack.
- j. **Error Type 2049 with Aux Data 117:** there is a problem with the fiber optic interface (FOI), that is generating bit errors. Sometimes these bit errors may be constant. This error could be caused by a crimped fiber, a fiber that is not seated correctly in the transceiver, or a defective transceiver.
- k. **Error Type 2305 with Aux Data 118:** the EI circuit pack has detected slips on the incoming fiber data stream. That is, a PN in a Direct Connect configuration, or a PN and a Switch Node in a Center Stage Switch configuration, are not synchronized.
1. Enter `display errors` and follow the repair procedures for non-slip errors against any of the following:

[SYNC \(Port Network Synchronization\)](#)

[TDM-CLK \(TDM Bus Clock\)](#)

[TONE-BD \(Tone-Clock Circuit Pack\)](#)

[DS1C-BD \(DS1 Converter Circuit Pack\)](#)

[EXP-INTF \(Expansion Interface Circuit Pack\)](#)

[SNC-BD \(Switch Node Clock Circuit Pack\)](#)

[SNI-BD \(SNI Circuit Pack\)](#)

Non-slip errors are those not listed below:

| Circuit Pack Name          | Name in Error Log | Log Entry (for Slips) |
|----------------------------|-------------------|-----------------------|
| DS1 Interface              | DS1-BD            | 3073 to 3160          |
| Expansion Interface        | EXP-INTF          | 2305                  |
| SNI                        | SNI-BD            | 1537                  |
| Tone-Clock                 | TDM-CLK           | 1025                  |
| UDS1 Interface             | UDS1-BD           | 3073 to 3160          |
| DS1 converter circuit pack | DS1C-BD           | 3329                  |

2. For slip errors, see [SYNC \(Port Network Synchronization\)](#).
- l. **Error Type 2306** indicates on-board failures related to system timing and synchronization. Perform the [Fiber link fault isolation](#) procedures described in [Chapter 4: General troubleshooting](#) of *Maintenance Procedures (03-300432)*.
- m. **Error Type 2561** indicates an on-board failure of EI circuitry related to handling packet data from the fiber interface and from the packet bus interface.
1. If this error has generated a minor alarm, the EI circuit pack should be replaced.
- n. **Error Type 2817:** on-board failure of EI circuitry related to transmission of data to the fiber interface. If this error has generated a minor alarm, the EI circuit pack or transceiver should be replaced.

- o. **Error Type 3073:** Perform the following steps for Error Type 3073:
1. Execute **display errors** and resolve any errors on the following: PKT-BUS, PKT-INT, BRI-BD, BRI-PT, BRI-SET/ASAI, UDS1-BD.
  2. Enter **test board location r 3** for this circuit pack. If this error continues to appear, replace the EI circuit pack.
- p. **Error Types 3074 and 3075:** failures of the EI circuit pack Packet Path test. The packet path test exercises circuitry on the EI circuit pack, the neighbor EI or SNI circuit pack, and any intervening DS1 converter circuit packs (if the PN is removed).
1. Certain packet bus faults can cause these errors without the EI being defective. Check if PKT-BUS errors are also present. If they are, see [PKT-INT \(Packet Interface\)](#) and [Isolating and repairing packet-bus faults](#) in *Maintenance Procedures (03-300432)* to diagnose the problem.
  2. If Error Type 3075 is present without Error Type 3074, replace the EI circuit pack.
  3. If Error Type 3074 exists with or without 3075, run **test board location** on the EI, and follow the repair procedures for any test that does not pass.
  4. If PKT-BUS errors are absent and replacing the EI does not resolve the problem, there may be a packet bus fault. See [Isolating and repairing packet-bus faults](#) in *Maintenance Procedures (03-300432)*.
- q. **Error Type 3330:** failure of a diagnostic component on the EI circuit pack. The failed component will not impair service, but it may leave the EI circuit pack in a state where the EI circuit pack cannot detect errors.
1. Replace the EI circuit pack at a time when it is most convenient for the customer (this may cause service outages).
- r. **Error Type 3585:** the EI circuit pack experienced a series of very short out-of-frame conditions within several minutes. This may indicate transmission difficulties over the fiber link. If this condition ceases, the warning alarm should be resolved within 15 minutes.
1. Enter **display errors** and resolve any [SNC-BD \(Switch Node Clock Circuit Pack\)](#), [TDM-BUS \(TDM Bus\)](#), [TDM-CLK \(TDM Bus Clock\)](#) or [SYNC \(Port Network Synchronization\)](#) errors.
- s. Perform the [Fiber link fault isolation](#) procedures described in [Chapter 4: General troubleshooting](#) of *Maintenance Procedures (03-300432)*.
1. If the alarm is not resolved within the next 15 minutes, replace the lightwave transceiver on the EI circuit pack reporting the problem and on the connected EI circuit pack, SNI circuit pack, or DS1 converter circuit pack.
  2. If the alarm is not resolved within the next 15 minutes, replace the EI circuit pack reporting the alarm.
  3. If the alarm is not resolved within the next 15 minutes, replace the connected EI circuit pack, SNI circuit pack, or DS1 converter circuit pack.
- t. **Error Type 3841:** the EI has reported a loss of lock with the backplane system clock.

- u. **Error Type 3842:** the test that queries the EI for the state of the lock to the system clock has failed. A loss of lock condition is present.
- v. The counter associated with Error Types 3841 and 3842 is cleared when the query for the state of the clock-to-system-clock passes. Once the alarm is raised, this test is run every five minutes. However, the test is not part of any sequence that can be run on demand. See previous Note [p](#) for the repair procedure.
- w. **Error Type 10001:** the EI circuit pack dropped one control message to the PN. This condition may have been observed as a call that did not complete correctly. No action is required.

---

## Demand test descriptions and error codes

Investigate tests in the order presented. By clearing errors associated with the first test, errors generated from other tests may also be cleared. Click on the link to see the full description of the test, error codes, and recommended actions.

When testing EI circuit packs to investigate problems, tests should always be run on both circuit packs on the associated fiber link, whether the circuit packs are both EI circuit packs, or one is a SNI circuit pack. This will provide a better indication of where a problem is located.

When testing of the EI is not possible, (for example, when the PN is down), see the [Expansion Interface Manual Loopback Procedure](#).

| Order of Investigation                                                           | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |

1. D = Destructive, ND = Nondestructive

## EXP-PN (Expansion Port Network)

### S8700-series Fiber-PNC

| MO Name in Log | Alarm Level | Initial Command to Run <sup>1</sup>      | Full Name of MO        |
|----------------|-------------|------------------------------------------|------------------------|
| EXP-PN         | MAJ         | <code>display errors</code> <sup>1</sup> | Expansion Port Network |

1. Investigate errors against EXP-PN and [EXP-INTF \(Expansion Interface Circuit Pack\)](#).

The EXP-PN MO is responsible for overall maintenance of an Expansion Port Network (EPN) and monitors cross-cabinet administration for compatible companding across the circuit-switched connection. The focus of EPN maintenance is on the EI, the ATM's EI, or the IP Server Interface (IPSI) circuit pack that is acting as the Expansion Archangel link in an EPN. EXP-INTF or ATM-EI or IP-SVR covers maintenance of the EI, ATM EI, or IPSI circuit pack, while EXP-PN covers a much broader area of activities and problems on an EPN. The alarming strategy for EXP-PN is fairly simple and does not make use of any failure analysis routine for spawning maintenance actions. EXP-PN alarming is based on the availability of an EPN for service and the EPN's response to various recovery actions.

When investigating alarms logged against an EPN, problems involving the EI, an ATM EI, or an IPSI circuit pack acting as the Expansion Archangel; problems that may involve loss of communication between the EPN and the server should be investigated. This could ultimately include fiber links (FIBER-LK), DS1 converter circuit packs (DS1C-BD), SNI circuit packs (SNI-BD) and Switch Node Configurations (SN-CONF) for CSS. For ATM, this could include the PN ATM EI (ATM-EI) circuit pack, the ATM switch (ATM-NTWK), and EPN ATM EI (ATM-EI) circuit pack. For TN2312 IPSI circuit packs this could include IP-SVR or IPSV-CTL maintenance objects.

---

## PN Restarts

While not an exhaustive discussion of PN recovery actions, this section describes at a high level the causes and effects of PN restarts so that these Error Log events can be understood.

## PN Warm Restarts

PN Warm Restart (PN Reset Level 1) is generally performed on a PN when the recovery of that PN can be accomplished in less than 30 seconds. When possible, Warm Restart minimizes the work required to reinitialize a PN and reduces the impact of a PN failure by avoiding the longer and highly-destructive PN Cold Restart. The primary cause of PN restarts is failure of the link from the server to the PN due to a hardware fault in the link's path. For most hardware failures this link (and thus the PN) cot be recovered until the failed hardware is replaced. However, several failure modes provide hardware redundancy, allowing the link to be recovered quickly. For instance in duplicated systems, the failure of a Packet Interface circuit pack causes an IPSI interchange that allows the link to be recovered quickly over the newly-active Packet Interface. Or on a Center Stage Switch with multiple fibers interconnecting the switch nodes, a link carried on one fiber can be rerouted over another fiber.

If the Expansion Archangel Link (EAL) is recovered quickly, the PN Warm Restart returns the PN to service with minimal effects on user service. If the EAL cannot be recovered quickly, the PN is taken out of service and a PN Reset Level 2 (PN Cold Restart) is required to return it to service.

## PN Cold Restarts

If the server-to-PN link has failed and has not been recovered within 30 seconds, the PN is taken out of service and can be brought back into service only with a PN Reset Level 2 (PN Cold Restart). Effects of a PN Cold Restart include a reset of every circuit pack in the PN and the disconnection of every call to or from the PN. Calls with both endpoints within the PN are dropped upon recovery.

## PN Restart Escalation

PN restarts follow an escalation strategy controlled by maintenance software. Whenever a request for a PN Reset Level 1 (PN Warm Restart) is made, software checks to see if the restart should be escalated to a PN Reset Level 2 (PN Cold Restart). If any of the following are true, the restart is escalated:

- 1 At least two level 1 restarts have occurred and less than 30 minutes has elapsed since the last occurrence.
- 1 Current PN conditions do not allow a level 1 restart, such as when the PN is out of service.
- 1 Less than 3 minutes has elapsed since the last PN Cold Restart, indicating that the PN is unstable.

If two PN Cold Restarts have been executed in less than an hour and the link is functional, but the PN has not recovered to an in-service state, a MAJOR alarm is raised against EXP-PN, and the PN is put into Emergency Transfer by system software. (Software can invoke PN Emergency Transfer only when the link to the PN is up. If the link is down, the hardware automatically invokes Emergency Transfer 1 minute after it detects a link failure).

---

## Connectivity Alarming

When a PN is out of service, a MAJOR EXP-PN alarm is raised against that PN. A PN can only be alarmed if it is out of service *and* the fiber between the server and the PN is up.

For ATM, a Port Network can only be alarmed if it is out of service and the connections to the server, the ATM switch, and the EPN are up. If the connection from the server to the ATM switch is down (by removing it from administration, for example), every Port Network is lost but not alarmed, since they are not the cause of the problem.

## Error log entries and recommended actions

**Table 110: EXP-PN Error Log Entries**

| Error Type | Aux Data | Associated Test | Alarm Level | On/Off Board | Recommended Action |
|------------|----------|-----------------|-------------|--------------|--------------------|
| 1 (a)      | 0        | None            | None        |              |                    |
| 257 (b)    | 0        | None            | None        |              |                    |
| 513 (c)    | 0        | None            | MAJ         | OFF          |                    |
| 769 (d)    | 0        | None            | MAJ         | OFF          |                    |
| 1025 (e)   | Any      | None            | MAJ         | OFF          |                    |
|            |          |                 |             |              |                    |

Notes:

- a. **Error Type 1:** informational entry only, indicating that a PN Reset Level 1 (PN Warm Restart) has been executed on this PN.
- b. **Error Type 257:** informational entry only, indicating that a PN Reset Level 2 (PN Cold Restart) has been executed on this PN. This does not include restarts done at system initialization time.
- c. **Error Type 513:** indicates that a PN is not in service when it is expected to be. The value specified in the port field of the error log, is the PN number of the affected PN. When this condition occurs, examine every system link error and EXP-INTF or ATM-PNC error to aid in resolving the alarm (examples of system link errors are errors logged against PKT-INTF, EXP-INTF, SNI-BD, FIBER-LK, and PKT-BUS and for ATM, PKT-BUS, ATM-EI, ATM-NTWK). Also check that all fiber connectivity matches that have been administered for the system. This alarm and error is resolved and removed from the logs only when the PN comes back into service.
- d. **Error Type 769:** This alarm is raised when PN maintenance has attempted to execute a Cold Restart recovery action two times, and both restarts failed. This will cause the PN to be placed in Emergency Transfer. Examine every EXP-INTF or ATM-EI error that, when cleared, may aid in resolving this alarm. Also check for any SNI-BD, SNI-PEER, FIBR-LK, SN-CONF, or DS1C-BD errors or for ATM, ATM-EI or ATM-NTWK errors that may indicate a communication problem between the processor and the PN. Make sure that the physical fiber connectivity matches that of system administration.
- e. **Error Type 1025:** If two cabinets are DS1-C connected and their companding modes differ, the system raises a major alarm only if the **Multinational Locations** field is **y** on the **Customer Options** form. See *Administering Avaya Aura™ Communication Manager* for more information about administering multiple locations, particularly the **Locations** form in Screen Reference section.

---

## Demand test descriptions and error codes

There are no demand tests for EXP-PN. Two reset tests, PN Cold Restart Test (#955) and PN Warm Restart Test (#956) can be executed to reset a PN.

The [PN Warm Restart Test \(#956\)](#) restarts a PN that has not been taken out of service. It is the least severe of the PN restart levels and is used in an attempt to preserve the state of the system as much as possible, thereby reducing user impact. The command for this type of restart is `reset port-network P level 1` where P is the port network number.

The [PN Cold Restart Test \(#955\)](#) is used as a recovery mechanism for a PN that has been taken out of service. It is executed as a result of PN recovery escalation when a Warm Restart is not possible, or as a result of a system technician demanded PN restart. Once a PN has gone out of service, a PN Cold Restart is required to bring it back into service. This is the most severe of the PN restarts, and users will experience a service outage. The command for this type of restart is `reset port-network P level 2` where P is the port network number.

## EXT-DEV (External Device Alarm)

G650

| MO Name in Log | Alarm Level | Initial command to run                             | Full name of MO       |
|----------------|-------------|----------------------------------------------------|-----------------------|
| EXT-DEV        | MIN         | <code>test environment location</code>             | External Device Alarm |
|                | MAJ         | <code>test environment location</code>             |                       |
| EXT-DEV        | MIN         | <code>test eda-external-device-alm location</code> | External Device Alarm |
|                | MAJ         | <code>test eda-external-device-alm location</code> |                       |

A TN2312BP IPSI, in a G650 with a carrier address set to A, has two alarm ports that connect to external devices. An example of an external device is an uninterruptible power supply (UPS). Refer to [Figure 66: G650 Cabinet Environmental Hardware Components](#) on page 824 for further information.

Conditions can occur on the external device that close the contacts on the alarm leads. This notifies the switch to originate an EXT-DEV alarm. One set of leads generates a major alarm, the other set generates a minor alarm.

These leads are labeled Major and Minor alarm. The designation of major or minor refers to the lead, not to the severity of the alarm associated with the connection. For example, the major lead can be administered as a major, minor, or warning alarm, and the minor lead can be administered as a major, minor, or warning alarm. Analog line ports can also be administered as external device alarms in the same mer.

If the External Device Alarm feature is enabled on the `change system-parameters customer-options` form, the alarm level and the text string for the alarm condition for each external alarm lead can be administered on the SAT screen using the `add eda-customer-alarm` command. The alarm leads are tested using the `test eda-external-device-alm location` command.

If the External Device Alarm feature is not enabled on the `change system-parameters customer-options` form on the SAT, a contact closure to ground for the Major Alarm lead will generate a Major alarm for EXT-DEV, and a contact closure to ground for the Minor Alarm lead will generate a Minor alarm for EXT-DEV. The alarm leads are tested using the `test environment location` command.

## Error log entries and recommended actions

**Table 111: Test to clear with external device alarm administration enabled**

| Error Type | Aux Data | Associated test                         | Alarm Level | On/Off Board | Recommended Action                                                   |
|------------|----------|-----------------------------------------|-------------|--------------|----------------------------------------------------------------------|
| 1          |          | External Device Alarm Query Test (#120) | MAJ<br>MIN  | OFF          | <code>test eda-external-device-alm<br/>location major   minor</code> |

**Table 112: Test-to-clear without external device alarm administration enabled**

| Error Type | Aux Data | Associated test                         | Alarm Level | On/Off Board | Recommended Action                     |

## EXT-DEV ADMIN? N (External Device Alarm)

S8700 | S8710 | S8720 / S8500

| MO Name in Log | Alarm Level | Initial Command to Run <sup>1</sup> | Full Name of MO       |
|----------------|-------------|-------------------------------------|-----------------------|
| EXT-DEV        | MAJ<br>MIN  | <code>test environment UU</code>    | External Device Alarm |

1. Where **UU** is the cabinet number in the PORT field from the Alarm or Error Log.

### Note:

Use this Maintenance Object when the **External Device Alarm Admin** field on the `change system-parameters customer-options` form is **n**.

**S8700 | S8710 | S8720 | S8500:** The IPSI monitors the EXT-DEV alarm leads.

The system only recognizes pairs connected to the 1M and 1m (ALARM MONITOR) leads. Refer to the *DEFINITY® Communications System Generic 1 and Generic 3i Wiring* (555-204-111) for more details.

| <a href="#">Ring Generator Initialization Test (#117)</a>            | X                   | X                  | ND                |
| <a href="#">Ring Generator Query Test (#118)</a>                     | X                   | X                  | ND                |

1. D = Destructive; ND = Nondestructive

## EXT-DEV ADMIN? Y (External Device Alarm)

S8700 | S8710 | S8720 / S8500

| MO Name in Log | Alarm Level       | Initial Command to Run <sup>1</sup>          | Full Name of MO       |
|----------------|-------------------|----------------------------------------------|-----------------------|
| EXT-DEV        | MAJ<br>MIN<br>WRN | <code>test eda-external-device-alm UU</code> | External Device Alarm |

1. **UU** is a cabinet number determined in the `Port` field of the Alarm or Error Log.

**Note:**

Use this MO when the `External Device Alarm Admin` field on the **change system-parameters customer-options** screen is **y**. You must have INADS or INIT login permissions to administer EXT-DEV Alarm.

---

S8700 | S8710 | S8720 / S8500

Each PN's Maintenance circuit pack has two alarm ports that connect to such external devices as uninterruptible power supplies (UPSs) or adjuncts (e.g., AUDIX).

Certain conditions on the external device close the contacts on the alarm leads to notify the switch that in turn originates an EXT-DEV alarm. One set of leads generates a major alarm; the other set generates a minor alarm.

The special locations *UUmajor* and *UUmminor* designate the major or minor Maintenance board's alarm connection for cabinet UU. The major/minor designation specifies the port, not the alarm level associated with the connection; *for example*, the "major" port can be administered as a major, minor, or warning alarm, and the "minor" port can be administered as a major, minor, or warning alarm. In addition Analog line ports can also be administered as external device alarms.

**Note:**

An un-administered Maintenance board's external device alarm port, that is sensing a contact closure will have an entry in the Error Log and in the Alarm Log. The alarm receiver will not receive warning alarms.

---

## Error log entries and recommended actions

| Error Type | Aux Data | Associated Test                   | Alarm Level | On/Off Board | Recommended Action                                                  |
|------------|----------|-----------------------------------|-------------|--------------|---------------------------------------------------------------------|
| 0          | 0        | Any                               | Any         | Any          | <code>test eda-external-device-alm physical-location r 2   6</code> |
| 1 or 5     | Any      | External Device Alarm test (#120) | Any         | OFF          | <code>test eda-external-device-alm physical-location r 2   6</code> |

**Note:**

The loss of -48 volt power prevents detection of an external device alarm. AC-POWER, CARR-POW, and DC-POWER alarms could indicate the loss of the external device alarm -48 volt power source. ALARM-PT alarms may also indicate a loss of power. When analog line ports are administered as analog line external device alarms loss of -48 volts prevents detection of an external device alarm.

## Demand tests descriptions and error codes

1. D = Destructive; ND = Nondestructive

## FIBER-LK (Fiber Link)

| MO Name in Log | Alarm Level       | Initial Command to Run <sup>1</sup>  | Full Name of MO |
|----------------|-------------------|--------------------------------------|-----------------|
| FIBER-LK       | MAJ<br>MIN<br>WRN | <code>test fiber-link F pnc s</code> | Fiber Link      |

1. *F* is the fiber link number; *pnc* is either "a-pnc" or "b-pnc" (always "a-pnc" for a standard-, high-, or critical-reliability system).

A fiber link consists of the endpoint boards that are connected via the optical fiber, the lightwave transceivers or metallic connections on the endpoint boards, and, if administered, the DS1 Converter (DS1 converter) complex that exists between the two fiber endpoints. The fiber endpoints are EI circuit packs and/or SNI (SNI) circuit packs.

Three types of fiber links exist in the system:

|                |                                                                                                                                                                |
|----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| EI-to-EI fiber | This type of fiber is an EI-to-EI connection and is only used in direct connect PNC.                                                                           |
| EI-SNI fiber   | This type of fiber is an EI-to-SNI connection and is only used in Center Stage Switch (CSS) PNC.                                                               |
| SNI-SNI fiber  | This type of fiber is an SNI-to-SNI connection and is only used in CSS PNC when two switch node carriers are connected in a 2- or 3-switch node configuration. |

Fiber link errors and alarms are generated only on fibers that have at least one SNI endpoint. Fiber errors for fibers that have EIs as both endpoints are detected by the EI circuit pack, thus generating off-board EXP-INTF errors and alarms. Fiber errors and alarms on EI-SNI fiber links generate FIBER-LK and/or off-board EXP-INTF errors and alarms.

Fiber links are administered via `add fiber-link F` or `add fiber-link next`, where *F* is the fiber link's number. The 2 endpoints of the fiber are administered (EI and EI, EI and SNI, or SNI and SNI). In a duplicated PNC configuration, both the A- and B-PNC's fiber links are assigned with the same fiber link's number. The fiber links are designated by *F P*, where *F* is the fiber link's number and *P* is the PNC, A-PNC or B-PNC. In addition, a DS1 converter complex may be assigned to the fiber link. In a duplicated PNC configuration, both the A- and B-PNC's DS1 converter complexes are administered with the same fiber link's number. DS1 facilities and parameters can be modified via `change fiber-link F P`.

Use `display fiber-link F` to see an individual fiber link. Use `list fiber-link` to see every fiber link.

The following terms are used in the error descriptions:

|              |                                                                                                                                     |
|--------------|-------------------------------------------------------------------------------------------------------------------------------------|
| Control Path | The path between the two fiber endpoints that is necessary for the two endpoint circuit packs to communicate.                       |
| Circuit Path | The path between the two fiber endpoints that is necessary for circuit switched phone calls to work.                                |
| Neighbor     | The circuit pack on the other end of the fiber.                                                                                     |
| Out of Frame | A circuit pack reports fiber out of frame if it cot detect valid data coming from the fiber.                                        |
| Packet Path  | The path between the two fiber endpoints that is necessary for packet-switched messages to be sent between the two fiber endpoints. |

---

## LEDs for Circuit Packs on a Fiber Link

The amber LEDs on the three types of boards, SNI (TN573), EI (TN570), and DS1 Converter (TN574 or TN1654), that may be a part of the fiber link can help in diagnosing problems with the fiber link. The amber LED states are as follows. The flashing LED patterns take precedence over the active or standby LED patterns.

If both endpoints of a fiber link (EI and/or SNI) are flashing with a fiber out of frame pattern, a fast amber LED pattern (0.1 second on and 0.1 second off), check the lightwave transceivers (if present). Both lightwave transceivers on the fiber link must be of the same type. The 9823a shortwave transceiver and the 9823b longwave transceiver must never be combined on the same fiber link because a fiber out-of-frame condition will exist. The 9823a lightwave transceiver should be used for distances up to 4900 feet and the 9823b lightwave transceiver should be used for distances up to 25,000 feet.

**Table 115: SNI Amber LED Flashing Codes**

| Condition                          | LED on     | LED off    |
|------------------------------------|------------|------------|
| Fiber out of Frame                 | 0.1 second | 0.1 second |
| In Frame, No Neighbor <sup>1</sup> | 0.5 second | 0.5 second |
| SNI active                         | Solid on   | Never off  |
| SNI standby                        | Never on   | Solid off  |

1. The fiber is in frame, but no communication exists to the neighbor

**Table 116: Expansion Interface Circuit Pack Amber LED Flashing Codes**

| Condition                       | LED on     | LED off    |
|---------------------------------|------------|------------|
| Fiber Out-of-Frame              | 0.1 second | 0.1 second |
| In frame-No Neighbor (a)        | 0.5 second | 0.5 second |
| Expansion Interface Active (b)  | 2 second   | 0.2 second |
| Expansion Interface Active (c)  | Solid on   | Never off  |
| Expansion Interface Standby (d) | Never on   | Solid off  |

## Notes:

- a. The fiber is in frame, but no communication exists to the neighbor.
- b. This is the normal state for an active PN EI circuit pack that is also the bus master (expansion Archangel) in the PN.
- c. This is the normal state for an active EI circuit pack that is not the bus master (expansion Archangel) for a PN. This applies only in the direct connect configuration where the EI circuit pack in a PN connects via a fiber link to an EI circuit pack in the other PN. This state also applies for an active EI circuit pack located in the PN.
- d. This is the normal state for a standby expansion Interface circuit pack in the PN.

For more details about how the EI circuit pack error codes relate to the LED states, see [EXP-INTF \(Expansion Interface Circuit Pack\)](#).

**Table 117: DS1 Converter Amber LED Flashing Codes**

| Condition                                  | LED on     | LED off    |
|--------------------------------------------|------------|------------|
| Fiber out of Frame (a)                     | 0.1 second | 0.1 second |
| In frame, fiber channel is down (b)        | 0.5 second | 0.5 second |
| In frame, DS1 channel down (c)             | 1 second   | 1 second   |
| DS1 converter, no response from server (d) | 2 second   | 0.2 second |
| DS1 converter active                       | Solid on   | Never off  |
| DS1 converter standby                      | Never on   | Solid off  |

## Notes:

- a. A Fiber is out of frame or a fiber loss-of-signal condition exists.
- b. DS1 converter/fiber endpoint communication is down.
- c. The DS1 channel is down between the two DS1 converters in the DS1 converter complex.

- d. The server is not acknowledging messages from the DS1 converter circuit pack or the DS1 converter circuit pack does not have a processor route. This pattern indicates a probable software problem.

In addition to the traditional red, green, and amber LEDs, the DS1 converter circuit pack has four green LEDs that indicate whether a receive signal is present for each DS1 facility.

## Error log entries and recommended actions

**Table 118: FIBER-LK Error Log Entries**

| Error Type     | Aux Data | Associated Test                | Alarm Level       | On/Off Board | Recommended Action               |
|----------------|----------|--------------------------------|-------------------|--------------|----------------------------------|
| 0 <sup>1</sup> | 0        | Any                            | Any               | Any          | <code>test fiber-link F P</code> |
| 1 (b)          | any      | Failure audit (#777) (a)       | MAJ<br>MIN<br>WRN | OFF          | <code>test fiber-link F P</code> |
| 18 (c)         | 0        | <code>busyout fiber F P</code> | WRN               | OFF          | <code>release fiber F P</code>   |
| 257 (d)        | any      | Failure audit (#777) (a)       | MAJ<br>MIN<br>WRN | OFF          | <code>test fiber-link F P</code> |
| 513 (e)        | any      | Failure audit (#777) (a)       | MAJ<br>MIN<br>WRN | OFF          | <code>test fiber-link F P</code> |
| 769 (f)        | any      | Failure audit (#777) (a)       | MAJ<br>MIN<br>WRN | OFF          | <code>test fiber-link F P</code> |
| 1025 (g)       | any      | Failure audit (#777) (a)       | MAJ<br>MIN<br>WRN | OFF          | <code>test fiber-link F P</code> |
| 1281 (h)       | any      | Failure audit (#777) (a)       | MAJ<br>MIN<br>WRN | OFF          | <code>test fiber-link F P</code> |

1. Run the short test sequence first. If every test passes, run the long test sequence. Refer to each appropriate test's description, and follow its recommended procedures.

Notes:

- a. The [Failure Audit \(#777\)](#) should be run to confirm whether the error still exists.
- b. **Error Type 1:** problem with the control path to the neighbor. See [Repair procedures](#).

- c. **Error Type 18:** the fiber link has been busied out via `busyout fiber-link F P`. To resolve this error, use `release fiber-link F P` to release the fiber link.
- d. **Error Type 257:** problem with the circuit path to the neighbor. See [Repair procedures](#).
- e. **Error Type 513:** problem with the packet path to the neighbor. See [Repair procedures](#).
- f. **Error Type 769:** problem with the control path from the neighbor. See [Repair procedures](#).
- g. **Error Type 1025:** problem with the circuit path from the neighbor. See [Repair procedures](#).
- h. **Error Type 1281:** problem with the packet path from the neighbor. See [Repair procedures](#).

## Repair procedures

For Note [b](#) and Notes [d](#) through [h](#), perform the following steps:

1. Perform the [Fiber link fault isolation](#) in [Chapter 4: General troubleshooting](#) in *Maintenance Procedures (03-300432)*.
2. Enter `display errors` and if any of the listed slip errors exist, follow the associated repair procedures in [SYNC \(Port Network Synchronization\)](#) for slip errors.

**Table 119: Error Log Entries for Slip Errors**

| Circuit Pack Name   | Error Log Name | Number of Slips |
|---------------------|----------------|-----------------|
| DS1 Interface       | DS1-BD         | 3073 to 3160    |
| Expansion Interface | EXP-INTF       | 2305            |
| SNI                 | SNI-BD         | 1537            |
| Tone-Clock          | TDM-CLK        | 1025            |
| UDS1 Interface      | UDS1-BD        | 3073 to 3160    |

1. D = Destructive; ND = Nondestructive

## FW-DWNLD (Firmware Download)

| MO Name in Log | Alarm Level        | Initial command to run                           | Full Name of MO   |
|----------------|--------------------|--------------------------------------------------|-------------------|
| FW-DWNLD       | MINOR <sup>1</sup> | <code>test firmware<br/>download location</code> | Firmware Download |

1. MINOR alarms can be downgraded to WARNING by using the `set options` command.

Firmware Download provides the capability to download new firmware to one or more programmable circuit packs of the same type residing within the same system. Programmable circuit packs have a “P” in their suffix. For example, the TN799DP is programmable, but the TN799C is not. This programmable capability reduces the need to physically remove circuit packs and return them to Avaya for firmware updates.

Check availability for circuit packs on the Avaya Support Web Site at <http://support.avaya.com>

See [Firmware Download Instructions](#) for the firmware download procedures.

---

## Reason codes and `fwdlreason` command

The SAT command `status firmware download schedule` displays reason codes for firmware download failures and aborts, where *schedule* is **1**, **2**, **3**, **4**, or **last**, which displays the most recent status of a specific schedule.

The bash command `fwdlreason -c code` displays an explanation of the reason code. For example, `fwdlreason -c 6266` will display an explanation regarding digital signature validation and that an error occurred during the firmware image unpack.

---

## Error log entries and recommended actions

[Table 123: FW-DWNLD Error Log Entries](#) shows the error log entries and tests which apply to self- and C-LAN distributed downloads, *not to IPSI downloads*.

**Table 123: FW-DWNLD Error Log Entries 1 of 2**

| Error Type | Aux Data | Cause of Error   | Alarm Level | On/Off Board | Recommended Action                           |
|------------|----------|------------------|-------------|--------------|----------------------------------------------|
| 257 (a)    | See note | Download failure | MIN         | OFF          | <code>test firmware download location</code> |

**1 of 2**

Table 123: FW-DWNLD Error Log Entries 2 of 2

| Error Type | Aux Data | Cause of Error            | Alarm Level | On/Off Board | Recommended Action                           |
|------------|----------|---------------------------|-------------|--------------|----------------------------------------------|
| 258 (b)    | See note | Download failure          | MIN         | OFF          | <code>test firmware download location</code> |
| 259 (c)    | See note | Download failure          | MIN         | OFF          | <code>test firmware download location</code> |
| 513 (d)    | See note | Download failure          | MIN         | OFF          | <code>test firmware download location</code> |
| 769 (e)    | See note | Firmware download request | MIN         | OFF          | <code>test firmware download location</code> |
|            |          |                           |             |              | <b>2 of 2</b>                                |

Notes:

- a. **Error Type 257** — System resources error. This error is caused by either the source board, target board, or the firmware image itself. To resolve the error, use the `test firmware download` command. The Aux Data specifies the resource that caused the error. See [Table 124: Aux Data for Error Type 257](#) for more details.

Table 124: Aux Data for Error Type 257 1 of 2

| Aux Data      | Description of Failure                                                                                                              |
|---------------|-------------------------------------------------------------------------------------------------------------------------------------|
| 1             | Source board query failed.<br>1. Check for system-wide problems.<br>2. Clear every error.<br>3. Retry the download.                 |
| 2             | Target board query failed.<br>1. Check for system-wide problems.<br>2. Clear every error.<br>3. Retry the download.                 |
| 3             | Could not allocate resources for download.<br>1. Check for system-wide problems.<br>2. Clear every error.<br>3. Retry the download. |
| <b>1 of 2</b> |                                                                                                                                     |

**Table 124: Aux Data for Error Type 257 2 of 2**

| Aux Data      | Description of Failure                                                                                                                     |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------|
| 4             | Firmware Download Information table query failed.<br>1. Check for system-wide problems.<br>2. Clear every error.<br>3. Retry the download. |
| 5             | Header information message failed.<br>1. Check for system-wide problems.<br>2. Clear every error.<br>3. Retry the download.                |
| 6             | Download Map timer expired.<br>1. Check for system-wide problems.<br>2. Clear every error.<br>3. Retry the download.                       |
| 7             | Download schedule information query failed.<br>1. Check for system-wide problems.<br>2. Clear every error.<br>3. Retry the download.       |
| <b>2 of 2</b> |                                                                                                                                            |

- b. **Error Type 258** — An error indicating that a source board-related error occurred. The download schedule can also abort/fail. To resolve the error, use the command `test firmware download`. The Aux Data specifies the error. See [Table 125: Aux Data for Error Type 258](#) for more details.

**Table 125: Aux Data for Error Type 258 1 of 6**

| Aux Data      | Description of Failure                                                                                                                                                                                                                                                                                                                   |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1             | The Download image file specified on the <code>change firmware download</code> screen is not present on the source board.<br>1. Use the <code>list directory board location</code> command to verify the image exists in the file system's directory.<br>2. Retry the download command.<br>3. If the error recurs, escalate the problem. |
| 2             | The image on the source board has an invalid header.<br>1. Retry the download command.<br>2. If the error recurs, escalate the problem.                                                                                                                                                                                                  |
| <b>1 of 6</b> |                                                                                                                                                                                                                                                                                                                                          |

Table 125: Aux Data for Error Type 258 2 of 6

| Aux Data      | Description of Failure                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

- c. **Error Type 259** — problem on the target board. To resolve the error, use the command `test firmware download`. The Aux Data specifies the error. See [Table 126: Aux Data for Error Type 259](#) for more details.

**Table 126: Aux Data for Error Type 259 1 of 3**

| Aux Data      | Description of Failure                                                                                                       |
|---------------|------------------------------------------------------------------------------------------------------------------------------|
| 1             | Target board is not present or not responding.<br>1. Check board's location and translations.<br>2. Retry the download.      |
| 2             | Incorrect target board for download schedule.<br>1. Verify board's location and download schedule.<br>2. Retry the download. |
| 3             | Target failed to go into Download Mode.<br>1. Retry the download.                                                            |
| 4             | Target received bad file header.<br>1. Get a new image.<br>2. Retry download.                                                |
| <b>1 of 3</b> |                                                                                                                              |

**Table 126: Aux Data for Error Type 259 2 of 3**

| <b>Aux Data</b> | <b>Description of Failure</b>                                                                                                                                                                                                                                                                                                                                                                                                           |
|-----------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 5               | Bad checksum on source board's image.<br>1. Get a new image.<br>2. Retry download.                                                                                                                                                                                                                                                                                                                                                      |
| 6               | TFTP protocol error – One reason for this type of failure may be that the target board is located in a DS1-C remote PN using ami-zcs line coding to communicate with the server. To have a successful firmware download you must have a clear channel between the source and target board, or the source and target must reside in the remote PN. Some examples of the correct type of line coding for this feature are: b8zs and hdb3. |
| 7               | File transfer timer expired.<br>1. Check the board's location and translations.<br>2. Retry download.<br>3. If the error recurs, escalate the problem.                                                                                                                                                                                                                                                                                  |
| 8               | Target failed to reset after transfer.<br>1. Check the board's location and translations.<br>2. Retry download.<br>3. If the error recurs, escalate the problem.                                                                                                                                                                                                                                                                        |
| 9               | Could not allocate resources for the target board.<br>1. Retry the download command.<br>2. If the error recurs, escalate the problem.                                                                                                                                                                                                                                                                                                   |

Retry download.                                                                                                                                                                                                                                                                                                                                     |
| 13              | The target board rejected the download image.<br>1. Check the board's translations.<br>2. Verify the image file.<br>3. Retry the download command.<br>4. If the error recurs, escalate the problem.                                                                                                                                                                                                                                     |
| 20              | Could not open the requested file – firmware error on target board.                                                                                                                                                                                                                                                                                                                                                                     |
| 21              | Problem reading the requested file – firmware error on target board.                                                                                                                                                                                                                                                                                                                                                                    |
| 22              | The download file has a bad CRC – firmware error on target board.                                                                                                                                                                                                                                                                                                                                                                       |
| 24              | A download is already in progress – firmware error on target board.                                                                                                                                                                                                                                                                                                                                                                     |

**2 of 3**

**Table 126: Aux Data for Error Type 259 3 of 3**

| Aux Data      | Description of Failure                                                                                                        |
|---------------|-------------------------------------------------------------------------------------------------------------------------------|
| 30            | Download sequence error – firmware error on target board.                                                                     |
| 32            | The file name is too long – firmware error on target board.                                                                   |
| 40            | FLASH programming failed – Internal firmware error on target board.<br>1. Retry the download, and escalate if it still fails. |
| <b>3 of 3</b> |                                                                                                                               |

d. **Error Type 513** — the schedule has failed. A schedule failure can result from:

- 1 Any of the previously mentioned log-only errors (257 – 259)
- 1 An expiration of the schedule timer
- 1 An execution of `disable firmware download` command

To resolve the error and clear the alarm, use the `test firmware download` command. The Aux Data specifies the reason why the schedule failed. See [Table 127: Error Type 513 Aux Data](#) for more details.

**Table 127: Error Type 513 Aux Data**

| Aux Data | Description of Failure                                                                                                                      |
|----------|---------------------------------------------------------------------------------------------------------------------------------------------|
| 1        | Software resources not available; see Error Type 257 (a).                                                                                   |
| 2        | Source board-related failure; see Error Type 258 (b).                                                                                       |
| 3        | A target board failed. See Error Type 259 (c).<br>1. Check the image, translations and retry the download                                   |
| 4        | Two consecutive target boards failed, download schedule aborted.<br>1. Verify the download image and translations.<br>2. Retry the download |
| 5        | Schedule timer expired<br>1. Schedule unfinished target boards.<br>2. Retry the download.                                                   |
| 6        | <code>disable firmware download</code> command was executed.                                                                                |
|          |                                                                                                                                             |

e. **Error Type 769** — a downloadable board image is bad and a good image needs to be downloaded. This error may be a result of a failed download attempt or a board that is unstable. The Aux Data indicates the location of the circuit pack requesting the firmware

download and is in the form UUAAA, where UU is the port network number (cabinet) and AAA is the Angel number.

The Angel number can be converted into the carrier and slot number by using the EPN Angel Address/Slot Mapping Table. For example, with an Aux Data value of 1080, look for the Angel number 80 in [Table 7: EPN Angel Address/Slot Mapping](#). It can be found in the column of carrier B and in the row of slot 15, so the target board is located in 1B15.

---

## Demand test descriptions and error codes

The FW-DWNLD maintenance object has only one demand test.

| Order of Investigation                         | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|------------------------------------------------|---------------------|--------------------|-------------------|
| <a href="#">Firmware Download Test (#1413)</a> | X                   | X                  | D                 |

1. D = Destructive; ND = Nondestructive

## FW-STD L (Firmware Station Download)

| MO Name  | Alarm Level | Initial Command To Run                      | Full Name of MO           |
|----------|-------------|---------------------------------------------|---------------------------|
| FW-STD L | WRN         | <code>test firmware station-download</code> | Firmware Station Download |

The Firmware Station Download feature provides the ability to download new firmware to one or more DCP stations of the same type residing in the same system.

The download image is copied from a tftp file server into Communication Manager memory through the `change tftp` command. The transfer of the download image from Communication Manager memory to the target station is done under switch software control. The image is downloaded to the target stations flash through the `change firmware station-download` command. The target stations must be connected and in service to receive the firmware image.

---

### Firmware station download commands

The following is a list of commands associated with the Firmware Station Download feature.

- 1 `change tftp-server` - copies the firmware image from the FTP file server into Communication Manager memory.
- 1 `change firmware station-download` - set up a station download schedule.
- 1 `disable firmware station-download` - cancel an existing station download schedule while allowing any active terminal downloads to complete.
- 1 `display firmware station-download` - displays information for the current download schedule.
- 1 `status firmware station-download` - displays the status of the current scheduled download or the one that has just finished if there were errors in any of the downloads. Use the following tables for details on the schedule status and interpretation of error codes:
  - [Table 131: Schedule States of status firmware station-download](#) on page 486
  - [Table 132: Reason Codes for status firmware station-download](#) on page 487
- 1 `status firmware station-download last` - displays the status of the previously completed scheduled download.
- 1 `test firmware station-download` - resolves any alarms/errors associated with firmware station download (FW-STD L).

---

## Downloading firmware to DCP stations

Updated firmware can be downloaded to up to 1000 Avaya DCP stations. This eliminates the need to use a FAC (feature access code) to perform the firmware update for each station. To download firmware to these stations, Communication Manager requires:

- 1 A valid firmware image loaded into Communication Manager memory through the `change tftp` command.
- 1 Avaya Communication Manager 2.0 or greater software.
- 1 Craft login.

The high-level process for downloading the firmware is to:

1. [Download the firmware image](#)
2. [Read the image into memory](#)
3. [Schedule the download](#)

The target stations are automatically taken out of service before the firmware is downloaded to them and automatically returned to service after the download is completed. Once a download has started, the station cannot be used until the download completes. If a station is in use at the time that it is scheduled to be downloaded, the download to that station will be aborted and the call will not be affected. The `status firmware station-download` command and the error log will provide information on aborted downloads.

### Download the firmware image

Customers can access and download the firmware image on site using the Avaya Customer Support Web site.

1. Go to the Avaya Customer Support Web site (<http://support.avaya.com/>).
2. From the Support menu, select **Software & Firmware Downloads**.
3. Select the firmware image(s) needed from the list provided.
4. Download the file(s) to a temporary directory on a PC that has FTP and network access to the Avaya server.

## Read the image into memory

Before the firmware can be downloaded to the target stations, the image file must first be read into Communication Manager memory:

1. On the System Access Terminal (SAT) using the craft login and password, enter **change tftp-server**

The **TFTP Server Configuration** form displays the following:

```
change tftp-server Page 1 of 1

 TFTP Server Configuration

Local Node Name: clan1
TFTP Server Node Name: tftpserv1
TFTP Server Port: 69
File to Retrieve: 2420v01.bin

File Status:
File Size:
Filename in Memory:

Station Type:
```

2. Enter the node name of the C-LAN that connects over the LAN to the FTP file server in the **Local Node Name** field.
3. Enter the host name of the FTP file server in the **TFTP Server Node Name** field.
4. Enter the port number in the **TFTP Server Port** field.
5. Enter the name of the **File to Retrieve** from the FTP file server and submit the command.
6. Enter **display tftp-server**

```
display tftp-server

 TFTP Server Configuration

Local Node Name: clan1
TFTP Server Node Name: gingerale
TFTP Server Port: 69
File to Retrieve: 2420v015.bin

File Status: File download successful
File Size: 236
Filename in Memory: 2420v015.bin

Station Type: 2420
```

7. Verify the file download was successful by checking the **File Status** field.

## Schedule the download

The new firmware image can be downloaded immediately or scheduled for a later time. Due to the potentially large volume of switch activity as a result of the firmware download, Avaya recommends that the download be scheduled for a time when the system will be at its lowest possible occupancy level. This will also limit the number of stations that are aborted because they were in use at the scheduled download time.

To schedule a station firmware download:

1. On the System Access Terminal (SAT) using craft login and password, enter **change firmware station-download**

The **Firmware Station-Download** form displays the following:

```
change firmware station-download Page 1 of 1
 FIRMWARE STATION-DOWNLOAD

Source File: 2420v01.bin

Schedule Download? y
Start Date/Time: 10/15/2006 20:00 Stop Date/Time: 10/15/2006 23:00
Continue Daily Until Download Complete? y

Download Station Type: 2420

Beginning Station: 85001 Ending Station: 86000
```

2. Select parameters for the download:
  - 1 Enter the firmware filename in the **Source File** field.
  - 1 If you want to schedule the download for a later date/time, enter **y** in the **Schedule Download** Field.
    - Enter a start time in the **Start Date/Time** field.
    - Enter a stop time in the **Stop Date/Time** field.
    - If you want to stop the firmware download at the scheduled stop date/time and resume the next day at the scheduled start time, enter **y** in the **Continue Daily Until Download Complete** field.
  - 1 Enter extension numbers in the **Beginning Station** and **Ending Station** fields (maximum 1,000 stations). Only administered stations within this range with a set type matching the **Station Type** (in this case, Avaya 2420 DCP sets) displayed on this page are available for download.
3. Submit the command.

## Troubleshooting firmware download problems

You cannot start a station download while there are active FW-STD L alarms. To clear all active FW-STD L alarms, use `test firmware station-download`. In the event of an FW-STD L alarm, you can find more details by using the `status firmware station-download` command.

```

status firmware station-download Page 1 of 1
 STATUS FIRMWARE STATION DOWNLOAD

Image File: 2420v01.bin
Schedule Download? y Continue daily until completed?: y
Start Date/Time: 10/15/2006 20:00 Stop Date/Time: 10/15/2006 23:00
 Status for this download: Active

Terminal type for download: 2420
Extension Range: 85001 to: 86000 Number of stations in range: 35

Stations completed: 0 Stations unsuccessful: 1

Extension Status Error Extension Status Error Extension Status Error

85001 ABRT 513
85002 ACTV
85017 ACTV
85034 ACTV

```

This command displays the **Extension** of the terminal, the **Status**, and a **Error** code if applicable. All aborted (ABRT), failed (FAIL), and actively downloading (ACTV) terminals are listed on this screen; pending or completed downloads are not listed. See [Table 132: Reason Codes for status firmware station-download](#) on page 487 for a list of these errors and their descriptions.

## Error log entries and recommended actions

Table 128: FW-STD L Error Log entries 1 of 2

| Error Type | Aux Data | Associated Test | Alarm Level | On/Off Board | Recommended Action                          |
|------------|----------|-----------------|-------------|--------------|---------------------------------------------|
| 257 (a)    | 1        |                 | WRN         | OFF          | <code>test firmware station-download</code> |
| 257        | 2        |                 | WRN         | OFF          | <code>test firmware station-download</code> |
| 257        | 3        |                 | WRN         | OFF          | <code>test firmware station-download</code> |
|            |          |                 |             |              | <i>1 of 2</i>                               |

**Table 128: FW-STDL Error Log entries 2 of 2**

| Error Type | Aux Data | Associated Test | Alarm Level | On/Off Board | Recommended Action             |
|------------|----------|-----------------|-------------|--------------|--------------------------------|
| 257        | 4        |                 | WRN         | OFF          | test firmware station-download |
| 257        | 12       |                 | WRN         | OFF          | test firmware station-download |
| 257        | 13       |                 | WRN         | OFF          | test firmware station-download |
| 257        | 14       |                 | WRN         | OFF          | test firmware station-download |
| 257        | 15       |                 | WRN         | OFF          | test firmware station-download |
| 258 (b)    | 5        |                 | WRN         | OFF          | test firmware station-download |

Notes:

- a. **Error Type 257:** The problem originated with the target terminal. Resolve the alarm with the `test firmware station-download` command. The Aux Data values associated with Error Type 257 are described in [Table 129: Error Type 257 Aux Data descriptions](#).

**Table 129: Error Type 257 Aux Data descriptions 1 of 2**

| Aux Data      | Description                                                                  |
|---------------|------------------------------------------------------------------------------|
| 1             | Terminal failed to erase its program flash.                                  |
| 2             | Target image file checksum is bad.                                           |
| 3             | Target image is incompatible with the terminal (Avaya 2420 DCP sets only).   |
| 4             | Target terminal rejected image as invalid.                                   |
| 12            | Target terminal fails to go into the download mode, timeout occurred.        |
| 13            | Station firmware download engine timed out waiting for download to complete. |
|               |                                                                              |
| <b>1 of 2</b> |                                                                              |

Table 129: Error Type 257 Aux Data descriptions 2 of 2

| Aux Data      | Description                                                                     |
|---------------|---------------------------------------------------------------------------------|
| 14            | Station firmware download to a terminal had too many retries, timeout occurred. |
| <b>2 of 2</b> |                                                                                 |

b. **Error Type 258 with Aux Data 5:** one or more terminals in the download list were skipped and not downloaded because the terminal was not in the appropriate state (in-service and idle). Resolve the alarm with the `test firmware station-download` command. This error can be caused by any of these problems:

- 1 One or more target terminals were busied out by craft
- 1 One or more target terminals were in use when the download attempt was made.
- 1 One or more target terminals were out of service for an unknown reason.

Use the `status firmware station-download` command in conjunction with [Table 132: Reason Codes for status firmware station-download](#) to determine the specific cause of the failure to download.

c. **Error Type 513:** indicates a firmware download error that is not necessarily caused by the target terminal. This error will cause the firmware download process to be stopped. Resolve the alarm with the `test firmware station-download` command. The Aux Data values associated with Error Type 513 are described in [Table 130: Error Type 513 Aux Data descriptions](#).

Table 130: Error Type 513 Aux Data descriptions 1 of 2

| Aux Data      | Description                                                                                                                                                                                                                                                                                                                                                           |
|---------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 4             | Two consecutive terminals failed to download with a failure indicating that the terminals did not accept the firmware image. It is likely that any remaining terminals will also fail, so the scheduled download is stopped and any terminals in the download list that are not yet downloaded are aborted.                                                           |
| 8             | The download image file is not present. The <code>change firmware station-download</code> form requires that the image file be present before the form can be brought up. This error indicates a problem with the image file. As a result of this failure, the schedule cot continue, and any terminals in the download list that are not yet downloaded are aborted. |
| 11            | There was a system error in the download process, possibly due to interprocess calls. Escalate the problem.                                                                                                                                                                                                                                                           |
| <b>1 of 2</b> |                                                                                                                                                                                                                                                                                                                                                                       |

**Table 130: Error Type 513 Aux Data descriptions 2 of 2**

| Aux Data      | Description                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
|---------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 13            | Two consecutive terminals failed to download due to internal timeouts. It is likely that all terminals will fail as well so the schedule is stopped and any remaining terminals in the download list are aborted.                                                                                                                                                                                                                                                                                                                                                                                        |
| 14            | Could not build a list of terminals from the range specified on the <b>change firmware station-download</b> form. Check the administered stations for exact extension numbers.                                                                                                                                                                                                                                                                                                                                                                                                                           |
| 15            | The scheduled stop time was reached without completion of all scheduled terminals. The <b>status firmware station-download</b> command indicates all terminals not downloaded with a status of ABRT and a Reason Code of 3 (see <a href="#">Table 132: Reason Codes for status firmware station-download</a> ). If the <b>Continue daily until completed</b> field is <b>y</b> , this error will not occur because the continuation option causes the schedule to resume the next day at the scheduled start time (see <a href="#">Table 131: Schedule States of status firmware station-download</a> ). |
| <b>2 of 2</b> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

**Table 131: Schedule States of status firmware station-download 1 of 2**

| State          | Schedule Done? | Description                                                                                                                                                                                                                                                                   |
|----------------|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Idle           | No             | There are no downloads Pending or Active, or there are no unresolved errors/alarms for the last download                                                                                                                                                                      |
| Pending        | No             | Download has been scheduled but not yet started. Check the start time to see when it is scheduled to start.                                                                                                                                                                   |
| Active         | No             | Download is currently active. Actively downloading terminals should be listed with a status of ACTV. If the schedule has just started and no downloads are listed, the system may be waiting for a FAC requested or terminal requested download to complete before it begins. |
| Resume-pending | No             | Download was stopped at the Stop Date/Time but not all of the terminals have been attempted. Downloading will resume at the scheduled Start Date/Time listed on the screen.                                                                                                   |
| Aborted        | Yes            | Download was aborted for the entire range of terminals. This could happen if the firmware image was bad, damaged or disappeared.                                                                                                                                              |
| <b>1 of 2</b>  |                |                                                                                                                                                                                                                                                                               |

**Table 131: Schedule States of status firmware station-download 2 of 2**

| State         | Schedule Done? | Description                                                                                                                                                                                                                                                                                                                          |
|---------------|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Failed        | Yes            | At least two terminals rejected the firmware as invalid. As a result, the download was aborted to avoid problems with any further terminals. Check the Reason Codes of the failed terminals in the list to find the reason why the download failed ( <a href="#">Table 132: Reason Codes for status firmware station-download</a> ). |
| Completed     | Yes            | The scheduled download has completed either due to all terminals in the range of extensions having completed or due to the stop timer.                                                                                                                                                                                               |
| Disabled      | Yes            | An Active schedule was disabled with the <code>disable firmware station-download</code> command. After an active schedule is disabled, the Schedule state remains Active until all currently active terminal downloads have completed.                                                                                               |
| No Image      | Yes            | The download was stopped because there was no firmware image present in memory.                                                                                                                                                                                                                                                      |
| Restart       | Yes            | The download was stopped due to a system restart. You must schedule a new download for any Aborted terminals.                                                                                                                                                                                                                        |
| Sys Fail      | Yes            | The download was stopped due to a system error.                                                                                                                                                                                                                                                                                      |
| Sys Occ       | No             | The download has been suspended due to the system's occupancy level. The schedule will resume when the occupancy level drops to a safe level.                                                                                                                                                                                        |
| Dnld Timeout  | Yes            | While the scheduled download was running, two or more consecutive terminals failed to respond to the download process.                                                                                                                                                                                                               |
| <b>2 of 2</b> |                |                                                                                                                                                                                                                                                                                                                                      |

**Table 132: Reason Codes for status firmware station-download 1 of 2**

| Reason Code   | Status | Description                                                                                                                              |
|---------------|--------|------------------------------------------------------------------------------------------------------------------------------------------|
| 1             | ABRT   | The firmware image that was noted on the change firmware station-download form has disappeared. The download schedule had to be stopped. |
| 2             | ABRT   | The terminal could not be downloaded due to an internal discrepancy relating to the maximum number of downloads allowed.                 |
| <b>1 of 2</b> |        |                                                                                                                                          |

**Table 132: Reason Codes for status firmware station-download 2 of 2**

| <b>Reason Code</b> | <b>Status</b> | <b>Description</b>                                                                                                                                                                                                                                                                        |
|--------------------|---------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3                  | ABRT          | The terminal was not downloaded before the scheduled stop time occurred. Schedule a new download with adequate time for the downloads to complete, or select the continue daily option to allow the schedule to resume the following day.                                                 |
| 4                  | ABRT          | The terminal could not be downloaded because the schedule aborted for an unknown reason.                                                                                                                                                                                                  |
| 5                  | ABRT          | The terminal did not respond to the download request.                                                                                                                                                                                                                                     |
| 6                  | ABRT          | The terminal that was added to the download list at the scheduled start time no longer exists. This can occur when a station is removed during an active download schedule. Download to this terminal was aborted.                                                                        |
| 18                 | ABRT          | The terminal was busied out by craft and could not be downloaded.                                                                                                                                                                                                                         |
| 32                 | ABRT          | Download to the terminal timed out due to an internal error in the station firmware download process.                                                                                                                                                                                     |
| 1000               | ABRT          | Terminal was in use at the time that it was to be downloaded. Download to this terminal was aborted.                                                                                                                                                                                      |
| 1012               | ABRT          | An internal error occurred while preparing to download to this station.                                                                                                                                                                                                                   |
| 3841               | ABRT or FAIL  | The system restarted during an active download. As a result, all terminals that were not downloaded are marked with a status of ABORT with this reason code. All terminals that were actively downloading when the reset occurred are marked with a status of FAIL with this reason code. |
| 128                | FAIL          | The terminal rejected the firmware because the firmware image failed the checksum test.                                                                                                                                                                                                   |
| 129                | FAIL          | The terminal rejected the firmware because the firmware image failed the image validity test. The firmware image may not be the right image for the hardware being downloaded to.                                                                                                         |
| 130                | FAIL          | The terminal being downloaded could not write its flash memory.                                                                                                                                                                                                                           |
| 131                | FAIL          | A terminal in the range was translated to be a valid terminal for this download schedule. However, the terminal is not a valid receiver of the download.                                                                                                                                  |
| 513                | FAIL          | The terminal was not in service at the time that it was to be downloaded. Download to this terminal failed.                                                                                                                                                                               |
| 3584               | FAIL          | The terminal rejected the firmware image.                                                                                                                                                                                                                                                 |
| <b>2 of 2</b>      |               |                                                                                                                                                                                                                                                                                           |

## GPTD-PT (General-Purpose Tone Detector Port)

| MO Name in Log | Alarm Level | Initial Command to Run             | Full Name of MO                    |
|----------------|-------------|------------------------------------|------------------------------------|
| GPTD-PT        | MAJ<br>MIN  | <code>test port location</code>    | General-Purpose Tone Detector Port |
|                | WRN         | <code>release port location</code> |                                    |

The GPTD (General-Purpose Tone Detector) ports are also known as CPTRs (Call-Progress Tone Receivers).

Tests on the GPTD port perform level measurements of test tones and detect call-progress tones. Examples of call-progress tones are dial tone, ring back, busy, alert, confirmation, and recall dial.

For Tone Detector circuit pack errors (DETR-BD), see [XXX-BD \(Common Port Circuit Pack/Media Module\)](#).

---

## Error log entries and recommended actions

**Table 133: GPTD-PT Error Log Entries**

| Error Type                | Aux Data | Associated Test                    | Alarm Level                      | On/Off Board | Recommended Action                  |
|---------------------------|----------|------------------------------------|----------------------------------|--------------|-------------------------------------|
| 0 ( <a href="#">b</a> )   | 0        | Any                                | Any                              | Any          | <code>test port location</code>     |
| 1                         | 17664    | Tone Detector Audit/Update (#43)   | MAJ<br>MIN ( <a href="#">a</a> ) | ON           | <code>test port location r 2</code> |

| 130 ( <a href="#">e</a> ) |          |                                    | WRN                              | ON           | <code>test port location r 2</code> |
| 257 ( <a href="#">c</a> ) | 17666    | Tone Detector Audit/Update (#43)   | MAJ<br>MIN ( <a href="#">a</a> ) | ON           | <code>test port location r 3</code> |
| 513 ( <a href="#">d</a> ) | Any      | Tone Detection Verification (#42)  | MAJ<br>MIN ( <a href="#">a</a> ) | ON           | <code>test port location r 3</code> |
|                           |          |                                    |                                  |              |                                     |

Notes:

- a. A Major or a Minor alarm may be logged with this error. A Major alarm is raised when the total number of GPTD ports currently in service is less than or equal to 1/2 of the threshold

number administered via **change system-parameters maintenance**. Otherwise, a Minor alarm is raised. In either case, run the short test sequence on the alarmed GPTD port and follow procedures for the individual test results.

- b. **Error Type 0**: run the short test sequence first. If every test passes, run the long test sequence. Refer to each appropriate test's description, and follow its recommended procedures.
- c. **Error Type 257**: the GPTD port lost its translation. Testing the GPTD port is sufficient to reload its translation. If testing the GPTD port does not clear the error, then replace the Tone Detector circuit pack containing the defective GPTD port.
- d. **Error Type 513**: the GPTD port is having problems detecting call-progress tones. If this error is logged constantly, replace the Tone Detector circuit pack containing the defective GPTD port.
- e. **Error Type 130**: the circuit pack has been removed or has been insane for at least 11 minutes. To clear the error, reinsert or replace the circuit pack.

---

## Demand test descriptions and error codes

Investigate tests in the order presented. By clearing errors associated with the first test, errors generated from other tests may also be cleared. Click on the link to see the full description of the test, error codes, and recommended actions.

| Order of Investigation                                 | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|--------------------------------------------------------|---------------------|--------------------|-------------------|
| <a href="#">Tone Detection Verification Test (#42)</a> | X                   | X                  | ND                |

1. D = Destructive; ND = Nondestructive

## H323-BCH (H.323 B-Channel)

No maintenance diagnostic tests exist for this maintenance object.

H.323 signaling is similar to ISDN Q.931 signaling. In order to take advantage of existing ISDN Avaya™ Communication Manager, H.323 trunk Avaya Communication Manager software includes H.323 signaling groups, H.323 D-Channels and H.323 B-Channels. H.323 signaling groups are similar in concept to ISDN PRI signaling groups. H.323 D-channels are an artificial fabrication created only to allow maximum re-use of system ISDN code. H.323 B-Channels are also an artificial fabrication.

No physical hardware components make up the H.323 B-Channel object discussed here. Along with the D-Channel, these objects allow existing ISDN Communication Manager software to be re-used for H.323 trunking. The H.323 signaling group is not a collection of physical D-channels that exist on one or more DS1 facilities. The H.323 signaling group can be considered to be one D-Channel that physically rides on a C-LAN port (IP-PROCR port in an S8300 system) and the IP network. Unlike ISDN D-channels, the H.323 D channel may come up and down on a call-by-call basis. So, the H.323 D-Channel is actually a TCP/IP signaling channel. Layer 1 and 2 of this signaling channel may be monitored by IP PING testing.

Performance in terms of voice latency for a signaling group is monitored by background measurements collected by the Media Processor board.

H.323 B-Channels use Media Processor ports to carry the actual bearer. The Media Processor port is a service circuit. On a call-by-call basis, any port of a media processor may be serving an H.323 station or an H.323 B-Channel. Status information may exist for a specific H.323 B-Channel, and an H.323 B-Channel may be busied out and released, but no maintenance diagnostic tests will exist for the object.

Errors are logged for *craft* busyout conditions. The system receives service state updates for *craft*-driven busyout/release. Under normal conditions the system automatically places H.323 B-Channels into or out of service when it receives an H.323 signaling-group service state update. *Craft* busyout drops active calls.

---

## Error log entries and recommended actions

**Table 134: H323-BCH B-Channel Error Log Entries**

| Error Type | Aux Data | Associated Test      | Alarm Level | On/Off Board | Service State |
|------------|----------|----------------------|-------------|--------------|---------------|
| 18 (a)     | Any      | B-Channel busied out | Warning     | off          | OOS           |

Note:

- a. **Error Type 18:** This specific H.323 trunk group member has been busied-out by command. Enter `release port location` to put the port in the in-service state.

---

## System Commands

The following commands are available:

- 1 **busyout port location:** on a specific H.323 B-Channel, drops any active call on that B-Channel and reduces the trunk group's capacity by one. No physical piece of hardware is removed from service.
- 1 **release port location:** on a specific H.323 B-Channel, increases the trunk group's capacity by one. No physical piece of hardware is actually added to service.
- 1 **status trunk grp#/mem#:** finds the current status of the specific B-Channel. Additional status for an H.323 B-Channel shows near- and far-end IP signaling addresses, near- and far-end H.245 addresses, tunneling status, call-reference value for an active call, and the H.323 conference ID.
- 1 **test port location:** displays No tests applicable to this object.

## H323-SGR (H.323 Signaling Group)

| MO Name in Log | Alarm Level | Initial Command to Run                 | Full Name of MO      |
|----------------|-------------|----------------------------------------|----------------------|
| H323-SGR       | MIN<br>WRN  | <code>test signaling-group grp#</code> | H323 Signaling Group |

The H.323 Signaling Group (H323-SGR) MO supports a signaling channel (D-Channel) for H.323 Trunk connections. The MEDPRO TN802 circuit pack provides audio connectivity, working in concert with a C-LAN (TN799DP) circuit pack that provides control signaling to support an H.323 connection.

The H.323 signaling group (H323-SGR) is a Signaling channel that physically resides on a C-LAN port (socket) and the IP network. Unlike ISDN D-channels, the H.323 channel may actually come up and down on a call by call basis. The H.323 channel is actually a TCP/IP signaling channel. Layers 1 and 2 of this signaling channel are monitored by IP PING testing.

---

## Error log entries and recommended actions

Table 135: H323-SGR Error Log Entries 1 of 2

| Error Type | Aux Data | Associated Test                            | Alarm Level | On/Off Board | Recommended Action                        |
|------------|----------|--------------------------------------------|-------------|--------------|-------------------------------------------|
| 0 (a)      | 0        | Any                                        | Any         |              | <code>test signaling-group grp#</code>    |
| 1 (b)      | Any      | Ethernet Port Status test (#1386)          | MIN         | OFF          | <code>test signaling-group grp#</code>    |
| 18 (c)     | 0        | <code>busyout signaling-group grp #</code> | WRN         | OFF          | <code>release signaling-group grp#</code> |
| 257 (d)    | Any      | Signaling Group Ping (#1387)               | MIN         | OFF          | <code>test signaling-group grp#</code>    |
| 513 (e)    | Any      | Signaling Group Ping (#1387)               | WRN         | OFF          | <code>test signaling-group grp#</code>    |
| 770 (f)    | Any      |                                            | WRN         | OFF          |                                           |
| 1025 (g)   | Any      | MEDPRO Status test (#1392)                 | MIN         | OFF          | <code>test signaling-group grp#</code>    |
| 1281 (h)   | Any      | MEDPRO Status test (#1392)                 | MIN         | OFF          |                                           |
| 1537 (i)   | Any      |                                            |             |              |                                           |
| 1794 (j)   |          | MEDPRO Status test (#1392)                 | MIN         | OFF          | <code>test signaling-group grp#</code>    |
| 2049 (k)   |          | Keep Alive Failure                         | MIN         | OFF          |                                           |
| 2305 (l)   |          | Gateway Unregistered Inline Error          | MIN         | OFF          |                                           |

**Table 135: H323-SGR Error Log Entries 2 of 2**

| Error Type                      | Aux Data | Associated Test                                     | Alarm Level | On/Off Board | Recommended Action |
|---------------------------------|----------|-----------------------------------------------------|-------------|--------------|--------------------|
| 2561 <a href="#">(m)</a>        | Any      | Registered to Survivable Remote Server Inline Error | MIN         | OFF          |                    |
| 2817 <a href="#">(n)</a>        |          | T303 Timer timed out                                |             |              |                    |
| 3585 <a href="#">(o)</a>        |          | Layer 3 Test (#1673)                                | MIN         | OFF          |                    |
| 3841 - 3942 <a href="#">(p)</a> | Any      |                                                     |             |              |                    |
|                                 |          |                                                     |             |              | <b>2 of 2</b>      |

Notes:

- a. **Error Type 0:** Run the short test sequence first. If every test passes, run the long test sequence. Refer to each appropriate test's description, and follow its recommended procedures.
- b. **Error Type 1:** Failure of the C-LAN hardware (IP-PROCR in S8300 systems) carrying the signaling group channel. To determine which C-LAN had been administered for this signaling group, find the near-end node name on the **signaling group** form, then find the C-LAN or IP-PROCR with the same node name on the **ip-interfaces** form.  
 Check for errors against the CLAN-BD MO.
- c. **Error Type 18:** The signaling group in question has been busied out by command. Release the signaling group, if appropriate, with **release signaling-group grp#**.
- d. **Error Type 257:** Tracks failures of the H.323 signaling-group PING test. See [Signaling Group Ping Test \(#1387\)](#) for test failure information.
- e. **Error Type 513:** Tracks excessive round-trip delay of the H.323 signaling-group PING test, if the round-trip delay exceeds 4 seconds. See [Signaling Group Ping Test \(#1387\)](#) for test failure information.
- f. **Error Type: 770:** Tracks excessive latency and packet-loss from background IP measurements collected by the Media Processor Board. Indicates that test packets sent from a media processor circuit pack to the far-end IP address specified on the signaling group form have exceeded the IP latency and loss thresholds, as administered on the **system-parameters ip-options** form. Exceeding these thresholds indicates that the IP network may not be providing sufficient quality of service for adequate transmission of voice. If the signaling group has been administered to enable BYPASS, then Error Type 1025 also occurs.
- g. **Error Type 1025:** The signaling group has been placed into a BYPASS condition because of IP network congestion. The signaling group accepts incoming calls, but every outgoing call is denied. The system routes these calls over a secondary route, if one has been administered.

- h. **Error Type 1281:** No media processor resources are in service to provide VoIP connections for the trunk members of the signaling group.

Check for errors against the MEDPRO and MEDPROPT maintenance objects. This error causes all H323 B-Channels to be in an out-of-service near-end state.

- i. **Error Type 1537:** The far end of the signaling group is not ready to handle audio bearer. If the other end of this signaling group is also a Communication Manager server, this error means the server on the other end does not have MEDPRO in-service for its signaling group.

This error places the H323 B-Channels into an out-of-service far-end state.

- j. **Error Type 1794:** The Signaling Group reported that the far end has detected excessive packet latency or loss. This error places the H323 B-Channels into an out-of-service far-end state.

- k. **Error Type 2049:** A Keep-Alive timer is set for every registered endpoint on the Remote Office, and the switch expects Keep-Alive updates within that timer's time period. If the update does not occur, an error is logged against REM-OFF as well as H323-SGR. The error against H323-SGR generates a Minor alarm. This error is only valid if the **change signaling-group** screen has the `RRQ` field set to **y**. The Keep-Alive Error Type 2049 clears only after a registration occurs and Error Type 2305 clears.

- l. **Error Type 2305:** The Gateway (signaling group on the Remote Office) is unregistered. The error against H323-SGR generates a Minor alarm when this failure occurs. This error is valid only if the **change signaling-group** screen has the `RRQ` field set to **y**.

- m. **Error Type 2561:** The signaling group is registered to a Survivable Remote Server.

- n. **Error Type 2817:** The T303 timer timed out. Notification only, no action is necessary.

- o. **Error Type 3585:** Layer 3 test failed. The far-end is not available. See [H.323 Signaling Layer 3 Test \(#1673\)](#) for more information.

- p. **Error Types 3842 - 3942:** These Error Types report certain error messages received by the H.323 Signaling Group for the D-Channel. The aux data field shows for which D-Channel the message was received.

The error code generated equals 3840+x, where "x" is a cause value. There is no recommended action for these Error Types. No direct action or alarming is performed. They provide added data that may be useful when tracking down obscure networking and routing problems. [Table 136: Descriptions and Recommendations for Error Types 3842-3942](#) provides more information.

**Table 136: Descriptions and Recommendations for Error Types 3842-3942 1 of 4**

| Error Code    | Description                                                                                                                                                                  | Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

**Table 136: Descriptions and Recommendations for Error Types 3842-3942 4 of 4**

| Error Code    | Description                                                                                                                                                         | Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|---------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3919          | Service or option not implemented, unspecified. Used when no other cause in this class applies.                                                                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| 3928          | A call was denied because of a basic incompatibility existed between the type of call and either the facilities selected by the routing pattern or the called user. | This error might be helpful as a clue if the customer complains of receiving unexpected intercept tone. Determine the trunk group from the circuit pack or media module and port number (in the Aux Data field) and then check the BCC fields of the pertinent routing patterns. Also, investigate whether or not the calling and called endpoints are compatible (for example, some switches may not allow a voice station to call a data extension). |
| 3942          | Timer expiry: T310 time-out, no answer to CALL PROCEEDING.                                                                                                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
| <b>4 of 4</b> |                                                                                                                                                                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

## Demand test descriptions and error codes

Investigate tests in the order presented. By clearing errors associated with the first test, errors generated from other tests may also be cleared. Click on the link to see the full description of the test, error codes, and recommended actions.

| Order of Investigation                                  | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|---------------------------------------------------------|---------------------|--------------------|-------------------|
| <a href="#">C-LAN Ethernet Port Status Test (#1386)</a> | X                   | X                  | ND                |
| <a href="#">MedPro Status Test (#1392)</a>              | X                   | X                  | ND                |
| <a href="#">Signaling Group Ping Test (#1387)</a>       | X                   | X                  | ND                |
| <a href="#">H.323 Signaling Layer 3 Test (#1673)</a>    | X                   | X                  | ND                |

1. D = Destructive; ND = Nondestructive

## H323-STN (H.323 IP Station)

| MO Name in Log | Alarm Level | Initial Command to Run        | Full Name of MO  |
|----------------|-------------|-------------------------------|------------------|
| H323-STN       | WRN         | <i>test station extension</i> | H.323 IP Station |

H323-STN covers implementation of the maintenance for native mode H.323 endpoints. Native mode H.323 applications such as Netmeeting or Proshare provide only what is needed to support the H.323 standard. Communication Manager can invoke very little in the maintenance area. Communication Manager reports errors as they are detected via the RAS registration and keep-alive mechanism. Communication Manager PINGs the endpoint via the signaling path, for example via C-LAN, and via the media path, for example, via Medpro.

The H.323 station type is not attached to a port board. Insertion of the station is not driven by board insertion, it is driven by successful registration of the endpoint. The H.323 station is maintained via a set of explicit TCP/IP ping requests and errors reported by the switch software, which terminates the H.323 signaling portion of each endpoint. H323-STN follows standard maintenance methodology and supports test, busyout, release and status commands.

---

## Error log entries and recommended actions

**Table 137: H323-STN Error Log Entries**

| Error Type | Aux Data | Associated Test                          | Alarm Level | On/Off Board | Recommended Action            |
|------------|----------|------------------------------------------|-------------|--------------|-------------------------------|
| 0          | 0        | Any                                      | Any         |              | <i>test station extension</i> |
| 1 (a)      |          | Registration Status Inquiry test (#1372) | WRN         | OFF          |                               |
| 257 (b)    |          | Signaling Path PING test (#1373)         | WRN         | OFF          |                               |
| 513 (c)    |          | Media Path PING test (#1374)             | WRN         | OFF          |                               |

Notes:

- a. **Error Type 1** reports the registration status of the endpoint. If Communication Manager claims the endpoint is registered and receives keep-alive handshakes from the endpoint, the test passes. If keep-alive handshaking fails, the test fails. If the user has intentionally un-registered the station from the server, the station is basically an AWOH station and is no longer being maintained; no tests will run for this station.
- b. **Error Type 257** tracks failures of the signaling path PING test. The test attempts to send a PING packet to the endpoint IP address, as reported during registration. The PING packet

originates with the C-LAN board through which the endpoint is registered. If the PING response packet is received, the test passes. If the **ping** response packet times out, the test fails.

- c. **Error Type 513** tracks failures with the media path **ping** test. The test attempts to send a **ping** packet to the endpoint IP address, as reported during registration. The **ping** packet originates with a Media Processor board. Any Media Processor board may be used as long as it is administered to be in the same network region as the C-LAN board through which the endpoint is registered. If the **ping** response is received, the test passes. If the **ping** response packet times out, the test fails.

## HYB-BD (Hybrid Line Circuit Pack)

| MO Name in Log | Alarm Level | Initial Command to Run     | Full Name of MO          |
|----------------|-------------|----------------------------|--------------------------|
| HYB-BD         | MIN<br>WRN  | <i>test board location</i> | Hybrid Line circuit pack |

See [XXX-BD \(Common Port Circuit Pack/Media Module\)](#) for circuit pack errors.

See also [HYB-LINE \(Hybrid Line\)](#) for related line information.

## HYB-LINE (Hybrid Line)

| MO Name in Log | Alarm Level | Initial Command to Run               | Full Name of MO |
|----------------|-------------|--------------------------------------|-----------------|
| HYB-LINE       | MIN<br>WRN  | <code>test port location long</code> | Hybrid Line     |

Hybrid Line is another term for the MFAT (Multi-Function Analog Telephone). The Hybrid Line set is also known as an SCS (Small Communications System).

The TN762B Hybrid Line circuit pack supports eight of these multifunction analog telephone sets. The Hybrid Line sets use three pairs of wires: an analog voice pair, a transmit/receive pair, and a power pair.

This section describes HYB-LINE (Hybrid Line) maintenance. HYB-LINE maintenance is closely related to, and sometimes interacts with, HYB-BD (Hybrid Line circuit pack) maintenance. This interaction should be kept in mind when troubleshooting Hybrid Line problems.

This section occasionally refers to a station's service state. These service states are defined as follows:

|                   |                                                                                                                                                                                                                                                                                                                                       |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Out-of-Service    | The port, and thus the station, have been removed from service. A busyout of a port will cause it to be out of service.                                                                                                                                                                                                               |
| Ready-for-Service | The port on the circuit pack has been put into service, but the voice terminal has not yet established signaling communications with the port.                                                                                                                                                                                        |
| In-Service        | The voice terminal has established signaling communications with the port, and the system is ready to process calls to and from that station. A terminal in the ready-for-service state will progress to the in-service state if it is functioning normally, but it can also be forced into the in-service state if it goes off-hook. |

Use `status station` to determine terminal service state. Status is reported as either out of service, in service, or disconnect. The latter is equivalent to the ready-for-service state.

## Error log entries and recommended actions

Table 138: HYB-LINE Error Log Entries

| Error Type     | Aux Data | Associated Test                      | Alarm Level             | On/Off Board | Recommended Action              |
|----------------|----------|--------------------------------------|-------------------------|--------------|---------------------------------|
| 0 <sup>1</sup> | 0        | Any                                  | Any                     | Any          | <i>test port location</i>       |
| 1 (a)          | 40987    |                                      | WRN                     | OFF          |                                 |
| 15 (b)         | Any      | Analog Line Audits test (#61)        |                         |              |                                 |
| 18 (c)         | 0        | <i>busyout port location</i>         | WRN                     | OFF          | <i>release port location</i>    |
| 130 (d)        |          |                                      | WRN                     | ON           | <i>test port location</i>       |

| 1793           |          | NPE Crosstalk Test (#6)              | MIN<br>WRN <sup>2</sup> | ON           | <i>test port location l r</i>   |
| 2049 (i) (j)   | 32770    |                                      |                         |              |                                 |
| 2049 (j)       | 40967    |                                      |                         |              |                                 |

1. Run the short test sequence first. If every test passes, run the long test sequence. Refer to each appropriate test's description, and follow its recommended procedures.
2. Major or minor alarms may be downgraded to Warning alarms based on the value used in the set options command.

## Notes:

- a. **Error Type 1:** The data link between the port and the terminal is not operational. (An off-board problem was detected by port circuit). Verify that the Hybrid set is connected and that the Electronic Power Feed (EPF) test passes. If data transmission problems are experienced, check for defective wiring or a defective voice terminal, or move terminal closer to the switch (reduce the length of the wiring between the terminal and the switch). If the problem persists, replace the circuit pack. Once the problem has been resolved, the alarm will be retired after a predetermined delay.
- b. **Error Type 15:** a software audit error that does not indicate any hardware malfunction. Run the short test sequence and investigate any errors.
- c. **Error Type 18:** the port is busied out. Release the port with `release port location`.
- d. **Error Type 130:** the circuit pack has been removed or has been insane for more than 11 minutes. To clear the error, reinsert or replace the circuit pack.
- e. **Error Type 257:** the EPF has been turned off due to an overcurrent condition at the voice terminal. Check for defective wiring or a damaged jack, and make sure the voice terminal is a Hybrid set. Once the problem has been resolved, the alarm will be retired after a predetermined delay.
- f. **Error Type 513:** the voice terminal has been disconnected or there is a problem in the wiring to the terminal. Make sure that the voice terminal is connected or check for defective wiring to the voice terminal.
- g. **Error Type 769 and Error Type 1281:** by themselves create Warning alarms. If both are present, a Minor alarm is logged.
- h. **Error Type 1281 or 1537:** the port has reported a problem with the data link to the voice terminal. Ignore this error if there are no complaints about the voice terminal. Otherwise, make sure the voice terminal is connected, check for defective wiring, check for a defective voice terminal, and decrease the length of the wiring between the voice terminal and the switch. If the problem persists, replace the circuit pack.
- i. The voice terminal went off-hook while in the disconnect state. Use `status station` to determine the state of the terminal. The off-hook should have moved the terminal to in service. No repair action is necessary.
- j. **Error Type 2049:** the link between the circuit pack and the voice terminal has been successfully reset. No repair action is necessary.

---

## Demand test descriptions and error codes

Investigate tests in the order presented. By clearing errors associated with the first test, errors generated from other tests may also be cleared. Click on the link to see the full description of the test, error codes, and recommended actions.

| Order of Investigation                                           | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |

1. D = Destructive, ND = Nondestructive

## INADS (INADS Link)

| MO Name in Log | Alarm Level | Initial Command to Run       | Full Name of MO |
|----------------|-------------|------------------------------|-----------------|
| INADS          | none        | <code>test inads-link</code> | INADS Link      |

The INADS Link MO represents the software and communications link used by the switch to call an alarm receiver. The purpose of the INADS Link MO is to:

- 1 Check the communications link between the system and the alarm receiver
- 1 Verify that the alarm notification process works correctly

To verify that alarms will be reported to the alarm receiver, either a centralized technician can remotely test the process, or an on-site technician can test the connection either during an installation or a subsequent service call.

Although the INADS Link MO never alarms, its errors are logged, and these errors are only logged by entering `test inads-link`.

---

## Demand test descriptions and error codes

The `test inads-link` command is different from other test commands:

- 1 There is no `long` or `short` option.
- 1 Resulting test does not have an associated test number.

When a user enters `test inads-link`, the system immediately returns either the `Command successfully completed` or `Command failed message`.

## INADS Link Test (No Test Number)

The INADS Link test attempts to call an alarm receiver (in the background) to verify the communications link with the alarm receiver. When a user enters `test inads-link`, the system immediately returns either a `Command successfully completed` or `Command failed message`.

The “Command successfully completed” message means the switch will attempt to call the alarm receiver in 2 minutes. (This test runs even if Alarm Origination is disabled.) The 2-minute delay provides enough time for a remote technician to hang up the call and thus free up the alarm receiver’s line so that the customer’s switch can call the alarm receiver back. The “Command failed” message appears when either:

- 1 A previously entered `test inads-link` is in progress
- 1 The system is attempting to report active alarms to the alarm receiver

As any error conditions are encountered during the test, they are logged against the INADS Link MO.

- 1 If the initial test result was `Command successfully completed`, any logged error codes would range from 1–9.
- 1 If the initial test result was `Command failed`, any logged error codes would be 10 or 11.

An error is logged at the alarm receiver even if the call to the alarm receiver finally succeeds. The alarm receiver’s software:

1. Recognizes this special “test inads” alarm type
2. Automatically opens and closes a trouble ticket

Within the trouble ticket, a field containing the description `TESTING INADS LINK` indicates that the ticket was initiated by `test inads-link`.

After entering the command, up to 9 minutes can elapse before the switch places the call and the alarm receiver responds. To determine whether the call was successful, the Error Log should be examined by using the `inads` category 10 minutes after successfully entering the command. [Table 139: INADS Link Test Error Log Entries](#) explains the error codes.

## IPMEDPRO (IP Media Processor)

The IPMEDPRO maintenance object applies to the TN2302 IP Media Processor and the TN2602AP IP Media Resource 320 circuit packs.

To identify which type of circuit pack is alarmed, use `list configuration board location` for the location recorded in the error log. Check the board code, then use the appropriate link below to diagnose the problem.

For the TN2302, see [IPMEDPRO \(TN2302 IP Media Processor\)](#)

For the TN2602, see [IPMEDPRO \(TN2602AP IP Media Resource 320\)](#)

## IPMEDPRO (TN2302 IP Media Processor)

If the circuit pack type is TN2602AP, see [IPMEDPRO \(TN2602AP IP Media Resource 320\)](#).

| MO Name in Log | Alarm Level | Initial Command to Run             | Full Name of MO    |
|----------------|-------------|------------------------------------|--------------------|
| IPMEDPRO       | MAJ         | <code>test board location 1</code> | IP Media Processor |
|                | MIN         |                                    |                    |
|                | WRN         | <code>test board location</code>   |                    |

The TN2302 (IP Media Processor) circuit pack is the next generation VOIP platform. The TN2302 includes a 10/100 BaseT Ethernet interface to support IP audio for IP trunks and H.323 endpoints. The TN2302 can perform echo cancellation, silence suppression, DTMF detection, and conferencing. It supports the following codecs, fax detection for them, and conversion between them:

- 1 G.711 (mu-law or a-law, 64 kbps)
- 1 G.723.1 (6.3-kbps or 5.3-kbps audio)
- 1 G.729A (8-kbps audio)

The TN2302 circuit board provides voice over IP connectivity. The TN2302 acts as a service circuit to terminate generic RTP streams which carry packetized audio over an IP network. As part of the overall H.323 implementation, the TN2302 circuit pack handles the audio streams while the TN799DP C-LAN handles the TCP/IP signaling channels.

---

| 3999 (v)   | Any      | None                            |             |              |                    |
|            |          |                                 |             |              | <b>3 of 3</b>      |

1. Run the short test sequence first. If every test passes, run the long test sequence. Refer to each appropriate test's description, and follow its recommended procedures.
2. Minor alarms on this MO may be downgraded to warning alarms based on values set in **set options**.

Notes:

- a. **Error Type 1:** the circuit pack has been removed from the system or is not fully administered. The alarm is logged about 15 minutes after the circuit pack has been removed, or 11 minutes after the SAKI test (#53) fails.

To be fully administered, an IPMEDPRO circuit pack must meet four conditions:

- 1 Have an entry in the circuit pack screen (**change circuit-pack**)
- 1 Have the MedPro IP address administered (**change node-names ip**)
- 1 Be enabled (**change ip-interface**)
- 1 Be physically inserted into the correct slot

If the circuit pack has an entry on the circuit pack screen and any of the other conditions are NOT met, a MINOR alarm is logged. To resolve the error:

- 1 Make sure every condition for administration is met, and that a functioning MedPro circuit pack is inserted in the correct slot.
- 1 Completely remove the IPMEDPRO from the system:
  - a. Remove the administered IP-Interface associated with the circuit pack.
  - b. Physically remove the circuit pack from the slot.

- b. **Error Type 18:** The IPMEDPRO interface circuit pack has been busied out by a **busyout board location** command. Release the circuit pack with **release board location**.

- c. **Error Type 23:** The IPMEDPRO circuit pack is not completely administered. To be fully administered, an IPMEDPRO circuit pack must meet **all** of these four conditions:

- 1 Have an entry in the circuit plan (**change circuit-pack**)

- 1 Have the IPMEDPRO IP address administered (`change node-names ip`)
- 1 Be enabled (`change ip-interface`)
- 1 Be physically inserted into the correct slot.

A TN2302 differs from most circuit packs in that inserting the circuit pack into the switch is not enough to make the board usable. It must also be administered.

- d. **Error Type 125:** the wrong circuit pack is inserted in the slot where this circuit pack is logically administered. Do one of the following:
  - 1 Remove the wrong circuit pack and insert the logically administered circuit pack.
  - 1 Re-administer this slot to match the circuit pack inserted (`change circuit-pack`).
- e. **Error Type 257:** failure of the Control Channel Looparound Test (#52). See [Control Channel Looparound Test \(#52\)](#) for more information.
- f. **Error Type 513:** transient hardware device problems on the board. These include an external RAM failure, internal RAM failure, ROM checksum failure, message corruption, and program logic inconsistency. If the board detects only one of these hardware problems it may be alarmed. The error will disappear when none of these faults are detected for 10 minutes. There are no associated tests for these inline errors. If they continue to happen, the circuit pack should be replaced.
- g. **Error Type 769:** failed attempts to verify IP network connectivity between a specified IP Media Processor and other IP Media Processor/s in the system. See [Short IP 2-Way Transmission Test \(#1505\)](#) for Short IP 2-way transmission test failures and [Long IP 2-Way Transmission Test \(#1506\)](#) for Long IP 2-way transmission test failures.
- h. **Error Type 770:** DSP overallocation error. Since this error causes the DSP audit to run, the condition is cleared and no action is necessary. No alarms are generated.
- i. **Error Type 1025:** Field Programmable Gate Array (FPGA) failure associated with a the FPGA device located on the TN2302. Communication Manager will take the resources associated with every DSP out of service and attempt to reset the FPGA. For the repair procedure, see [MP Diagnostic Test \(#1406\)](#)
- j. **Error Type 1281:** TSI failures. There are potentially 2 different TSI failures that can occur: one is a TSI DSP failure, and the other is a TSI FPGA failure. The switch will take the resources associated with every DSP out of service and attempt to reset the TSI. For the repair procedure, see [MP Diagnostic Test \(#1406\)](#).
- k. **Error Type 1538:** this error indicates hyperactivity on the board. Hyperactivity means the circuit pack is sending too many uplink messages to switch software. The circuit pack will be taken out of service. See (v) for Error Type 3999.
- l. **Error Type 1793:** no electrical signal is detected on the Ethernet cable. Either the Ethernet cable is unplugged or there is a problem with a connection to the network interface.
- m. **Error Type 2049:** the processor hardware is failing. The PPC provides the Angel functionality as well as the UDP/IP interface. An attempt is made to reset the board automatically. For the repair procedure, see [MP Diagnostic Test \(#1406\)](#). If the reset fails, the board is probably bad and should be replaced.

- n. **Error Type 2305:** There is an IP address inconsistency between switch software and the IPMEDPRO board. If this error occurs, an attempt will be made to download the IP address again. If the board still refuses the IP address, the board will be reset. See [IP Address Update Test \(#1371\)](#).
- o. **Error Type 2561:** the ping test has failed. See [MP Diagnostic Test \(#1406\)](#).
- p. **Error Type 2817:** Ethernet hardware failure on the TN2302 circuit pack. The switch will take resources associated with every DSP out of service and then attempt to reset the Ethernet hardware. There are several error conditions that can cause this problem. They will all be treated as the same failure by switch software. See [MP Diagnostic Test \(#1406\)](#).
- q. **Error Type 3073:** circuit board reset failed. The switch will take resources associated with every DSP out of service and then attempt to reset the board, as the failure of a Scotch is severe enough to warrant a board reset. After the reset, a query is made again for the health of the SCOTCH devices to verify whether they are working properly or not. If they are working properly, the alarm and error counters are cleared. If they are not working properly, the alarm will continue, every DSP will be left out of service, and maintenance diagnostics will stop. If the board continues to fail with this Error Type, replace the TN2302.
- r. **Error Type 3329:** an IP address update (Test #1371) was sent to the circuit pack, which detected that this IP address is a duplicate of an existing network IP address. Duplicate IP addresses can cause problems with calls on the IPMEDPRO circuit pack. It is not possible to determine where the other duplicate address is located. See the repair procedure for [IP Address Update Test \(#1371\)](#).
- s. **Error Type 3585:** The NIC parameters on the board do not match those in administration.
  - Aux Data = 1: The speed is set for auto-negotiate in administration. The board is reporting half-duplex. See the repair procedures for [Verify NIC Options Test \(#1511\)](#).
  - Aux Data = 2: The board is reporting different options than what is administered. Software tried to correct the options, but the board did not accept the option update. See the repair procedures for [Verify NIC Options Test \(#1511\)](#).
- t. **Error Type 3841:** Aux Data = None: Inconsistent downlink message. The board was sent a message it did not understand. These errors are not service affecting. No action is required.
- u. **Error Type 3841:** Aux Data = 4283: The RTCP monitor server is not connected. There is a network problem between the monitor server and the server or the RTCP monitor server is mis-administered. Use the `change system-parameters ip-options` command to verify administration of RTCP monitor server parameters.
- v. **Error Type 3999:** the circuit pack sent a large number of control channel messages to the switch within a short period of time.
  - i. If Error Type 1538 is also present, the circuit pack was taken out of service due to hyperactivity.

1. If Error Type 1538 is not present, the circuit pack has not been taken out of service, but it has generated 50 percent of the messages necessary to be considered hyperactive. This may be completely normal during heavy traffic periods. However, if this Error Type is logged when the circuit pack is being lightly used, it may indicate a problem with the circuit pack or the equipment attached to it.

---

## Demand test descriptions and error codes

Investigate tests in the order presented. By clearing errors associated with the first test, errors generated from other tests may also be cleared. Click on the link to see the full description of the test, error codes, and recommended actions.

| Order of Investigation                                   | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |

## IPMEDPRO (TN2602AP IP Media Resource 320)

If the circuit pack type is TN2302, see [IPMEDPRO \(TN2302 IP Media Processor\)](#)

See [MEDPRO-C \(Media Processor Control\)](#) for additional information on the TN2602AP IP Media Resource 320.

| MO Name in Log | Alarm Level | Initial Command to Run             | Full Name of MO       |
|----------------|-------------|------------------------------------|-----------------------|
| IPMEDPRO       | MAJ<br>MIN  | <code>test board location 1</code> | IP Media Resource 320 |
|                | WRN         | <code>test board location</code>   |                       |

The TN2602AP IP Media Resource 320 enables IP port network connectivity. The TN2602AP allows bearer traffic to be moved from the traditional Center Stage Switch (CSS) or ATM network to the IP network. Together with the TN2312BP IPSI-2 circuit pack, the TN2602AP is intended to be a traditional CSS replacement for port network connectivity.

The TN2602AP includes a 10/100 BaseT Ethernet interface to support IP audio for IP trunks and H.323 endpoints.

The TN2602AP IP Media Resource 320 provides high-capacity voice over Internet protocol (VoIP) audio access to the switch for local stations and outside trunks. The TN2602AP provides audio processing for the following types of calls:

- 1 TDM-to-IP and IP-to-TDM
- 1 IP-to-IP

See [Figure 31](#) for an example of the IP Media Resource 320 faceplate

**Figure 31: IP Media Processor faceplate**

ckdf2602 KLC 020305

The TN2602AP IP Media Resource 320 circuit pack has two capacity options, both of which are determined by the license file installed on Communication Manager:

- 1 320 voice channels, considered the standard IP Media Resource
- 1 80 voice channels, considered the low-density IP Media Resource

Up to two TN2602AP circuit packs may be installed in a single port network for load balancing. The TN2602AP circuit pack is also compatible with and can share load balancing with the TN2302 circuit pack. Actual capacity may be affected by a variety of factors, including the codec and fax support.

Actual capacity may be affected by a variety of factors, including the codec used for a call and encryption usage and the echo cancellation tail length and fax support.

---

## TN2602AP features

The TN2602AP supports hairpin connections and the shuffling of calls between TDM connections and IP-to-IP direct connections. The TN2602AP can also perform the following functions:

- 1 Echo cancellation
- 1 Silence suppression
- 1 Dual-tone multifrequency (DTMF) detection
- 1 AEA Version 2 and AES media encryption
- 1 Conferencing
- 1 802.1p and 802.Q layer 2 QoS mechanisms
- 1 RSVP protocol

The TN2602AP IP Media Resource 320 circuit pack supports the following codecs for voice, conversion between codecs, and fax detection:

- 1 G.711, A-law or Mu-law, 64 kbps
- 1 G.726A, 32 kbps
- 1 G.729 A/AB, 8 kbps audio

---

## Error log entries and recommended actions

**Table 141: TN2602AP IPMEDPRO Error Log Entries 1 of 3**

| Error Type     | Aux Data | Associated Test                        | Alarm Level | On/Off Board | Recommended Action            |
|----------------|----------|----------------------------------------|-------------|--------------|-------------------------------|
| 0 <sup>1</sup> | 0        | Any                                    | Any         | Any          | <b>test board location</b>    |
| 1 (a)          | 0        | Circuit pack removed or sanity failure | MIN         | ON           |                               |

| 3999 (y)   | Any      | None                                 |             |              |                    |
|            |          |                                      |             |              | <b>3 of 3</b>      |

1. Run the short test sequence first. If every test passes, run the long test sequence. Refer to each appropriate test's description, and follow its recommended procedures.
2. Minor alarms on this MO may be downgraded to warning alarms based on values set in **set options**.

Notes:

- a. **Error Type 1:** the circuit pack has been removed from the system or is not fully administered. The alarm is logged about 15 minutes after the circuit pack has been removed, or 11 minutes after the SAKI test (#53) fails.

To be fully administered, a TN2602AP must:

- 1 Have an entry on the circuit pack screen (**change circuit-pack**)
- 1 Have the IP Media Resource 320 IP address administered (**change node-names**)
- 1 Be enabled (**change ip-interface**)

- 1 Be physically inserted into the correct slot

If the circuit pack has an entry on the circuit pack screen and any of the other conditions are not met, a MINOR alarm is logged. To resolve the error:

- 1 Make sure every condition for administration is met, and that a functioning Media Processor is inserted in the correct slot.
- 1 Completely remove the IP Media Resource 320 from the system:
  - a. Remove the administered IP-Interface associated with the circuit pack.
  - b. Physically remove the circuit pack from the slot.

b. **Error Type 18:** The TN2602AP was busied out by a `busyout board location`.

- 1 Release the circuit pack (`release board location`).

c. **Error Type 23:** The IP Media Resource 320 is not completely administered. To be fully administered, a TN2602AP must:

- 1 Have an entry in the circuit plan (`change circuit-pack`)
- 1 Have an administered IP address (`change node-names ip`)
- 1 Be enabled (`change ip-interface`)
- 1 Be physically inserted into the correct slot.

A TN2602AP differs from most circuit packs in that inserting the circuit pack into the switch is not enough to make the board usable. It must also be administered.

d. **Error Type 125:** The wrong circuit pack is inserted in the slot where this circuit pack is logically administered. Do one of the following:

- 1 Remove the wrong circuit pack and insert the logically administered circuit pack.
- 1 Re-administer this slot to match the circuit pack inserted (`change circuit-pack`).

e. **Error Type 257:** failure of the Control Channel test (#52). See [Control Channel Looparound Test \(#52\)](#) for the repair procedures.

f. **Error Type 513:** transient hardware device problems on the board. They include an external RAM failure, internal RAM failure, ROM checksum failure, message corruption, and program logic inconsistency. There are no associated tests for these errors; if they continue to happen, an alarm will occur.

g. **Error Type 769:** failed attempts to verify IP network connectivity between a specified TN2602AP and other IP Media Processors in the system. See [Short IP 2-Way Transmission Test \(#1505\)](#) for Test #1505 failures and [Long IP 2-Way Transmission Test \(#1506\)](#) Test for #1506 failures.

h. **Error Type 770:** DSP overallocation error. Since this error causes the DSP audit to run, the condition is cleared and no action is necessary. No alarms are generated.

i. **Error Type 1025:** a module on the board failed. Aux Data values between 16641 and 16895 indicate a critical problem. See [Board Health Query Test \(#1652\)](#).

- j. **Error Type 1026:** a module on the board failed. Aux Data values between 16385 and 16639 indicate a non-critical error. See [Board Health Query Test \(#1652\)](#)
- k. **Error Type 1281:** certain firmware modules or components on the board failed to initialize properly. This test verifies that the embedded software (firmware) applications on the board are working properly. If the test fails, it is immediately run a second time. If the test fails a second time, an alarm is raised. See [Ethernet Hardware Query Test \(#1405\)](#) for more information.
- l. **Error Type 1538:** hyperactivity on the board. The circuit pack is sending too many messages to switch software. The circuit pack will be taken out of service. See (y) for Error Type 3999.
- m. **Error Type 1793:** no electrical signal is detected on the Ethernet cable. The Ethernet cable is unplugged or there is a problem with a connection to the network interface.
- n. **Error Type 2049:** There is a problem with the packet bus. See [Packet Count Query Test \(#1630\)](#).
- o. **Error Type 2305:** There is an IP address inconsistency between switch software and the IP Media Resource 320. If this error occurs, an attempt will be made to download the IP address again. If the board still refuses the IP address, the board will be reset. See [IP Address Update Test \(#1371\)](#).
- p. **Error Type 2306:** Packet link did not come up during board initialization. See the [Packet Count Query Test \(#1630\)](#) and the [IP Address Update Test \(#1371\)](#).
- q. **Error Type 2561:** the ping test has failed. The diagnostics that are run by this failure start up analysis testing and rerun the test. Testing will continue until the problem is cleared. For the repair procedure, see [Ping Test \(#1379\)](#).
- r. **Error Type 2817:** Ethernet hardware failure on the TN2602AP IP Media Resource 320. The switch takes resources associated with every DSP out of service and attempts to reset the Ethernet hardware. There are several failure conditions that can cause this error. They will all be treated as the same failure by switch software. For the repair procedure, see [Ethernet Hardware Query Test \(#1405\)](#).
- s. **Error Type 3073:** there is a problem with the Aggregator Hardware on the TN2602AP. See the repair procedure for [Aggregator Hardware Query \(#1629\)](#).
- t. **Error Type 3329:** duplicate IP address detected. Administration of the TN2602AP contains an IP address that is a duplicate of an existing network IP address. Duplicate IP addresses can cause problems with calls on the TN2602AP. It is not possible to determine where the duplicate address is located. See the repair procedure for [IP Address Update Test \(#1371\)](#).
- u. **Error Type 3330:** A virtual duplicate IP address was detected. Administration of the TN2602AP contains an IP address that is a duplicate of an existing network IP address. Duplicate IP addresses can cause problems with calls on the TN2602AP. It is not possible to determine where the duplicate address is located. See the repair procedure for [IP Address Update Test \(#1371\)](#).

- v. **Error Type 3585:** The administered NIC interface options (auto-negotiate, speed, and duplex) do not match the TN2602AP administration. On the **change ip-interface** form, if **auto** is **y**, set **speed** to **100** and **duplex** to **full**. Submit the form.
  - Aux Data = 1: The speed is set for auto negotiate in administration. The board is reporting half-duplex. See the repair procedures for [Verify NIC Options Test \(#1511\)](#).
  - Aux Data = 2: The board is reporting different options than what is administered. Software tried to correct the options, but the board did not take the option update. See the repair procedures for [Verify NIC Options Test \(#1511\)](#).
- w. **Error Type 3841:** Aux Data = None: Inconsistent downlink message. The board was sent a message it did not understand. These errors are not service affecting. No action is required.
- x. **Error Type 3841:** Aux Data = 4283: The RTCP monitor server is not connected. There is a network problem between the monitor server and the server or the RTCP monitor server is mis-administered. Use the Communication Manager administration command **change system-parameters ip-options** to verify administration of RTCP monitor server parameters.
- y. **Error Type 1538 and 3999:** the circuit pack sent a large number of control channel messages to the switch within a short period of time.
  - 1 If Error Type 1538 is also present, then the circuit pack was taken out of service due to hyperactivity.
  - 1 If Error Type 1538 is not present, then the circuit pack has not been taken out of service, but it has generated 50 percent of the messages necessary to be considered hyperactive. This may be completely normal during heavy traffic periods. However, if this Error Type is logged when the circuit pack is being lightly used, it may indicate a problem with the circuit pack or the equipment attached to it.

---

## Demand test descriptions and error codes

Investigate tests in the order presented. By clearing errors associated with the first test, errors generated from other tests may also be cleared. Click on the link to see the full description of the test, error codes, and recommended actions.

## IPSV-CTL (IP Server Interface Control)

| MO Name in Log | Alarm Level | Initial Command to Run              | Full Name of MO            |
|----------------|-------------|-------------------------------------|----------------------------|
| IPSV-CTL       | NA          | <code>set ipserver-interface</code> | Ipserver Interface Control |

The TN2312AP IPSI and TN2312BP IPSI circuit packs are duplicated in a high- or critical-reliability system. As part of duplicated IPSIs, PKT-INTs, Archangels, and Tone-Clocks are also duplicated. However, only one IPSI can be “active” in a given PN. The only exception to this rule is the IPSI’s tone-detection module. Both IPSIs may have active tone detectors.

**Note:**

The TN2312BP IPSI is a replacement for the TN2312AP IPSI and can be used anywhere a TN2312AP is used.

During an IPSI interchange, the IPSI’s PKT-INTs, Archangels, and Tone-Clocks are temporarily distributed between the two IPSIs. During stable operation, the active PKT-INT, Archangel, and Tone-Clock must all reside on the same IPSI.

**S8700-series IP-PNC:** Every PN has its own IPSI, unlike Fiber-PNC, which can share IPSI resources through the CSS/ATM network.

Each IPSI’s state of health (SOH) is based on the following elements in descending order of priority:

**Table 142: Fault classes and IPSI interchanges**

| Fault Class | Circuit pack function that is monitored                       | Priority    |
|-------------|---------------------------------------------------------------|-------------|
| Clock       | Clocking signal for the TDM bus                               | 1 (highest) |
| PKTINT      | Sending and receiving packet control messages                 | 2           |
| EAL         | Noting the state of the expansion archangel link (up or down) | 3           |
| Generation  | Generating tones                                              | 4 (lowest)  |

**Note:**

A low priority fault indicates a better state-of-health than a high priority fault. For example, a clock fault on an IPSI is more severe than a PKTINT fault on an IPSI.

The active server’s maintenance software is responsible for maintaining the SOH of both the active and standby IPSI in each PN. If an active IPSI’s SOH is lower than the standby’s, IPSI interchange is initiated. The following list contains failures and actions that cause an interchange.

Active IPSI has a faulty Tone-Clock.

1. IPSI’s hardware detects loss of clock, and its firmware initiates clock interchange.

2. IPSI's firmware notifies software of loss of clock.
3. Software interchanges Archangel.
4. Software interchanges PKT-INT.
5. The port-network is COLD started.

Active IPSI has a faulty PKT-INT.

1. Software detects faulty PKT-INT.
2. Software interchanges PKT-INT.
3. Software interchanges Archangel.
4. Software interchanges Tone-Clock.

Active IPSI has a faulty Archangel.

1. PKT-INT detects dead EAL and reports it to software.
2. Software interchanges Tone-Clock.
3. Software interchanges Archangel.
4. Software interchanges PKT-INT.

Both IPSIs are healthy (pled interchange sequence).

1. Software interchanges Tone-Clock.
2. Software interchanges Archangel.
3. Software interchanges PKT-INT.

If both of a PN's IPSIs have faulty Tone-Clock, then the PN is out of service.

If both of a PN's IPSIs have faulty EAL and/or PKT-INT, then the PN "falls back" to EI-EAL mode of operation, where:

- 1 The PN's Expansion Interface circuit pack (EI) provides Archangel functionality
- 1 Another PN's IPSI provides PKT-INT functionality

For details, see [EXP-INTF \(Expansion Interface Circuit Pack\)](#).

The following tables show the valid combinations of IPSIs and EIs providing Tone-Clock, PKT-INT, and Archangel function:

- 1 [Table 143: IPSI A is Active](#)
- 1 [Table 144: IPSI B is Active](#)
- 1 [Table 145: IPSI A Provides Tone-Clock; Fall-Back to EI-EAL](#)
- 1 [IPSI B Provides Tone-Clock; Fall-Back to EI-EAL](#)

**Table 143: IPSI A is Active**

| Function   | IPSI A | IPSI B | EI | IPSI in Another PN |
|------------|--------|--------|----|--------------------|
| Tone-Clock | X      |        |    |                    |
| PKT-INT    | X      |        |    |                    |
| Archangel  | X      |        |    |                    |

**Table 144: IPSI B is Active**

| Function   | IPSI A | IPSI B | EI | IPSI in Another PN |
|------------|--------|--------|----|--------------------|
| Tone-Clock |        | X      |    |                    |
| PKT-INT    |        | X      |    |                    |
| Archangel  |        | X      |    |                    |

**Table 145: IPSI A Provides Tone-Clock; Fall-Back to EI-EAL**

| Function   | IPSI A | IPSI B | EI | IPSI in another PN |
|------------|--------|--------|----|--------------------|
| Tone-Clock | X      |        |    |                    |
| PKT-INT    |        |        |    | X                  |
| Archangel  |        |        | X  |                    |

**Table 146: IPSI B Provides Tone-Clock; Fall-Back to EI-EAL**

| Function   | IPSI A | IPSI B | EI | IPSI in Another PN |
|------------|--------|--------|----|--------------------|
| Tone-Clock |        | X      |    |                    |
| PKT-INT    |        |        |    | X                  |
| Archangel  |        |        | X  |                    |

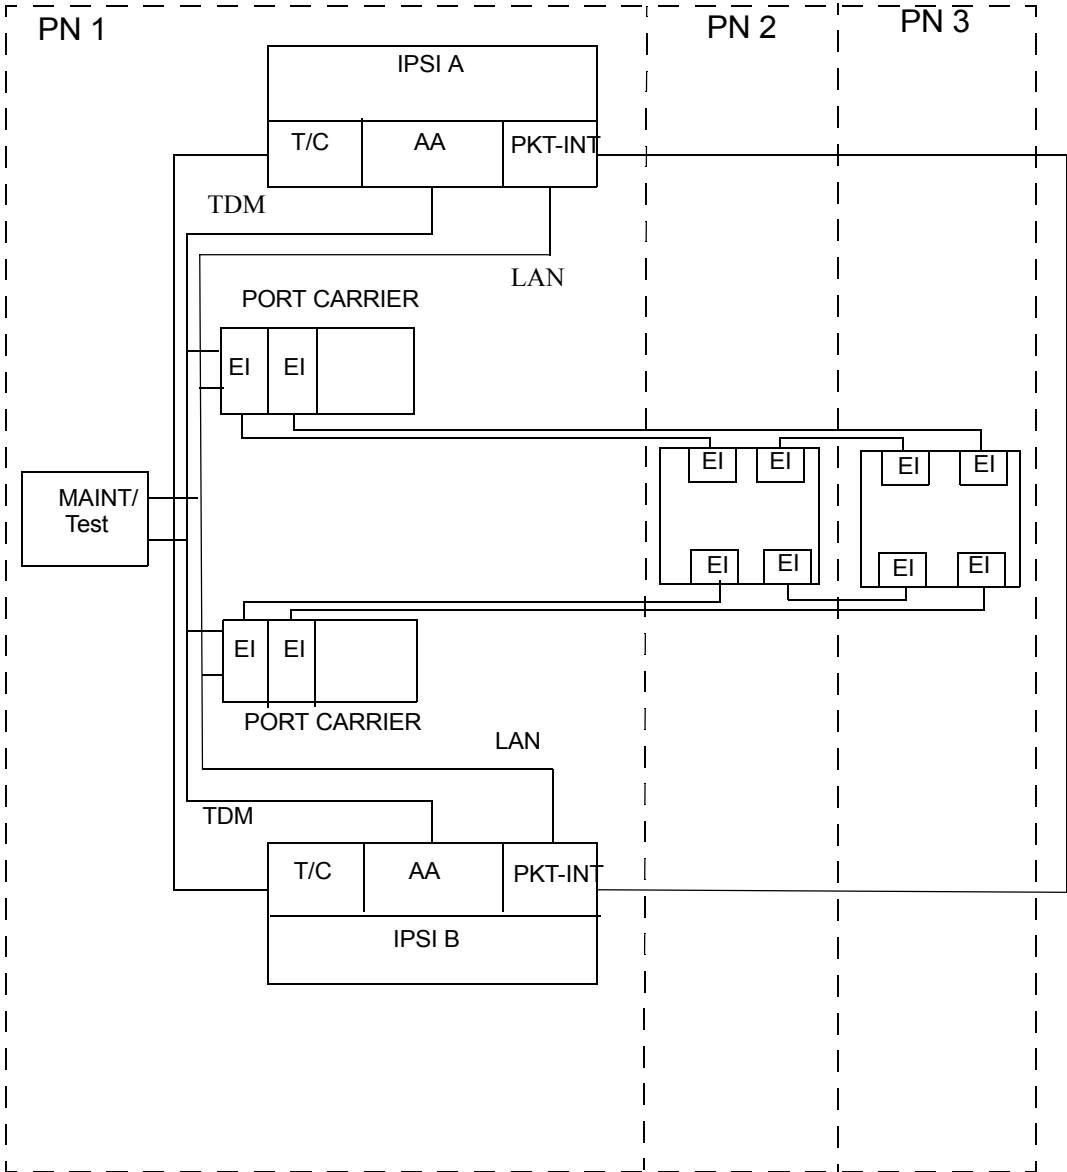

### System Configurations with Duplicated IPSIs

[Figure 32: Duplicated IPSI Duplicated Direct Connect PNC Connectivity](#) shows a critical-reliability system with duplicated IPSIs and directly connected PNCs.

[Figure 33: Duplicated IPSI Duplicated PNC with Center Stage Switch Connectivity](#) shows a critical-reliability system with duplicated IPSIs and CSS-connected PNCs.

[Table 147: Cabinets that support IPSI and IPSI duplication](#) shows a complete list of cabinets.

**Figure 32: Duplicated IPSI Duplicated Direct Connect PNC Connectivity**

**Figure 33: Duplicated IPSI Duplicated PNC with Center Stage Switch Connectivity**

**Table 147: Cabinets that support IPSI and IPSI duplication**

| Cabinet type     | Supported IPSI |          | Duplication  |                |
|------------------|----------------|----------|--------------|----------------|
|                  | TN2312AP       | TN2312BP | Primary slot | Secondary slot |
| SCC1 EPN Stack   | Y              | Y        | A00          | B01            |
| MCC1 EPN - 1 PN  | Y              | Y        | A00          | B01            |
| MCC1 EPN - 2 PNs | Y              | Y        | A00          | B01            |
|                  |                |          | E02          | D01            |

|                  |                |          | D02          | N/A            |
|                  |                |          | E02          | N/A            |
| G600             | Y              | Y        | A02          | N/A            |
| CMC1 PN          | N              | Y        | A02          | N/A            |
| G650 Stack       | N              | Y        | A01          | B01            |
|                  |                |          |              |                |

## Error Log Entries

Whenever an IPSI interchange takes place, an error is logged against IPSV-CTL with a code that conveys information about the cause of the interchange and which IPSI became active.

See the following tables to identify areas of the Alarm Log to help find the source of the problem:

- 1 [Encoding of Error Codes for Software Requested IPSI interchange](#)
- 1 [Aux Data Descriptions for Software-Requested Interchange](#),
- 1 [Error codes for set ipserver-interface](#)

**Table 148: Error Code Descriptions and Aux Data**

| Error Code         | Description                                                       | Aux Data                      |
|--------------------|-------------------------------------------------------------------|-------------------------------|
| 3wxyz <sup>1</sup> | Software requested IPSI interchange / control change <sup>2</sup> | See <a href="#">Table 150</a> |
| 50000              | Craft demand interchange of IPSI to A side                        | See <a href="#">Table 150</a> |
| 51000              | Craft demand interchange of IPSI to B side                        | See <a href="#">Table 150</a> |
| 60000              | Daily interchange of IPSI to standby failed                       | 0                             |
| 61000              | Daily interchange of IPSI back to previous active failed          | 0                             |

1. See [Table 149](#) for encoding of the wxyz digits of the error code.

2. Control change is moving the Archangel's functionality to or from the IPSI.

## Error Codes for Software-Requested Interchanges

**Table 149: Encoding of Error Codes for Software Requested IPSI interchange 1 of 2**

| Field | Variable Name           | Value | Description                                      |
|-------|-------------------------|-------|--------------------------------------------------|
| w     | Active IPSI post action | 0     | The A-side IPSI is active after the interchange. |
|       |                         | 1     | The B-side IPSI is active after the interchange. |

**1 of 2**

**Table 149: Encoding of Error Codes for Software Requested IPSI interchange 2 of 2**

| Field | Variable Name                                      | Value | Description                                             |
|-------|----------------------------------------------------|-------|---------------------------------------------------------|
| x     | Control (Archangel)<br>pre and post action         | 0     | Control on IPSI before and after the interchange.       |
|       |                                                    | 1     | Not in IPSI control before and after the interchange.   |
|       |                                                    | 2     | Control leaves IPSI.                                    |
|       |                                                    | 3     | Control moves to IPSI.                                  |
| y     | Fault class/stimulus<br>causing software<br>action | 1     | EAL fault class                                         |
|       |                                                    | 2     | PKT-INT fault class                                     |
|       |                                                    | 3     | TONE-BD fault class (not TDM-CLK)                       |
|       |                                                    | 4     | TDM-CLK fault class (loss of clock)                     |
|       |                                                    | 7     | Preference migration to A-side IPSI                     |
| z     | Fault or<br>improvement                            | 0     | This is an improvement in the previous fault class (y). |
|       |                                                    | 1     | This is a degradation of the previous fault class (y).  |
|       |                                                    |       | <b>2 of 2</b>                                           |

## AUX Data Descriptions

**Table 150: Aux Data Descriptions for Software-Requested Interchange**

| Aux Data | Description                                              |
|----------|----------------------------------------------------------|
| 0        | No specific extra information is available               |
| 1        | An IPSI interchange only took place                      |
| 2        | A control change only took place                         |
| 3        | Both an IPSI interchange and a control change took place |

### Examples:

Error Code of 30320 with Aux Data 2 software requested the archangel move to the A-side IPSI as a result of a PKT-INT fault class improvement.

Error Code of 31041 with Aux Data 1 indicates a software requested interchange from the A-side IPSI to the B-side IPSI leaving the archangel on the IPSI due to a loss of TDM clock.

---

## IPSI Interchange (Duplicated IPSIs)

Software will take action upon any fault that affects the IPSI and attempt to interchange to the healthier IPSI. In addition, when neither IPSI is completely healthy to provide clock, packet interface and archangel, one IPSI will be chosen to be the clock, and the archangel will move to the EI. Moving the archangel's functionality to the EI requires another port network to have a healthy IPSI, and this port network to have an EI. The exact order of action taken will vary depending on the fault being processed, as well as the existing state of health (SOH) of the IPSIs in the PN. An IPSI interchange (if necessary) will always happen before a control change (moving of the archangel to/from IPSI/EI). If both IPSIs are equally healthy, software preferentially migrates to the A-side IPSI. However, this preferential migration is not done if craft has set to a B-side IPSI.

Craft can also demand an interchange of IPSIs in one or every PN. The command `set ipserver-interface Uc` interchanges a specific IPSI. In addition, `set ipserver-interface a-all | b-all` can be used to interchange every IPSI in the system to the A-side or B-side respectively. This is particularly useful if preparing for a control-network outage. For a pled interchange of IPSIs, the following steps occur. The:

1. Going active IPSI is marked as active, the going standby is marked as standby.
2. Tone-Clock is migrated. This includes tone generation as well as TDM clock.
3. Archangel is migrated to the newly active IPSI.
4. PKT-INT on the newly active IPSI is made active. Every link is migrated between IPSIs.

See [Table 151: Error codes for set ipserver-interface](#) for ABORT/FAIL codes associated with `set ipserver-interface`:

**Table 151: Error codes for set ipserver-interface**

| Error Code | Command Result | Description                                                                                                                                                                                     |
|------------|----------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2343       | ABORT          | Interchange not permitted. The anti-thrashing timer has not yet expired.<br><ol style="list-style-type: none"><li>1. Retry command in 30 seconds.</li></ol>                                     |
| 2338       | FAIL           | The SOH of the set-to IPSI is bad. Use <code>list ipserver-interface</code> to display the current IPSI's SOH.                                                                                  |
| 2341       | FAIL           | An error occurred during the interchange. This indicates an internal problem. Use <code>list ipserver-interface</code> to see if the interchange actually occurred.                             |
| 2342       | FAIL           | The set-to IPSI has been busied out.<br><ol style="list-style-type: none"><li>1. Run <code>release ipserver-interface Uc</code>.</li></ol>                                                      |
|            | PASS           | The interchange was successful, or the set to IPSI was already active. If set to a B-side IPSI, it will be marked as "craft set" and will not preference switch back to the A-side by software. |

An example of the output of the `list ipserver-interface` command is:

```
list ipserver-interface
```

| IP SERVER INTERFACE INFORMATION |                 |                               |                              |                            |            |               |                         |  |

The **State of Health** information contains the fault class information in the far right columns as follows:

- 1 C = Clock
- 1 P = Packet Interface
- 1 E = Expansion Archangel Link
- 1 G = Tone Generation

# IP-SVR (IP Server Interface)

S8700 Series S8400| S8500

| MO Name in Log | Alarm Level | Initial Command to Run                                                             | Full Name of MO     |
|----------------|-------------|------------------------------------------------------------------------------------|---------------------|
| IP-SVR         | WRN         | <code>busyout ipserver-interface</code><br><code>release ipserver-interface</code> | IP Server Interface |

There are three IP Server Interface (IPSI) circuit packs:

- | TN2312 IP Server Interface Circuit Pack
- | TN2312BP IP Server Interface Circuit Pack
- | TN8412AP S8400 IP Server Interface Circuit Pack (SIPI)

**Note:**

The TN8412AP is the same as the TN2312BP, except that it can only run in an S8400 system.

The IP Server Interface (IPSI) circuit packs report the following settings to Communication Manager:

- | 802.1p value
- | DiffServ value
- | Ethernet auto-negotiate
- | Ethernet Duplex
- | Ethernet Speed

Communication Manager compares the values of these settings with the Communication Manager administered values and raises an alarm if discrepancies are found. This alarm is reported against MO\_IPSI\_BD with an Error Type of 1.

---

## TN2312 IP Server Interface Circuit Pack

**Note:**

The only Error Type reported against this MO is error Type 18. All other Error Types will be reported against MOs supporting the IPSI circuit pack functional modules: PKT-INT, IPSV-CTL, ETR-PT, TDM-CLK, TONE-PT, TONE-BD, SER-BUS, CAB-EXFR, EXT-DEV, CAB-PFL, POW-SUP, CAB-TEMP, PS-RGEN, CAB-CALM, and CAB-MTCE.

The TN2312 IPSI circuit pack connects the port networks to the servers via an IP network and provides port-network control functions.

The TN2312 IPSI is inserted into the PN's Tone-Clock slot and provides interface back to the servers via the Ethernet. The IPSI circuit-pack provides the following functions:

- 1 PKT-INT packet bus interface
- 1 Archangel TDM-bus interface
- 1 Tone-Clock functionality (equivalent to TN2182C Tone-Clock circuit pack)
- 1 Ethernet interface for connectivity to the servers
- 1 Ethernet interface for connectivity to Services' laptop PCs
- 1 Maintenance-board interface for communication with the PN's TN775 Maintenance board (TN2312AP)
- 1 Environmental maintenance (TN2312BP)

The processors, and the PKT-INTs reside in different cabinets, connected to each other via the control networks. All communication between the servers and the IPSIs are done over TCP/IP Socket connections. Other than the Ethernet that connects the servers to the IPSIs, there are no other leads for signaling and resets. All communication between the servers and the IPSIs must be done via messages over the socket connections.

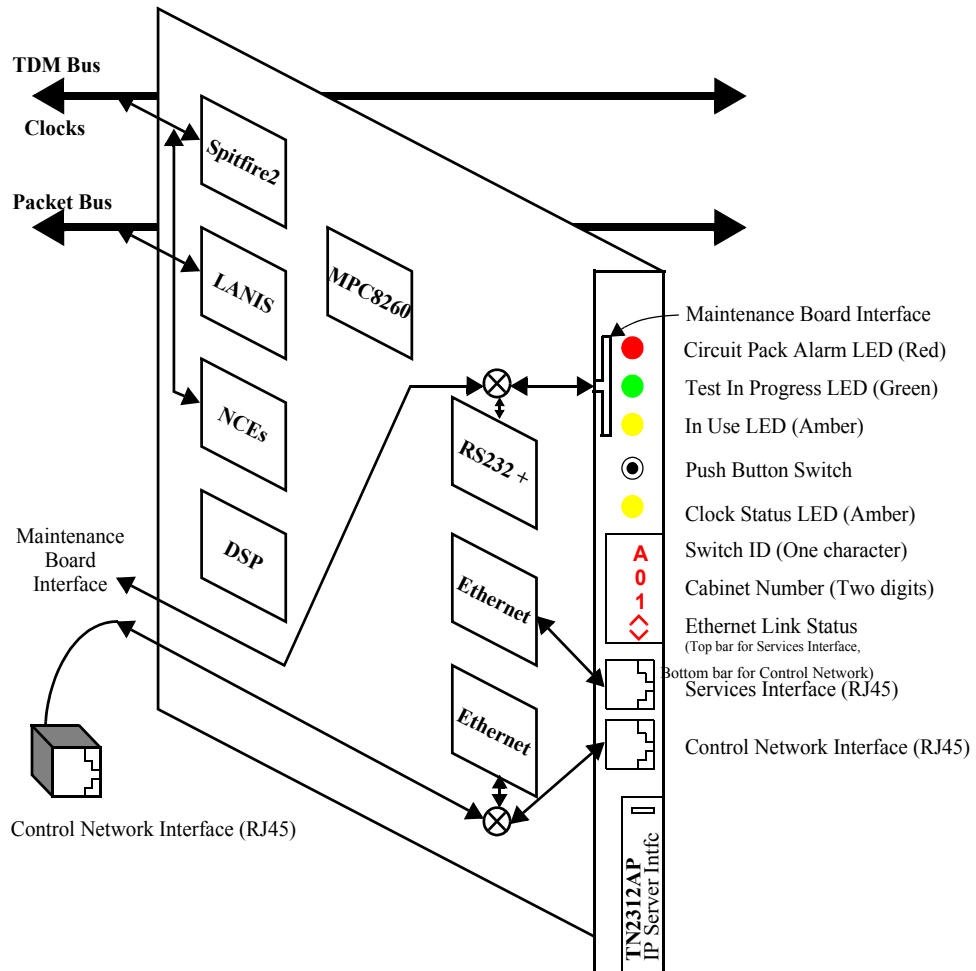

Each IPSI's state of health (SOH) is kept with the following elements in descending order of priority:

**Table 152: IPSI state-of-health components**

| <b>Fault Class</b> | <b>Circuit pack function that is monitored</b>                | <b>Priority</b> |
|--------------------|---------------------------------------------------------------|-----------------|
| Clock              | Clocking signal for the TDM bus                               | 1 (highest)     |
| PKTINT             | Sending and receiving packet control messages                 | 2               |
| EAL                | Noting the state of the expansion archangel link (up or down) | 3               |
| Generation         | Generating tones                                              | 4 (lowest)      |
|                    |                                                               |                 |

# TN2312AP IP Server Interface (IPSI)

Figure 34: TN2312AP IPSI

## Control Network Interface

This is a 10/100 BaseT Ethernet interface used to connect to the Control network. This interface is available through the backplane I/O as well as through the faceplate. When the IPSI I/O adapter is plugged onto the Amphenol connector, located on the rear of the carrier, the backplane connections will be selected, otherwise, connectivity to the faceplate will be selected. For the PN control carriers, the backplane connections are available only when the new PN control carriers are used.

## Services Interface

This is a 10/100 BaseT Ethernet interface accessible from the faceplate for services personnel to configure the IPSI firmware (IP address settings), access the SAT, and to debug the control network connectivity (ping, traceroute, etc.).

## PN's Maintenance Board Interface (TN2312AP)

This interface consists of RS232 transmit and receive leads and reset leads that connect to the PN's TN775D Maintenance board via the faceplate or the backplane. Communication Manager talks to the Maintenance board via the IPSI's archangel through this interface for cabinet maintenance (cabinet temperature, voltage, emergency transfer and etc.). This interface also allows the Maintenance board to reset the IPSI board when it detects insanity of the IPSI's archangel. When the ribbon cables are connected between the IPSIs and the PN's TN775D Maintenance board, the faceplate connections are selected, otherwise the backplane connections are used. The backplane connections are available only when the new backplane is used. This connection will not support the RS-232 SAT connection via the PN's Maintenance board.

## Environmental maintenance (TN2312BP)

The TN2312BP IP Server Interface (IPSI) provides environmental maintenance and is the only IP server interface that is supported in the G650. A TN2312BP can only be placed in a G650 with a carrier address set to A or B. Only a TN2312BP in a G650 with a carrier address set to A provides environmental maintenance. The TN2312BP is backward compatible with the TN2312AP, but provides environmental maintenance only when used in a G650. The TN2312BP always provides tone detection, call classification, tone generation, and clock functions.

When the TN2312BP is used in an MCC1 or SCC1, a TN775D provides the environmental maintenance.

The TN2312BP provides environmental maintenance for the G650. This includes:

- 1 External device alarm detection
- 1 Emergency transfer control
- 1 Customer-provided alarm device control

The TN2312BP and the 655A power supply provide the following information to the G650:

1 **Environment maintenance**

- Inlet temperature - Inlet temperature of the G650 (sensor is in the 655A power supply)
- Exhaust temperature - G650 carrier exhaust air sensor
- Hot Spot temperature status- 655A power supply sensor
- Voltage
  - +5VDC
  - -5VDC
  - -48VDC
- Fan Control - The speed at which the fans are operating:
  - Under indicates that the fan voltage is under 12VDC.
  - Mid (normal) indicates that the fan voltage is +12VDC.
  - High indicates that the fan voltage is +14VDC.
  - Over indicates that the fan voltage is above 14 to 15VDC.
- Fan Alarm - Detection of a blocked or failed fan
- Ring Status - OK, overload, shorted, or failed
- Ring Control - Active, standby, disabled, off (shorted or failed)
- Ringer Setting - 20Hz, 25Hz, or other
- Ring Detection - Reports if the power supply detects ring on the backplane ring leads
- Input Power - Indicates the type of power present and in use, AC or DC

1 **External device alarm detection**

The external device alarm detection uses two external leads. External devices such as an uninterruptible power supply (UPS) or voice messaging system can use these leads to generate alarms using the Communication Manager alarm reporting capability. Ground potential on either of these leads results in an alarm being generated. The alarm level (major, minor, or warning), product ID, alternate name, and alarm description can be administered for each lead.

1 **Emergency transfer control**

Emergency transfer control provides -48VDC to operate an external emergency transfer panel. The Communication Manager controls the state of the emergency transfer. (Note that, in the past, hardware boards or alarm panels provided a three-position physical switch to control emergency transfer.) An emergency transfer status red LED shows when emergency transfer is active.

The following Communication Manager SAT commands can be used for emergency transfer:

- `set emergency-transfer on|off|auto` - Use this to set emergency transfer to `on` (not in emergency transfer), `off` (in emergency transfer), or `auto` (emergency transfer is controlled by Communication Manager).
- `status cabinet nn` - Use this to verify the current setting of emergency transfer.

When the emergency transfer is set to other than `auto` an alarm is generated.

#### 1 **Customer provided alarm device (CPAD) control**

CPAD provides a contact closure across a pair of external leads that can be used to control a customer-provided alarm device or an alarm indicator. The level of alarm (major, minor, warning, or none) that causes a contact closure can be administered system wide. When the alarm level matches the alarm level that was administered, the TN2312BP closes this contact. When the TN2312BP is in emergency transfer, this contact is closed to activate the CPAD.

#### 1 **Tone Detection / Call Classification**

The TN2312BP provides eight ports of tone detection and call classification. The TN2312AP provides the same functionality.

#### 1 **Tone/Clock functions**

The TN2312BP generates tones and provides clock functions for the port network in which it is placed. (The TN2312AP provides the same functionality.) This functionality is equivalent to the TN2182B Tone/Clock circuit pack.

### **TDM-Bus Interface**

The TDM bus is used by four different functions on the IPSI board:

1. When the Archangel module is activated, it uses the Spitfire2 device to be the bus master of the TDM bus. The Archangel uses this interface to talk to the other port boards' angels on the TDM bus.
2. In Angel mode, the Tone-Clock Angel uses the Spitfire2 device to talk to an off-board Archangel.
3. The Tone Generator uses the Spitfire2 device to put tones on the TDM bus.
4. The Tone Detector uses the NCE device to receive TDM bus time slots for tone detection.

### **Packet Bus Interface**

When the PKT-INT module is activated, it uses the LANIS device to talk and listen on the packet bus.

### **System Clock Interface**

The Clock module uses the Spitfire2 device to generate clock pulses for the backplane.

## IPSI Circuit Pack Faceplate

The faceplate view of the TN2312AP IPSI is shown in [Figure 34: TN2312AP IPSI](#) and is described in the following sections.

### IPSI LEDs

There are four LEDs on the TN2312AP IPSI faceplate, and five LEDs on the TN2312BP IPSI and TN8412AP SIPI (S8400 IP Interface) faceplate. The top three are the standard LEDs found on most TN circuit packs. The fourth LED indicates that the Tone-Clock function is active and imitates the TN2182B Tone-Clock's amber LED. In addition, the TN2312BP and TN8412AP have a fifth LED that shows the emergency transfer control status. [Table 153: IPSI LEDs](#) describes the operation of the IPSI's LEDs.

**Table 153: IPSI LEDs 1 of 2**

| Function                     | LED   | State                               | Description                              |
|------------------------------|-------|-------------------------------------|------------------------------------------|
| Standard circuit pack status | Red   | On                                  | Power up in progress or alarm is present |
|                              | Green | On                                  | Test in progress                         |
|                              | Amber | Off                                 | Circuit pack not in use                  |

|                                                   |       | Steady off                                                                                                     | Standby: Applying no tones to the network.                                                                         |
|                                                   |       | “Jingle Bells”<br>Green and Amber<br>0.1 sec on, 0.2 sec off, 0.1 sec on, 0.4 sec off, 0.4 sec on, 0.4 sec off | Standby: Tone generator is being used.                                                                             |
|                                                   |       | Double blink<br>Amber 0.3 sec on, 0.3 sec off, 0.3 sec on, 2.4 sec off                                         | Active: Lost all external references and is in holdover mode.                                                      |
|                                                   |       | Random                                                                                                         | Standby: This LED may come on and off intermittently as ETR-PTs on the board are used for tone-detection services. |
| Emergency transfer<br>(TN2312BP)                  | Red   | On                                                                                                             | Emergency transfer is active.                                                                                      |
|                                                   |       | Off                                                                                                            | Emergency transfer is inactive.                                                                                    |
|                                                   |       |                                                                                                                | <b>2 of 2</b>                                                                                                      |

### Push-Button Switch

The push-button switch is used to administer the switch ID and the cabinet number of the IPSI. This button can also be used to erase the manually programmed IP address. Inserting the IPSI board with the button pressed or just resetting it while the button is pressed will keep the IPSI in boot mode.

## 4-Character LED

The 4-character LED displays the circuit pack status related to the Ethernet interfaces. If automatic IP address assignment via DHCP is enabled, the top character displays the Switch ID and the next two characters display the Cabinet Number. The last character is used to display the link status of the two Ethernet interfaces.

## Services Interface

The top RJ45 jack is the services interface. This is a 10/100 BaseT Ethernet interface.

## Control Network Interface

The bottom RJ45 jack is the control network interface. This is a 10/100 BaseT Ethernet interface. This interface is active only when the IPSI I/O adapter is not plugged onto the Amphenol connector, located on the rear of the carrier.

## PN's Maintenance Board Interface

The PN's Maintenance board interface is a header on the IPSI circuit pack with a slit on the faceplate of the IPSI for the ribbon cable to connect to the PN's TN775D Maintenance board.

## Demand tests descriptions and error codes

There are no demand tests for IP-SVR.

## ISDN-PLK (ISDN-PRI Signaling Link Port)

| MO Name in Log | Alarm Level | Initial Command to Run <sup>1</sup> | Full Name of MO              |
|----------------|-------------|-------------------------------------|------------------------------|
| ISDN-PLK       | MIN         | <code>test port location 1</code>   | ISDN-PRI Signaling Link port |
|                | WRN         | <code>test port location</code>     |                              |

1. *location* refers to the port board location and port number. The port number is either **24** for 24-channel interfaces or **16** for 32-channel interfaces.

This MO was formerly known as “ISDN-LNK (ISDN-PRI Signaling Link Port)”.

**Note:**

See the figures in [ISDN-SGR \(ISDN-PRI Signaling Group\)](#) for an illustration of the principles described below.

The ISDN-PRI interface uses out-of-band signaling (as opposed to robbed-bit, in-band signaling) to transmit control messages between two endpoints. User information channels carry digitized voice and digital data and are known as bearer channels (B-Channels). B-Channels are assigned to DS1 ISDN trunks or PRI endpoints. Call-control signaling for the B-Channels is combined and carried over the separate ISDN-PRI Signaling Link Port D-Channel.

The ISDN-PRI Signaling Link Port (ISDN-PLK) is a port on a TN464C or higher suffix UDS1 Interface circuit pack that has a direct interface to the packet bus that carries D-channel messages to the processor. The associated B-Channels can use ports on the same circuit pack or ports on other TN464C or higher suffix or TN767 DS1 Interface circuit packs. The TN722 cot be used for this application. The B-Channels are connected to the TDM Bus.

Two types of DS1 interfaces exist:

- 1 24 DS0 channels on a 1.544-Mbps link
- 1 31 DS0 channels + 1 framing channel on a 2.048-Mbps link

The TN767 DS1 interface is used for 24 channel 1.544 Mbps systems. The TN464F/GP can be used for either 24 or 32 channel systems. The 32-channel (31 DS0 channels + 1 framing channel on a 2.048 Mbps link) are only supported on TN464 series circuit packs. A description of these circuit packs appears in DS1-BD or UDS1-BD maintenance documentation.

On 24-channel interfaces, the B-Channels may use any of the first 23 ports. The signaling link is assigned to the 24th port.

On 32-channel interfaces, the DS1 ISDN Trunks (B-Channels) may use any of the ports 1 to 15 and 17-31. The signaling link is assigned to the 16th port. The 32nd channel (port 0) is used for framing.

In NFAS configurations, the 16th or 24th ports on some of the DS1 circuit packs may be used for B-Channels. Refer to [ISDN-SGR \(ISDN-PRI Signaling Group\)](#) for further details.

A problem with the ISDN-PLK will affect every associated B-Channel since no call control information can be conveyed to the far-end switch or terminal adapter. Stable calls may remain operational, but no new calls can be placed. In turn, the ISDN-PLK depends on:

- 1 For systems supporting circuit packs:
  - 1 the UDS1 Interface circuit pack where it resides
  - 1 the packet bus that provides the link to the processor
- 1 For systems supporting media modules:
  - 1 the DS1 Interface Media Module that provides the link to the processor

If there are problems with the ISDN-PLK, also investigate [UDS1-BD \(UDS1 Interface Circuit Pack\)](#) and [PKT-BUS \(Packet Bus\)](#) for systems supporting circuit packs, or investigate [MG-DS1 \(DS1 Interface Media Module\)](#) for systems supporting media gateways.

## Error log entries and recommended actions

**Table 155: ISDN-PLK Error Log Entries**

| Error Type                 | Aux Data | Associated Test                          | Alarm Level | On/Off Board | Recommended Action                       |
|----------------------------|----------|------------------------------------------|-------------|--------------|------------------------------------------|
| 0 ( <a href="#">a</a> )    | 0        | Any                                      | Any         | Any          | <i>test port location<sup>1</sup></i>    |
| 18 ( <a href="#">b</a> )   | 0        | <i>busyout port location<sup>1</sup></i> | WRN         | OFF          | <i>release port location<sup>1</sup></i> |
| 130 ( <a href="#">c</a> )  |          |                                          | WRN         | ON           | <i>test port location<sup>1</sup></i>    |

| 1793 ( <a href="#">e</a> ) |          |                                          |             |              | <i>test board location 1</i>             |
| 3585 ( <a href="#">f</a> ) | 46222    |                                          | MIN         | ON           |                                          |
| 3841 ( <a href="#">g</a> ) | 46211    |                                          |             |              |                                          |
| 3842 ( <a href="#">h</a> ) | 46223    |                                          |             |              |                                          |
| 3843 ( <a href="#">i</a> ) |          | Signaling Port LAN Loopback (#939)       |             |              | <i>test port location<sup>1</sup> 1</i>  |

1. location is **24** for 24-channel interfaces and **16** for 32-channel interfaces.

Notes:

- a. **Error Type 0:** run the short test sequence first. If every test passes, run the long test sequence. Refer to each appropriate test's description, and follow its recommended procedures.

- b. **Error Type 18:** The D-Channel is demand busied out by command. No calls can be made over this D-Channel.
- c. **Error Type 130:** the circuit pack or media module has been removed or has been insane for more than 11 minutes. To clear the error, reinsert or replace the circuit pack or media module.
- d. **Error Type 1537:** Link error. This error occurs when the port receives an invalid frame over the D-Channel. This error normally indicates an off-board problem usually related to transmission errors on the DS1 facility. Enter `list measurements ds1-log` for the UDS1 TN464 circuit pack or DS1 Media Module where the D-channel resides. If the UDS1 or MG-DS1 is reporting errors, the DS1 facility has experienced transmission problems that could have caused the ISDN-PLK to report a Link Error.
- If the UDS1 or MG-DS1 is not reporting errors, execute the long test sequence for the D-Channel. Investigate any errors. If there are none, execute a long test sequence for the UDS1 circuit pack (UDS1-BD) or DS1 Media Module (MG-DS1). Investigate any errors.
- If no errors could be found by testing, the Link Error is probably not affecting service. However, if this Link Error continues to be logged, follow normal escalation procedures.
- e. **Error Type 1793:** UDS1 Interface circuit pack or DS1 Interface Media Module is out of service. Look for and resolve UDS1-BD or MG-DS1 errors in the Hardware Error Log.
- f. **Error Type 3585:** transmit FIFO Overflow error. The circuit pack is having problems transmitting data to the packet bus, thus affecting the conveyance of signaling information over the D-Channel. Specifically, this error occurs when the packet bus transmit buffers overflow. This condition probably indicates a hardware problem.
- The actual alarming level will depend on the options chosen via the `set options` command. ISDN-PRI Signaling Link port alarms are treated as Station alarms, and their default alarming option is to downgrade every alarm to Warning. The value shown in the preceding table indicates the normal, unfiltered case (option "y" on the `set options` screen).
- g. **Error Type 3841:** Bad DLCI error. This error occurs when a LAPD frame is received across the DS1 facility that contains a DLCI that does not have a valid entry in the on-board translation memory. This error normally indicates an off-board problem usually related to a broken endpoint or a state mismatch between a remote endpoint and the local call-processing software. Maintenance will not start any testing or generate any alarms in response to this error.
- h. **Error Type 3842:** Receive FIFO Overflow error. This error occurs when the circuit pack or media module detects an overflow of its receive buffers. If it occurs frequently, it may indicate a LAPD parameter mismatch between the two endpoints of a packet-switched connection. LAPD should be able to recover from this problem, but it may degrade the performance of the LAN bus. Maintenance will not start any testing or generate any alarms in response to this error.
- i. **Error Type 3843:** The Signaling Port LAN Loopback test (#939) failed. Run the long test sequence and note the results of the [Signaling Port LAN Loopback Test \(#939\)](#).

---

## Demand test descriptions and error codes

The command to test the ISDN-PLK MO is `test port location` where *location* is the port board location and either **24** for 24-channel interfaces or **16** for 32-channel interfaces. For example, `test port 8E0524`.

| Order of Investigation                                  | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|---------------------------------------------------------|---------------------|--------------------|-------------------|
| <a href="#">Signaling Link Board Check (#643)</a>       | X                   | X                  | ND                |
| <a href="#">Signaling Port LAN Loopback Test (#939)</a> |                     | X                  | D                 |

1. D = Destructive; ND = Nondestructive

## ISDN-SGR (ISDN-PRI Signaling Group)

| MO Name in Log | Alarm Level | Initial Command to Run <sup>1</sup>    | Full Name of MO          |
|----------------|-------------|----------------------------------------|--------------------------|
| ISDN-SGR       | MIN<br>WRN  | <code>test signaling-group grp#</code> | ISDN-PRI Signaling Group |

1. *grp#* is the signaling group number (1–166); the test sequence can be either short or long.

An ISDN-PRI Signaling Group is a collection of B-Channels for which a given ISDN-PRI Signaling Channel Port (D-channel) carries signaling information. B-Channels carry voice or data and can be assigned to DS1 ISDN trunks (ISDN-TRK) or PRI endpoint ports (PE-BCHL).

**Note:**

Throughout this discussion, the term “B-Channel” refers to an ISDN-TRK or PE-BCHL, depending on the application under investigation.

The following circuit packs/media modules are supported in the implementation of ISDN-PRI:

| Circuit Pack/<br>Media Module | Channel Types     | Interface        |
|-------------------------------|-------------------|------------------|
| MM710                         | B- and D-Channels | 24 or 32 channel |
| TN464B                        | B-Channels        | 32 channels      |
| TN464C/D/E                    | B- and D-Channels | 24 or 32 channel |
| TN464F/GP/HP                  | B- and D-Channels | 24 or 32 channel |
| TN767                         | B-Channels only   | 24 channels      |

. There are two types of DS1 interfaces:

- 1 24 DS0 channels on a 1.544-Mbps link
- 1 31 DS0 channels + 1 framing channel on a 2.048-Mbps link

The following discussion describes 24-channel interface signaling groups. The 32-channel interface works the same way, except that only port number 16 is used for signaling instead of port number 24. Ports 1 through 15 and 17 through 31 are used for B-Channels. The 32<sup>nd</sup> channel (port 0) is always used for framing.

ISDN-PRI D-channel signaling can be combined with a group of B-Channels in three basic ways:

- 1 FAS (facility-associated signaling)
- 1 NFAS (non-facility-associated signaling)
- 1 Backup NFAS signaling

In a FAS signaling group, the 24<sup>th</sup> port of the TN464 UDS1 Interface circuit pack or DS1 Interface Media Module carries D-channel signaling for up to 23 B-Channel ports on the same circuit pack or media module.

In an NFAS signaling group, the 24<sup>th</sup> port of one TN464C or higher suffix UDS1 Interface or DS1 Interface Media Module can carry D-channel signaling for B-Channels on several other DS1 circuit packs or DS1 Media Modules, as well, including TN767s and TN464Bs. The 24<sup>th</sup> port on the other circuit packs or media modules can be used as a B-Channel. A D-Channel in an NFAS group can signal for B channels on a total of 20 DS1 circuit packs or media modules.

D-channel backup provides increased reliability, which is highly desirable since NFAS permits a D-Channel to signal for many more B-Channels. NFAS allows the administration of a backup D-Channel that remains in a standby state until the active D-Channel goes down. If so, the backup D-Channel takes over and provides signaling for every B channel in the signaling group.

The operation of the entire ISDN-PRI signaling group depends on several other entities:

- 1 The ISDN-PRI signaling channel ports, the TN464 UDS1 Interface circuit pack or DS1 Interface Media Module, on which the D-Channels reside, and the system link that is carried over the packet bus to the processor.

When there are problems with the ISDN-PRI signaling group, also investigate [ISDN-PLK \(ISDN-PRI Signaling Link Port\)](#), [UDS1-BD \(UDS1 Interface Circuit Pack\)](#), [MG-DS1 \(DS1 Interface Media Module\)](#), [SYS-LINK \(System Links\)](#), and [PKT-INT \(Packet Interface\)](#), as appropriate.

## Notes:

- a. **Error Type 0:** Run the short test sequence first. If every test passes, run the long test sequence. Refer to each appropriate test's description, and follow its recommended procedures.
- b. **Error Type 1:** this switch sent a message to the far-end switch or terminal adapter, and the far end did not respond in the allotted time. Possible causes include link failure and congestion or outage at the far end. The Aux Data field contains layer-3 protocol information used by internal counters.
 

If no other symptoms are present, no action is required. If layer-3 communication is down, there should be indications in the screen of alarms and errors for link components. Check for other errors against ISDN-SGR, ISDN-TRK, and other hardware components on the link.

There is no test to clear these errors. An error counter is decremented by 1 every 15 minutes, and the error eventually will be cleared by the system.
- c. **Error Type 257:** the primary signaling channel connection has been lost for more than 90 seconds. If a secondary signaling channel does not exist or is not in service, the associated B-Channels will be placed in the ISDN Maintenance/Far-End state. The B-Channels will not be usable for outgoing calls, although incoming calls will still be accepted. The switch will automatically attempt to recover the signaling link. Check the results of the [Primary Signaling Link Hardware Check \(#636\)](#) in the test sequence. When the link does recover,

the B-Channels will be negotiated back to the In-Service state and their alarms will be retired.

When this error occurs, the state of the Signaling Group is changed to out of service. Verify this with `status signaling-group grp#`.

- d. **Error Type 513:** the secondary signaling channel connection has been lost for more than 90 seconds. If the primary signaling channel is not in service, B-Channels will be placed in the ISDN Maintenance/Far-End state. The B-Channels will not be usable for outgoing calls, although incoming calls will still be accepted. The switch will automatically attempt to recover the signaling link. Note the results of the [Secondary Signaling Link Hardware Check \(#639\)](#). When the link does recover, the B-Channels will be negotiated back to the In-Service state and their alarms will be retired.

When this error occurs, the state of the Signaling Group is changed to out of service (verify using `status signaling-group grp#`).

- e. **Error Type 1793:** The Layer 2 Query Test failed for the primary signaling channel. See [Layer 2 Status Query Test \(#647\)](#)
- f. **Error Type 2049:** The Layer 2 Query Test failed for the secondary signaling channel. See [Layer 2 Status Query Test \(#647\)](#)
- g. **Error Type 2305:** The [Remote Layer 3 Query \(#637\)](#) failed. A specific message was sent to the far-end switch, and it did not respond within the time allowed. Investigate elements of the ISDN PRI D-Channel(s) [ISDN-PLK \(ISDN-PRI Signaling Link Port\)](#) for both this switch and the far-end switch. If Test #637 fails twice in a row, the B-Channels will be alarmed and made unavailable for outgoing calls (although incoming calls will still be accepted). When Test #637 succeeds and the far-end switch starts responding properly, the DS1 ISDN Trunk (B-Channels) will be placed back into normal operation, and their alarms will be retired.
- h. **Error Type 3585:** A SERV or SERV ACK ISDN D-channel message has been received by a non-US-type interface (country option other than 1 on the DS1 Administration screen). However, these messages are used only for NFAS D-channel backup signaling that is supported only by country protocol 1.

Thus, there may be a mismatch in administration between the local and far-end switches. Consult with the customer's network provider to determine whether the D-Channel is set up correctly at the far-end switch.

- i. **Error Types 3842 - 3942:** These Error Types report certain error messages received by the ISDN-PRI Signaling Group for one of its associated B-Channels. The aux data field shows for which B-Channel (port number) the message was received.

The error code generated equals 3840+x, where "x" is a cause value defined by the ISDN-PRI Specification. Note that there is no recommended action for these Error Types; selected ISDN cause values are placed in the log when they are received, but no direct action or alarming is performed solely in response to receiving them. They provide added data that may prove useful when tracking down obscure networking and routing problems. [Table 157](#) provides more information.

Table 157: Descriptions and Recommendations for Error Types 3842-3942 1 of 4

| Error Code    | Description                                                                                                                                                                  | Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|---------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3842          | A request has been made to use a transit network or common carrier that cannot be accessed.                                                                                  | <p>The equipment sending this cause event does not recognize the transit network.</p> <ol style="list-style-type: none"> <li>1. From the circuit pack or media module and port number (in the Aux Data field), determine the trunk group against which the error was reported.</li> <li>2. Check every routing pattern containing this trunk group for validity of interexchange carriers requested (IXC field).</li> </ol>                                                                                                                                                                                                                                                                                                                           |
| 3843          | No route to destination. Request received to route call through a transit network that is recognized but not allowed to carry the call or not able to serve the destination. |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
| 3846          | The far-end switch has indicated that the B-Channel (trunk) is not acceptable for use in the call for which it was requested.                                                | <p>This could indicate an administration problem (for example, the local switch and the far-end switch have different B channels administered), or could reflect the occurrence of a normal race condition (for example, the local switch has requested use of a B-Channel that the far-end switch had just reserved for use on another call).</p> <ol style="list-style-type: none"> <li>1. From the circuit pack or media module and port number (in the Aux Data field), determine the trunk group against which the error was reported.</li> <li>2. Enter <b>status trunk</b> for the indicated trunk. Refer to the "DS1 ISDN Trunk Service States" and "ISDN-PRI Trunk Service States" sections of ISDN-TRK for recovery suggestions.</li> </ol> |
| 3858          | Similar to Error Type 1. The switch sent an ISDN message to the far-end switch or terminal adapter that did not respond in the time allowed.                                 | Follow same recommendations as for Error Type 1.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
| <b>1 of 4</b> |                                                                                                                                                                              |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

**Table 157: Descriptions and Recommendations for Error Types 3842-3942 2 of 4**

| Error Code    | Description                                                                                                                                                                                                              | Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|---------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3878          | The far-end switch has indicated that the network is not functioning correctly and that the condition may last a relatively long period of time (for example, immediately re-attempting the call may not be successful). | <p>Network is out of order.</p> <ol style="list-style-type: none"> <li>1. From the circuit pack or media module and port number (in the Aux Data field, determine the trunk group against which the error was reported.</li> <li>2. Consult with the network provider to determine the nature and expected duration of the out of service condition.</li> <li>3. Consider modifying every routing pattern containing this trunk group to route calls around the network that is out of service.</li> </ol>                                                                                                                                                                                                                                                                                                                                                                                                                                                   |
| 3890          | A request to use a network service (e.g., SDN) has been denied. Administration somewhere on the network has indicated that the requested service has not been subscribed to or purchased for this trunk.                 | <p>This could be a local administration problem only, or a mismatch between the local administration and that of the network provider.</p> <ol style="list-style-type: none"> <li>1. From the circuit pack or media module and port number (in the Aux Data field), determine the trunk group against which the error was reported.</li> <li>2. Display the trunk group form: If the trunk group is Call-by-Call (Service Type is “cbc”), check every routing pattern form containing this trunk group to see if the Service/Feature fields contain the correct network services purchased for this trunk. If the trunk group is not Call-by-Call, check that the Service Type field contains the single network service purchased for this trunk.</li> <li>3. If local administration appears correct, consult with the customer and/or the network provider to determine the services that the customer has subscribed to for this trunk group.</li> </ol> |
| 3892          | Protocol detail; may offer a clue if customer is having ISDN calls denied with an unexpected intercept tone.                                                                                                             | If customer is complaining of unexpected intercept tones when accessing ISDN trunks or PRI endpoints and no other cause can be found, escalate the problem and provide the next tier with this Error Log information.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

Used when no other cause in this class applies.                                                                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| 3928          | A call was denied because of a basic incompatibility existed between the type of call and either the facilities selected by the routing pattern or the called user. | This error might be helpful as a clue if the customer complains of receiving unexpected intercept tone after accessing ISDN trunks or PRI endpoints. Determine the trunk group from the circuit pack or media module and port number (in the Aux Data field) and then check the BCC fields of the pertinent routing patterns. Also, investigate whether or not the calling and called endpoints are compatible (for example, some ISDN switches may not allow a voice station to call a data extension). |
| 3942          | Timer expiry: T310 time-out, no answer to CALL PROCEEDING.                                                                                                          |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |
| <b>4 of 4</b> |                                                                                                                                                                     |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

## Demand test descriptions and error codes

Investigate tests in the order presented. By clearing errors associated with the first test, errors generated from other tests may also be cleared. Click on the link to see the full description of the test, error codes, and recommended actions.

| Order of Investigation                                         | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|----------------------------------------------------------------|---------------------|--------------------|-------------------|
| <a href="#">Primary Signaling Link Hardware Check (#636)</a>   | X                   | X                  | ND                |
| <a href="#">Secondary Signaling Link Hardware Check (#639)</a> | X                   | X                  | ND                |

## ISDN-TRK (DS1 ISDN Trunk)

| MO Name in Log | Alarm Level             | Initial Command to Run               | Full Name of MO |
|----------------|-------------------------|--------------------------------------|-----------------|
| ISDN-TRK       | MAJ <sup>1</sup><br>MIN | <code>test port location long</code> | DS1 ISDN Trunk  |
|                | WRN                     | <code>test port location</code>      |                 |

1. A MAJOR alarm on a trunk indicates that alarms on these trunks are not downgraded by the **set options**.

### Note:

Many trunk problems are caused by incorrect settings of parameters on the trunk group administration screen. Settings must be compatible with the local environment and with parameter settings on the far end. See *Administering Avaya Aura™ Communication Manager*. Refer to your Avaya representative for the correct settings for administrable timers and other parameters on a country-by-country basis.

### Note:

See the figures in the [ISDN-SGR \(ISDN-PRI Signaling Group\)](#) maintenance object for an illustration of the principles described below. Throughout this section, the general term DS1 circuit pack refers to TN464 and TN767 series circuit packs for systems supporting circuit packs and DS1 Interface Media Modules for systems supporting media modules.

For additional repair information, see also [DS1-BD \(DS1 Interface Circuit Pack\)](#) for TN767 ports, [UDS1-BD \(UDS1 Interface Circuit Pack\)](#) for TN464C or higher suffix ports, and [MG-DS1 \(DS1 Interface Media Module\)](#) for Media Module ports.

A DS1 ISDN trunk is a 64-kbps bearer channel used to transmit digitized voice or data traffic. These trunks, or B-Channels, use a separate channel, the D-Channel for call-control signaling. This mode of operation is known as out-of-band signaling, as opposed to in-band robbed-bit signaling, in which signaling is carried in the same channel as the voice or data traffic. One D-Channel, or ISDN signaling link (ISDN-PLK), carries signaling messages for several B-Channels, forming an ISDN signaling group (ISDN-SGR).

A B-Channel may be a port on a TN464 series UDS1 circuit pack, a TN767 series DS1 Interface circuit pack, or an DS1 Interface Media Module.

Two types of DS1 interfaces exist:

- 1 24 DS0 channels on a 1.544-Mbps link
- 1 31 DS0 channels + 1 framing channel on a 2.048-Mbps link

On 24-channel interfaces, any of the first 23 ports on the DS1 circuit packs or media modules can be a B-Channel. On the TN464C or higher suffix UDS1 circuit pack or DS1 Media Module, the 24<sup>th</sup> port may be used as a B-Channel or as a D-Channel depending on the type of ISDN-PRI signaling group (FAS or NFAS) implemented on the circuit pack or media module. For more details, see [ISDN-SGR \(ISDN-PRI Signaling Group\)](#). On the TN767 DS1 circuit pack, all 24 ports are used as B-Channels since D-channel signaling is not supported on the TN767 circuit pack. The signaling for these B-Channels is done over a D-Channel located on a UDS1 TN464C or higher suffix board.

On 32-channel interfaces, any of ports 1 – 15 and 17 – 31 on the DS1 interface circuit pack or media module can be a B-Channel. The 16<sup>th</sup> port may be used as a B-Channel or as a D-Channel depending on the type of ISDN-PRI signaling group (FAS or NFAS) to which it belongs. For more details, see [ISDN-SGR \(ISDN-PRI Signaling Group\)](#) and [DS1-BD \(DS1 Interface Circuit Pack\)](#) or [MG-DS1 \(DS1 Interface Media Module\)](#).

For interfaces using country protocol 1 on the DS1 circuit pack or media module administration form (including US), the signaling protocol used for the maintenance of the B-Channel is defined by the Avaya ISDN-PRI specification. For interfaces using country protocols other than 1, the signaling protocol used for the maintenance of the B-Channel is defined by the CCITT ISDN-PRI Specification.

There are five possible service states for a B-Channel. The service state is negotiated with the far-end switch, changes over time, and may have far-end and near-end components. The service state is initialized to Out-of-Service/Far-End, and an attempt is made to negotiate it to In-Service.

**Note:**

The service state of a particular DS1 ISDN Trunk B-Channel can be displayed by entering `status trunk grp#/mem#` on the system access terminal.

When a call is present, the specification defines the permissible call states, as well. There are tests in the short and long test sequences for DS1 ISDN Trunk designed to audit these states and ensure agreement between both ends of the PRI connection.

---

## Alarming Based on Service States

A warning alarm is logged against a DS1 ISDN B-Channel trunk when it is placed in the Maintenance/Far-End or Out-Of-Service/Far-End states, during which the trunk is unusable for outgoing calls. When a warning alarm is present, use the `status trunk grp#/mem#` command to determine the exact state. Other alarms can be diagnosed by using the short and/or long test sequences.

An ISDN B-Channel trunk can be placed in a Far-End service state by either action taken by the far-end switch or by failure of the far-end switch to respond. For example, if the far end does not respond to a Remote Layer 3 Query test (#637) for ISDN-SGR, the associated DS1 ISDN trunk B-Channels will be placed in the Maintenance/Far-End service state.

As a port on a DS1 circuit pack (DS1-BD or UDS1-BD), or a DS1 Media Module (MG-DS1), and as part of a signaling group dependent on a D-Channel (ISDN-PLK) for signaling, operation of the ISDN-TRK is dependent on the health of these other MOs. In turn, the ISDN D-Channel depends on the packet bus (PKT-BUS) for transmission through the system. Keep this hierarchy of dependencies in mind when diagnosing problems.

---

## DS1 ISDN Trunk Service States

The `status trunk` command shows the following possible service states for ISDN trunks. [Table 158: Service States](#) gives recommended procedures for each state.

1 In-Service (INS)

The B-Channel is in its normal operating state.

1 Out-of-Service/Far-End (OOS/FE)

A B-Channel is initialized to this state when administered. The switch sends messages to the far end to negotiate the B-Channel into service. If the far end does not respond to the messages within a certain time period, then the service state remains out of service and maintenance will periodically resend the messages. The trunk is unusable for incoming and outgoing calls.

On US interfaces, the trunk is unusable for incoming calls, but on non-US interfaces, incoming calls will be accepted.

1 Out-of-Service/Near-End (OOS/NE)

This is the state of the trunk when the NPE Crosstalk Test fails or when the trunk is busied out by the system technician. In this state, the trunk is unusable for incoming or outgoing calls. No messages are sent to the far end until the signaling link comes back into service or the trunk is released by the system technician.

#### 1 Maintenance/Far-End (MTC/FE)

This state is reached when the far end does not respond after a certain amount of time to messages sent over the signaling link for a particular trunk. This state is different from OOS/FE since the signaling link must have initially been up and the B-Channels in service. The switch will periodically send messages to the far end to try to negotiate the trunk (B-Channel) into service. The trunk is unusable for outgoing calls but will service incoming call requests from the far end. Note that transitions into MTC/FE do not drop stable calls. Therefore, if the service state changes from in service to MTC/FE, then stable calls are unaffected.

#### 1 Maintenance/Near-End (MTC/NE)

The trunk (B-Channel) is in this state if the signaling channel (ISDN-PLK) is busied out by the system technician. The trunk (B-Channel) is also temporarily in this state if the system technician enters `test trunk grp#/mem# long`. This command executes the ISDN-PRI test call. This test changes the state of the trunk member to MTC/NE for the duration of the test unless a call request comes in from the far end. In that case, the test would abort. Note that transitions into MTC/NE do not drop stable calls. In this state, the B-Channel is not usable for new incoming or outgoing calls.

#### 1 Pending States

In addition to one of the previous components, the service state may have a *pending* component, indicating that the switch is waiting for a reply from the far end. These service states remain in effect until either a response is received or the allotted waiting time expires.

##### – Pending-in-Service

The near end is awaiting a far-end response to a B-Channel maintenance message requesting that a B-Channel be transitioned to in service.

The far-end has a certain amount of time to respond to the message. The service state will be PINS until either a response is received or the timer expires.

##### – Pending-Maintenance

This state is supported only by systems using country protocol 1 (including US). The near end is awaiting a far-end response to a maintenance message requesting that a B-Channel be transitioned to the maintenance service state. The far-end has a certain amount of time to respond to the message. The service state will be PMTC until either a response is received or the timer expires.

#### 1 Call Activity States

The in-service state also has a call activity component.

##### – Active

A call is connected over the B-Channel (for example, *in service active*).

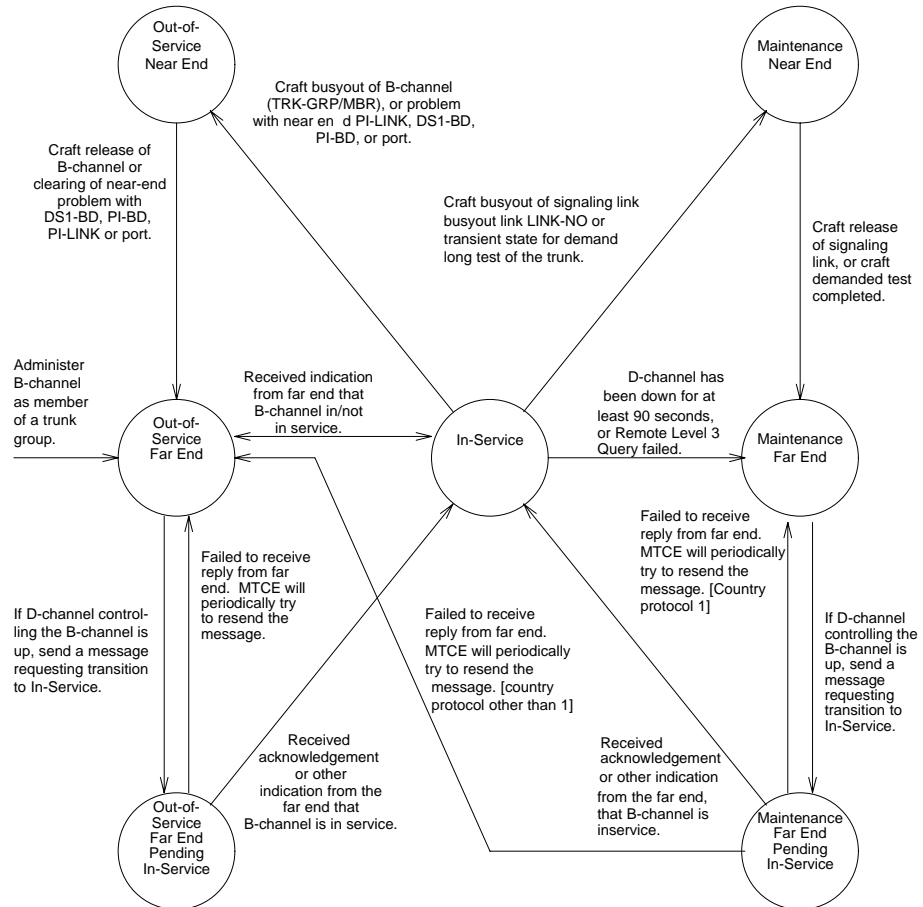

##### – Idle

There is no call currently on the B-Channel (for example, *in service*).

The following diagram of the DS1 ISDN Trunk service states shows the common progression from one service state to another and the event that caused the change of state.

**Figure 35: Common Progressions in Service States**

## ISDN-PRI Trunk Service States

Use `status trunk grp#/mem#` to see DS1 ISDN Trunk service states, as shown in [Table 158: Service States](#).

**Note:**

Refer to [Troubleshooting ISDN-PRI](#) in *Maintenance Procedures (03-300432)* for a layered approach to processing ISDN-PRI problems.

**Table 158: Service States 1 of 2**

| Service State                       | Alarm <sup>1</sup> | Possible Cause                                                                                    | Possible Solution                                                                                                                                                                      |
|-------------------------------------|--------------------|---------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| out-of-service/NE                   | WRN                | Trunk is demand busied out.                                                                       | Enter <code>release trunk grp#/mem#</code> .                                                                                                                                           |
|                                     | MIN                | NPE Crosstalk test (#6) failed.                                                                   | Replace DS1/UDS1 circuit pack.                                                                                                                                                         |
|                                     | None               | DS1 or UDS1 circuit pack or DS1 Media Module lost its signal.                                     | Is the DS1/UDS1 circuit pack, DS1 Media Module, or cable removed? Is the far-end switch restarting? Check circuit pack or media module using procedures in DS1-BD, UDS1-BD, or MG-DS1. |
| out-of-service/FE                   | WRN                | Unadministered far end                                                                            | Administer corresponding trunk on far-end switch.                                                                                                                                      |

| 3585 ( <a href="#">l</a> ) | Any      |                              |                                |              |                                       |
| 3841 ( <a href="#">m</a> ) | Any      |                              | WRN                            | OFF          |                                       |
|                            |          |                              |                                |              | <b>2 of 2</b>                         |

1. Major or minor alarms may be downgraded to Warning alarms based on the value used in the `set options` command.

Notes:

- a. **Error Type 0:** Run the short test sequence first. If every test passes, run the long test sequence. Refer to each appropriate test's description, and follow its recommended procedures.
- b. **Error Type 1:** Disagreement between this switch and the switch at the other end of the trunk connection with regard to the ISDN call state of the DS1 ISDN Trunk. This switch will automatically try to recover by clearing the call, (that is, call will be torn down). You can use `status trunk grp#/mem#` to determine the state of the trunk.  
  
When running the short test sequence, note the results of the [Call State Audit Test \(#257\)](#).
- c. **Error Type 15:** Software audit error and does not indicate a hardware malfunction. Run the short test sequence, and investigate associated errors.
- d. **Error Type 19:** Possible protocol mismatch or far end may be out of service.
- e. **Error Type 129:** The far-end switch changed its ISDN service state to either *out of service* or *maintenance*. This may be either a temporary condition due to far-end testing of that trunk or a hardware problem with the trunk. Outgoing calls will not be allowed over the trunk. To investigate the status of the trunk, enter `status trunk grp#/mem#`.

- f. **Error Type 130:** The circuit pack or media module has been removed or has been insane for more than 11 minutes. To clear the error, reinsert or replace the circuit pack or media module.
- g. **Error Types 257 and 796:** Disagreement between this switch and the switch at the other end of the trunk connection with regard to the ISDN service state of the DS1 ISDN Trunk. This switch will automatically try to recover by performing a service state audit. You can use `status trunk grp#/mem#` to determine the state of the trunk.
- When running the short test sequence, note the results of the [Service State Audit Test \(#256\)](#).
- h. **Error Type 513:** This trunk is not recognized by the far-end switch. Investigate the trunk administration for both switches and make changes as necessary.
- i. **Error Type 1025:** An unexpected SERVICE or SERVICE ACK was received. Possibilities include:
- 1 Translations conflict
  - 1 Protocol differences
  - 1 Survivable Core Server may be using NI3 protocol, not currently implemented in Communication Manager.
  - 1 B-Channel negotiation problem (glare)
- j. **Error Type 1793:** failure of the DS1/UDS1 Interface circuit pack. When running the short test sequence, the results of the [Signaling Link State Audit Test \(#255\)](#) are important.
- k. **Error Type 3073:** [Service State Audit Test \(#256\)](#) failed. The trunks will not be usable for any outgoing calls (although incoming calls will be accepted) until the test passes and the trunk state is changed to in service (use `status trunk grp#/mem#` to investigate trunk status).
- l. **Error Type 3585:** the switch receives an ISDN RESTART message for an ISDN trunk. Calls are cleared with the RESTART message. Therefore, this Error Type may be associated with a dropped call report from a user.

The following Aux Data values for **Error Type 3585** represent the trunk's ISDN call state at the time the unexpected request to restart the channel was received from the remote switch. This information can be useful if dropped calls (cutoffs) are reported by users of the ISDN-PRI trunks.

The meanings of Aux Data values are shown below; ignore any others.

**Table 160: ISDN Trunk - Error 3585 Aux Data Values**

| Aux Data                                 | Cause                                                                                                                                                                                                                                                                                                            |
|------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 0                                        | A idle trunk received a restart.                                                                                                                                                                                                                                                                                 |
| 10                                       | A call in a stable, talking state was cleared unexpectedly by the far end with an ISDN RESTART message. This state is called the "active" state.                                                                                                                                                                 |
| 4,<br>7,<br>8,<br>260,<br>263            | A call that has not reached the active state, but has at least reached a ringing state, was cleared unexpectedly by the far end with an ISDN RESTART message.                                                                                                                                                    |
| 1,<br>3,<br>6,<br>9,<br>265              | A call that has not yet reached a ringing state was cleared unexpectedly by the far end with an ISDN RESTART message.                                                                                                                                                                                            |
| 11,<br>12,<br>19,<br>531,<br>267,<br>268 | A call that was in the process of clearing anyway has been cleared by the far end with an ISDN RESTART message. If this condition occurs frequently, it may mean that the far end is attempting to clear trunks that it thinks are in a "hung" state. The RESTART message brings the trunk to an idle condition. |
|                                          |                                                                                                                                                                                                                                                                                                                  |

- m. **Error Type 3841:** An ISDN trunk selected by the near end has been rejected 10 times by the far end without a successful call. This may indicate a service-state mismatch between the near and far ends for this trunk that is affecting the end user (that is, customer receives unexpected intercept tones when accessing ISDN trunks). This may indicate that the ISDN trunk is not administered at the far end.

The Aux field contains the physical name of the ISDN trunk in decimal. Using this decimal name, verify that the far end has this trunk administered.

The Warning alarm will be retired automatically whenever an outgoing or incoming call that uses this trunk is answered by the called endpoint. If problems persist, then busyout the ISDN trunk to take it out of the hunt group.

---

## Demand test descriptions and error codes

Investigate tests in the order presented. By clearing errors associated with the first test, errors generated from other tests may also be cleared. Click on the link to see the full description of the test, error codes, and recommended actions.

| Order of Investigation                                 | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|--------------------------------------------------------|---------------------|--------------------|-------------------|
| <a href="#">NPE Crosstalk Test (#6)</a>                |                     | X                  | ND                |
| <a href="#">Conference Circuit Test (#7)</a>           |                     | X                  | ND                |

1. D = Destructive, ND = Nondestructive

## JNL-PRNT (Journal Printer Link)

| MO Name in Log | Alarm Level | Initial Command to Run               | Full Name of MO      |
|----------------|-------------|--------------------------------------|----------------------|
| JNL-PRNT       | MIN<br>WRN  | <code>test journal wakeup-log</code> | Journal Printer Link |

The maintenance strategies for JNL-PRNT (Journal Printer Link) and PMS-PRNT (PMS Printer Link) are the same. Refer to [PMS-PRNT \(PMS Printer Link\)](#) for more information.

## LGATE-AJ (Ethernet ASAI Endpoint)

See [BRI-SET, Various Adjuncts](#).

## **LGATE-BD (ISDN-BRI Line Circuit Pack)**

See [BRI-BD \(ISDN-BRI Line Circuit Pack\)](#).

## LGATE-PT (Ethernet Adjunct Port)

See [BRI-PORT \(ISDN-BRI Port\)](#).

## LIC-ERR (License Error Mode)

| MO Name in Log | Alarm Level | Initial Command to Run    | Full Name of MO    |
|----------------|-------------|---------------------------|--------------------|
| LIC-ERR        | MAJ         | <code>test license</code> | License Error Mode |

The LIC-ERR MO works with the NO-LIC MO to look for any errors and violations associated with a License File. Once a License File error occurs, a LIC-ERR error is logged, an alarm is raised, and the following SAT login message is displayed:

*“System Administration Will Be Blocked in Approximately XXX hours.  
Contact Your Service Representative.”*

---

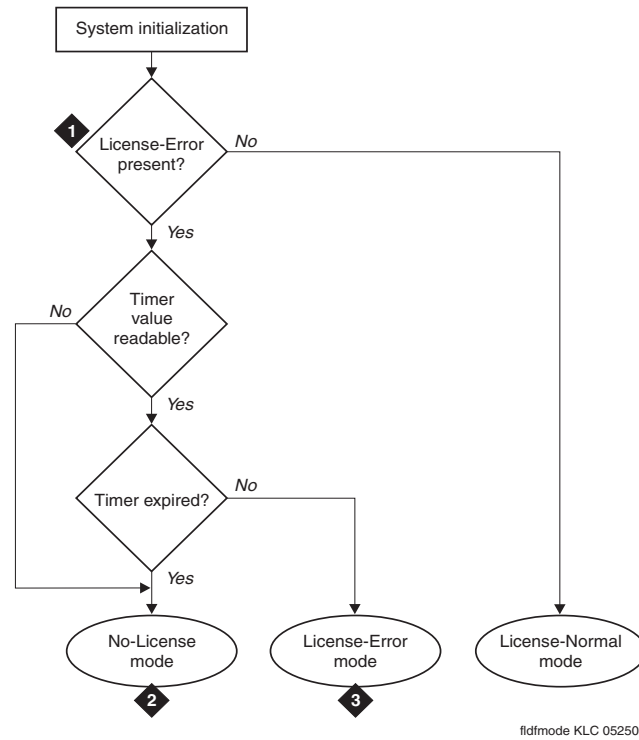

The License File is loaded onto a server during initialization of Communication Manager software, restoration of translations, and periodically during normal operation. After initialization, a query is made to WebLM, a license server plug-in that

- 1 Reads the serial number in a License file.
- 1 Compares this file’s serial number to a serial number in hardware.
- 1 Compares the file’s serial number with a running software version.

If a match occurs, the Web License Generator (WebLM) that resides on a designated server in the enterprise delivers a new feature mask, an information set that controls which features are enabled or not on the Customer Options and Special Applications screens.

Entry into License Error mode starts a timer that, when expired, causes the system to enter No-License mode (see [Figure 36: License mode algorithm](#)).

Figure 36: License mode algorithm

## Figure notes:

1. See [Troubleshooting License File errors](#).
2. See [NO-LIC \(No License\)](#).
3. See [Troubleshooting License File errors](#)

## Error log entries and recommended actions

| Error Type | Aux Data | Associated Test | Alarm Level | On/Off Board | Recommended Action        |
|------------|----------|-----------------|-------------|--------------|---------------------------|

1. These Error Types can be cleared by installing the correct License File.

Notes:

- a. **Error Type 1: S8700 Series S8400| S8500:** The reference IPSI is not responding.  
**S8300:** The motherboard on which the serial number resides is not responding.  
Either the reference is not responding or its serial number does not match the one in the Licence file, and the 30-day timer begins. When the 30-day timer expires, the system enters No-License mode (see [NO-LIC \(No License\)](#), Error Type 1).
- b. **Error Type 513:** The license has expired, and the 30-day timer has started. When the 30-day timer expires, the system enters No-License mode (see [NO-LIC \(No License\)](#), Error Type 513).
- c. **Error Type 769:** Feature use exceeds limits if the license has expired and the 30-day timer begins. When the timer expires, the system enters No-License mode
- d. **Error Type 1537:** The License file is missing or corrupt. A countdown timer for a license error starts only if the previous state was License-Normal.
- e. **Error Type 1793:** The current software version does not match the software version in the License File, and the countdown timer has started. When the timer expires, the system enters No License mode.
- f. **Error Type 2305:** The Offer Category in translation does not match the Offer Category in the License File, and the countdown timer has started. When the timer expires, the system enters No-License mode (see [NO-LIC \(No License\)](#)).

- g. **Error Type 2561:** The license server did not respond in time during the last attempted License File audit.
- h. **Error Type 2817:** Timer response timed out.
- i. **Error Type 3073:** This Survivable Remote Server (the one reporting the LIC-ERR) has gone active because one or more media gateways have registered with it. Follow standard practices to repair the primary server(s) or control network.
- j. **Error Type 3074:** This Survivable Core Server is controlling one or more port networks. Follow standard practices to repair the Main server(s) or control network.
- k. **Error Type 3329:** Platform type/offer type mismatch.
- l. **Error Type 3335:** Platform type does not match hardware.
- m. **Error Type 3391:** Platform type does not match server configuration.
- n. **Error Type 3584:** Invalid Allocation License.
- o. **Error Type 3585:** The Allocation License has an ESID/SID/MID mismatch.
- p. **Error Type 3586:** Allocation License expired.
- q. **Error Type 3841:** Application not found.

## Troubleshooting License File errors

The License file enables the switch's software category, release, features, and capacities. License Files are created using SAP order information and/or current customer configuration information.

Without a valid license installed or with a mismatched license, the system:

1. Generates a major alarm.
2. Starts a 30-day countdown timer (call processing continues)

The License file requires a serial number from either the reference IPSI circuit pack or media gateway motherboard.

The License file includes a license serial identification number that is matched against the hardware in the system as well as information about the Communication Manager software version and Call Center features, Offer Category, and capacities. Once installed or initialized, every hour the system compares these parameters to determine the system status:

- 1 License-Normal mode
  - License file was installed successfully
  - Feature use is within prescribed limits
  - License file's serial number matches the serial number of the reference IPSI
- 1 License-Error mode
  - The License file's serial number reference source is not responding, or its serial number does not match the hardware
  - Communication Manager software versions do not match
  - Feature use exceeded prescribed limits
  - License expired
  - After a system had a valid license, the License file is missing or corrupt.

**Note:**

System resets do not reset the 30-day timer. If a system in License-Error mode is reset and the license error remains, the timer picks up the countdown where it left off.

To clear LIC-ERR alarms, the License file must match the switch hardware and administered parameters.

- 1 No-License mode
  - System software versions do not match.
  - License file is missing or could not be installed.
  - Offer categories do not match.

- A condition that caused the system to enter License-Error mode has not been corrected or resolved, and the countdown timer has expired.
- The switch returns to License-Normal mode when every license error is cleared.

## Login Warning Messages

Anyone logging onto the SAT (System Administration Terminal) when the system is in License-Error or No-License mode, receives a warning message stating the system's Licence mode, depending on the conditions. [Table 162: Error messages and repair procedures](#) shows the 3 license modes, the warning message, describes the error conditions, and lists the recommended repair procedures.

**Table 162: Error messages and repair procedures**

| License Mode   | Description                                                                   | Explanation and repair procedure                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|----------------|-------------------------------------------------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| License-Normal | No mismatches between license and hardware                                    | Stable running condition                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |
| License-Error  | Warning mode; Communication Manager supported, 30-day countdown timer begins. | <p>If you log in to the server through the SAT, a message reads: <i>"System Administration Will Be Blocked in Approximately XXX hours. Contact Your Service Representative."</i> Communication Manager functions normally for 'XXX' hours, at which time the system goes into No-License mode.</p> <p>One of the following conditions is present:</p> <ul style="list-style-type: none"> <li>1 Serial number reference source not responding.</li> <li>1 The License file expired.</li> <li>1 Feature use does not match the License file.</li> </ul> |
| No-License     | Warning period has expired.                                                   | <p>If you log in to the server through the SAT, a message reads: <i>"System Administration Is Blocked. Contact Your Service Representative Immediately."</i></p> <p>One of the following conditions is present:</p> <ul style="list-style-type: none"> <li>1 No License file is installed in the system.</li> <li>1 The License-Error timer expired.</li> </ul>                                                                                                                                                                                       |

## Initialization and Periodic Checking

Within the License file is the feature mask, an information set that controls which features are enabled or not on the Customer Options and Special Applications screens. Each of the approximately 150 feature mask entries is one of three types (examples in parentheses):

- 1 **Type I:** features with a simple on/off state (DCS Call Coverage)
- 1 **Type II:** features with an alphanumeric setting values associated with them (Logged-in ACD Agents)
- 1 **Type III:** includes the product ID (license serial identification number), release number, and capacities.

Type III features cot be changed by any login under any circumstances (applies to IP Telephones, IP Softphones, and IP Agents).

**Table 163: License error messages 1 of 2**

| If the system goes into this mode... | And reports this error message...    | It means that...                                                                                                                                                                                                                                                                                                                                                                                                 |
|--------------------------------------|--------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|

## LOG-SVN (Login Security Violation)

| MO Name in Log | Alarm Level | Initial Command to Run                        | Full Name of MO          |
|----------------|-------------|-----------------------------------------------|--------------------------|
| LOG-SVN        | MAJ         | <code>enable login loginID<sup>1</sup></code> | Login Security Violation |

1. Where *loginID* is the Avaya services login ID for which the security violation was detected. The **Alt Name** field indicates the login ID associated with the security violation and the major alarm.

The Security Violation Notification (SVN) feature provides notification when the number of failed attempts to access the system administration/maintenance interface meets or exceeds customer administered threshold parameters.

A major alarm is logged whenever a security violation is detected involving an Avaya services login ID and that login ID has been disabled as a result of detection of the security violation. The capability to disable a login ID following detection of a security violation involving that login ID is administrable on a per login ID basis.

Refer to the *Administering Avaya Aura™ Communication Manager*, for information about administration required for the Security Violation Notification feature, and the option to disable a login ID following detection of a security violation involving the affected login ID.

---

## Error log entries and recommended actions

**Table 164: LOG-SVN Error Log Entries**

| Error Type | Aux Data | Associated Test | Alarm Level | On/Off Board | Recommended Action                |
|------------|----------|-----------------|-------------|--------------|-----------------------------------|
| 1–15       | None     | None            | Major       | OFF          | <code>enable login loginID</code> |

General Information about log-svn error log entries:

1. The number (1–15), that appears in the Error Type field, corresponds to the location of the login in the internal login data structure.
2. The **Alt Name** field on the alarm report indicates the login ID associated with the security violation and major alarm.
3. These errors/alarms are associated with a number of failed attempts to access the system management/maintenance interface using an Avaya services login ID that meet or exceed the customer administered threshold parameters. The associated alarm is immediately raised as a major alarm.
4. The affected login ID will be disabled as a result of detection of the security violation, unless it is the system's last enabled INADS-type login. The provision to disable a login ID following detection of a security violation involving that login ID is administrable on a login ID basis.

5. Use `enable login` to enable a login that has been disabled, and to retire any login security violation alarms associated with the login ID.
6. To use `enable login` to enable a login and/or retire alarms, use a login ID with greater service level hierarchy permissions.
7. Access to `enable login` is controlled through the **Administer Permissions** field on the **Command Permission Categories** screen. Set the **Administer Permissions** field to **y** to access `enable login`.
8. The **Port** alarm report field identifies the port where the final invalid login attempt, involving the alarmed login ID, was detected.
9. The **Svc State** alarm report field will be set to **OUT** if the login ID is in the disabled state as a result of detection of a security violation involving the login ID. Once the login ID has been enabled, the field will be set to **IN**.
10. The source or reason of the failed login attempts should be identified and the cause corrected prior to re-enabling a login ID and/or retiring any alarms associated with the login ID. The cause may be something as innocuous as the failure of Avaya services automatic login software, to something as insidious as a hacker attempting to gain access to the switch system management interface.

Prior to retiring an SVN alarm and enabling the associated login ID, use `monitor security-violations login` to access information about the invalid login attempts that caused the security violation. This information can be useful in determining the source of the invalid attempts and analyzing why they occurred.

Use `list logins` to see status information about logins on the system. If a login has been disabled as a result of a security violation, the status is **svn-disabled**.

## Procedure to Retire SVN Alarm

To retire a SVN alarm:

1. Enter `enable login loginID`.

The login ID associated with that alarm is displayed in the *Alt Name* field of the alarm report and the alarm is retired.

## MAINT (PN Maintenance Circuit Pack)

S8700-series Fiber-PNC

| MO Name in Log | Alarm Level | Initial Command to Run             | Full Name of MO               |
|----------------|-------------|------------------------------------|-------------------------------|
| MAINT          | MAJ         | <code>test maintenance long</code> | PN's Maintenance circuit pack |
|                | MIN         | <code>test maintenance</code>      |                               |

The TN775D Maintenance circuit pack monitors and supports environmental maintenance for PN multicarrier or single-carrier cabinets. The PN's Maintenance circuit pack provides switch software with a mechanism to activate or deactivate Emergency Transfer in the PN. Control by the system of Emergency Transfer can be overridden by the Emergency Transfer switch on the faceplate of the circuit pack. The PN's Maintenance circuit pack invokes Emergency Transfer when the PN loses contact with the server or when the PN's Maintenance circuit pack loses contact with every Expansion Interface circuit pack. The PN's Maintenance circuit pack handles loss of AC power in the PN multicarrier cabinet by supplying battery power for 15 seconds to the PN cabinet and then an additional 10 minutes of power to just the control carrier in the PN. When power fails in a single-carrier PN cabinet, no such power holdover is available. In the event that an Expansion Interface circuit pack goes insane and is reset six times within 15 minutes, the PN's Maintenance circuit pack will hold the Expansion Links reset preventing the Expansion Interface circuit pack from running.

The PN's Maintenance circuit pack has alarm LEDs which indicate the presence of Major, Minor, and Warning alarms. A flashing LED indicates the presence of an alarm within the cabinet. A continuously lit LED indicates the presence of an alarm elsewhere in the system.

See [CAB-MTCE \(Media Gateway Maintenance\)](#) for an explanation of emergency transfer operation in a G650 Media Gateway port network.

---

## Customer-provided alarming device (CPAD)

The system provides customers a way to connect their own alarm indication device to a switch. The CUST-ALM MO represents this customer-provided alarming device (CPAD).

The customer administers the level of alarm for which the CPAD will be activated using the **change system-parameter maintenance** screen (**CPE Alarm Activation Level** field). The customer sets this field to: **none**, **warning**, **minor**, or **major** depending on the level of alarm at which the CPAD should be activated. When an alarm occurs of at least the level to which the CPAD is administered, the CPAD in the PN will be activated. The CPAD will also be activated within a cabinet whenever Emergency Transfer is invoked within that cabinet.

The CPAD is connected to the PN's Maintenance circuit pack. The CUST-ALM MO is not maintained by the system, and will not generate any alarms. If a problem is suspected with the CPAD, it may be tested using `test customer-alarm`, which will activate the device by closing the relay on either the PN's Maintenance circuit pack (whichever is specified) for 1 minute. The repeat parameter may be used to close the relay for a longer length of time where the number of the repeat is the number of minutes for which the device will be activated (5 minutes is the suggested repeat value).

**Note:**

S8700-series servers and S8500 servers equipped with G650 carriers will differ from this MO, in that the IPSI board provides the CPAD leads. The intent for the feature is in other ways the same.

The `test customer-alarm location` command is provided to allow a technician to check if the customer-provided alarming device is correctly installed and functional. See [Customer-Provided Alarming Device Test \(#115\)](#) for a description of the test. It is recommended that this test be run at least once after both the switch and the customer alarm have been installed.

---

## Connectivity paths

The server communicates with a PN's Maintenance circuit pack via the following path. (Uplink messages back from this Maintenance circuit pack to the server take the reverse path.) Messages flow from the server's processor to an IPSI connected PN's TN2312AP IPSI circuit pack's Packet Interface circuit, over this PN's LAN bus to its Expansion Interface circuit pack, across the fiber link to the active PN's Expansion Interface circuit pack, and over a serial link to the PN's Maintenance circuit pack.

The PN's Maintenance circuit pack must be physically inserted into the dedicated slot marked Maintenance in the A carrier of the PN. The serial links from the PN's Maintenance circuit pack to the Expansion Interface circuit packs are physically connected from this dedicated slot to slots 2A01 and 2B02 (2B02 is used only if there is duplicated Port Network Connectivity). The serial link from slot 2A01 to the maintenance slot is hard-wired into the backplane of carrier A, whereas the serial link from slot 2B02 to the maintenance slot is a ribbon cable connecting the two slots. The serial link from the PN's Maintenance circuit pack to the terminal is also a ribbon cable which plugs into a connector labeled TERM on the back of carrier A.

The maintenance strategy for the PN's Maintenance circuit pack consists of checking the integrity of the communications path to/from the PN's Maintenance circuit pack, testing individual hardware components on the PN's Maintenance circuit pack, and keeping the alarm LEDs up-to-date. The individual hardware components include the serial interfaces which handle the serial links connected to the PN's Maintenance circuit pack. There are three serial interfaces, one for each possible Expansion Interface circuit pack and one for the terminal.

Since the PN's Maintenance circuit pack supports environmental maintenance in the PN, trouble with the PN's Maintenance circuit pack can cause environmental maintenance to falsely detect problems. In a multicarrier cabinet PN, these environmental MOs include: POWER (Battery and Battery Charger), CARR-POW (Carrier Port Power Unit), AC-POWER (AC Power), CABINET (Cabinet Sensors), EMG-XFER (Emergency Transfer), EXT-DEV (External Device Alarm), and CUST-ALM (Customer-Provided Alarming Device). In a single carrier cabinet PN, these environmental MOs include DC-POWER (Single Carrier Cabinet Power), EMG-XFER (Emergency Transfer), EXT-DEV (External Device Alarm), and CUST-ALM (Customer-Provided Alarming Device).

## TN775D Maintenance Circuit Pack Used with a TN2312AP IPSI Circuit Pack

### Connectivity when installed in an Existing System

There is no backplane connectivity from the TN775D Maintenance circuit pack to the TN2312AP IPSI circuit pack in existing pre-R11 carrier backplanes. To achieve connectivity for pre-R11 carriers, a faceplate cable must be used. The faceplate cable runs between the TN775D and the TN2312AP IPSI circuit packs faceplates.

**Note:**

The TN775D maintenance circuit pack is located in slot one of Control Carrier A. The associated TN2312AP IPSI circuit pack is located in slot two of Control Carrier A.

### Backplane Connectivity when Installed in a New System

New systems PN Control Carriers have backplane connectivity between the TN775D Maintenance circuit pack located in slot one of the new PN Control Carrier and the TN2312AP IPSI circuit pack located in slot two. No face plate cable is needed.

---

## Error log entries and recommended actions

**Table 165: MAINT Error Log Entries 1 of 2**

| Error Type | Aux Data | Associated Test                          | Alarm Level | On/Off Board | Recommended Action           |

| 3585 (f)   | Any        | Serial Link Test (#337)                           | MIN<br>WRN <sup>2</sup> | OFF          | test maintenance r 3 |
|            |            |                                                   |                         |              | <b>2 of 2</b>        |

1. Major and Minor alarms may be downgraded to Warning alarms based on the value used in **set options**.

Notes:

- a. **Error Type 0**: run the short test sequence first. If every test passes, run the long test sequence. Refer to each test's description, and follow its procedures.
- b. **Error Type 1, 513, 2561, 2817**: a value of 0 indicates that PNC-A (and therefore, the Expansion Interface circuit pack located on PNC-A) was active when this error occurred. A value of 1 indicates that PNC-B (and therefore, the Expansion Interface circuit pack located on PNC-B) was active when this error occurred. To clear this problem, make sure the active PNC is the same as that indicated by the Aux Value.
- c. **Error Type 769**: multiple values can appear in the *Aux Data* field. There will be other errors in the log if there is a real problem. Use these other errors to troubleshoot the problem.
- d. **Error Type 1537, 2049**: the PN's Maintenance circuit pack hardware vintage does not support battery holdover for all carriers. This failure indicates that the cabinet administration is set for battery holdover for all carriers.

- e. **Error Type 3329, Aux Data 0:** the serial link between the Expansion Interface circuit pack in the A carrier and the PN's Maintenance circuit pack is defective. Aux data of 10 indicates that the serial link between the IPSI circuit pack in the A carrier and the PN's Maintenance circuit pack is defective.
- f. **Error Type 3585, Aux Data 1:** indicates that the serial link between the Expansion Interface circuit pack in the B carrier and the PN's Maintenance circuit pack is defective. Aux data of 11 indicates that the serial link between the IPSI circuit pack in the B carrier and the PN's Maintenance circuit pack is defective.

## Demand test descriptions and error codes

Investigate tests in the order presented. By clearing errors associated with the first test, errors generated from other tests may also be cleared. Click on the link to see the full description of the test, error codes, and recommended actions.

| Order of Investigation                                              | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |

## MAPD-BD (MAPD Interface Circuit Pack)

| MO Name in Log | Alarm Level | Initial Command to Run             | Full Name of MO             |
|----------------|-------------|------------------------------------|-----------------------------|
| MAPD-BD        | MAJ<br>MIN  | <code>test board location 1</code> | MAPD Interface circuit pack |
|                | WRN         | <code>test board location</code>   |                             |

The TN802 Multiple Application Platform (MAP-D) circuit pack allows sending voice and fax from a Communication Manager server through the Internet to another Communication Manager server also having this feature or to other PBXs that are equipped with the Internet Telephony server (ITS-E).

Be sure to observe these special considerations for the TN802:

- 1 Port alarms on this circuit pack display as "TIE-DS1" in the Alarm and Error logs.
- 1 The `reset board` command reboots the MAPD PC CPU, but `busyout board` only busies out every emulated port on the board.
- 1 Switch resets that take the switch out of service for more than 20 seconds also cause the MAPD's PC to reboot, which takes several minutes to complete.

Because of overheating, the TN802 circuit pack should not be placed directly above or below another MAPD circuit pack.

Switch-demanded diagnostic tests on the TN802 do not run unless the Internet trunking application is running on Windows NT, located on the circuit pack.

An uninterruptable power supply (UPS) protection is strongly recommended for a PN containing a TN802 circuit pack.

---

## Backing Up to the PCMCIA Disk

[Table 166: Backing up TN802 administration data](#) details how to back up administration data for the IP trunk application to and restored from the local PCMCIA disk and the Ethernet port. Before backing up, be sure to shut down the application running on the circuit pack, following the procedures in [Shutting Down NT on the TN802](#).

**Table 166: Backing up TN802 administration data**

| Step | Description                         | Comments                                                                                                                                            |
|------|-------------------------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------|
| 1.   | Busyout circuit pack                | On the S8700 Media Server terminal, enter <b>busyout board location</b> (the address of the TN802 circuit pack)                                     |
| 2.   | Backup administration TN802 to disk | At the Windows 2000 desktop, double-click on the <b>IP Trunk Backup Restore</b> icon.<br>The <b>IP Trunk Backup/Restore Utility</b> screen appears. |
| 3.   | Select utility                      | In the IP Trunk Backup/Restore Utility dialog screen, click on <b>Files &gt; Backup</b> .<br>The <b>IP Trunk Backup</b> screen appears.             |
| 4.   | Select backup                       | In the IP Trunk Backup screen, click on the <b>Backup</b> button.                                                                                   |
| 5.   | Wait                                | Backup can take as much as 20 minutes to complete.                                                                                                  |
| 6.   | Release circuit pack                | On the S8700 Media Server terminal, enter <b>release board location</b> (the address of the TN802 circuit pack)                                     |
|      |                                     |                                                                                                                                                     |

**Note:**

Local restore of a complete system from the PCMCIA disk should not require more than 20 minutes assuming that a replacement MAPD pack is available and pre-loaded with the IP trunk application software.

---

## Restoring Data from the PCMCIA Disk

### Before You Start

1. Shut down the application running on the circuit pack. See [Shutting Down NT on the TN802](#).
2. Remove the defective IP Trunk circuit pack from the switch (if applicable).
3. Install the replacement IP Trunk circuit pack in the switch (if applicable).

4. Insert the backup diskette into the IP Trunk circuit pack.

**Table 167: Restore TN802 administration data**

| <b>Step</b> | <b>Description</b>              | <b>Comments</b>                                                                                                                                      |
|-------------|---------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1.          | Restore IP Trunk administration | At the Windows 2000 desktop, double-click on the <b>IP Trunk Backup/ Restore</b> icon.<br>The <b>IP Trunk Backup/Restore Utility</b> screen appears. |
| 2.          | Select utility                  | In the IP Trunk Backup/Restore Utility dialog screen, click <b>Files&gt; Restore</b> .<br>The <b>IP Trunk Backup</b> screen appears.                 |
| 3.          | Select restore                  | In the IP Trunk Backup screen, click on the <b>Restore</b> button.                                                                                   |
| 4.          | Wait                            | Wait until the amber Disk-In-Use LED (Note 5 in <a href="#">Figure 42: TN802 faceplate</a> ) light turns off.                                        |
|             |                                 |                                                                                                                                                      |

---

## Faceplate

[Figure 42: TN802 faceplate](#) shows the TN802 faceplate.

**Figure 37: TN802 faceplate**

**Figure notes:**

- |                                                                                   |                                 |
|-----------------------------------------------------------------------------------|---------------------------------|
| 1. LCD display (see <a href="#">Table 172: TN802 LCD messages for IP trunks</a> ) | 3. Red board-status LED         |
| 2. Reset button (recessed)                                                        | 4. PCMCIA card slot             |
|                                                                                   | 5. Amber PCMCIA disk-in-use LED |

[Table 172: TN802 LCD messages for IP trunks](#) lists the TN802 LCD messages that you might see if installing or servicing an IP Trunk.

**Table 168: TN802 LCD messages for IP trunks 1 of 2**

| Display   | Explanation                                                                                |
|-----------|--------------------------------------------------------------------------------------------|
| PC BOOT   | The TN802 MAPD PC is booting up.                                                           |
| IP TRK #  | IP Trunk application is running (# character blinks).                                      |
| IML DWN # | Internal error on the IP Trunk. System shuts down and sends an error message to the board. |

**1 of 2**

**Table 168: TN802 LCD messages for IP trunks 2 of 2**

| Display                                               | Explanation                                                                                                      |
|-------------------------------------------------------|------------------------------------------------------------------------------------------------------------------|
| MSHUT #,<br>where both<br>MSHUT and<br># are blinking | The system is in the process of shutting down due to a front panel button press. Do not attempt to remove board. |
| MSHUT #,<br>where # is<br>blinking                    | The system has shut down gracefully.                                                                             |

*2 of 2*

## Support for Laptop PCs

Field technicians can access the TN802 circuit pack through:

- 1 pcAnywhere client software
- 1 A directly-connected keyboard, monitor, and mouse

### pcANYWHERE Client Software

1. Attach a male-to-male serial cable and a NULL modem connector (if not built into the cable you use) to the COM2 connector (Note 8 in [Figure 38: TN802 external cable assembly](#)). Attach the other end to the serial port of your laptop.
2. Launch the pcANYWHERE application.
3. Click on Add Remote Control Item.
4. In the Properties window, choose the communication port to which you connected the cable in Step 1.
5. Click on Details and configure the settings ([Table 169: Remote connection settings](#)):

**Table 169: Remote connection settings 1 of 2**

| Field        | Value          |
|--------------|----------------|
| Speed        | 38,400         |
| Parity       | None (default) |
| Flow Control | RTS/CTS        |

*1 of 2*

**Table 169: Remote connection settings 2 of 2**

| Field      | Value                |
|------------|----------------------|
| Started by | Carrier detect (DCD) |
| Ended by   | Carrier detect (DCD) |

**2 of 2**

- Click on the new item icon, and the laptop connects to the host pcANYWHERE application on the TN802 circuit pack.

**Figure 38: TN802 external cable assembly**

**Figure notes:**

- |                               |                            |
|-------------------------------|----------------------------|
| 1. To TN802 cabinet backplane | 5. Mouse                   |
| 2. VGA monitor                | 6. Ethernet                |
| 3. USB (Universal Serial Bus) | 7. 25-pin modem connection |
| 4. Keyboard                   | 8. 25-pin COM2 connection  |

## Directly-Connected Keyboard, Monitor, Mouse

You need 2 power sources for the monitor and the modem in order to complete this procedure.

The TN802 circuit pack must be booted with a local mouse and keyboard connected to it for these devices to work.

- Connect the VGA monitor to the VGA connector of the TN802 external cable.
- Plug the monitor into an AC power receptacle, and turn it on.
- Attach the keyboard to the keyboard connector of the TN802 external cable assembly.

4. Attach the mouse to the mouse connector of the TN802 external cable assembly.
5. Insert the circuit pack to cause it to boot.

---

## Troubleshooting LAN Connections

This section contains information for troubleshooting

- 1 [External Connections to the LAN](#)
- 1 [Internal Connections to the LAN](#)

### External Connections to the LAN

Test the external connections to the LAN by pinging the local host, the external IP trunk server, and another device connected to the network.

1. Click **Start** in Windows (lower left-hand corner), then select **Programs**, then **Command Prompt**.

This starts a DOS command-line session.

2. At the command prompt, enter `ping 127.0.0.1` (the local host's default address).

If configured correctly, the system displays:

**Reply from nnn.nn.nn.nn: bytes=32 time<##ms TTL=###**

If there is no reply, escalate the problem or replace the circuit pack. The problem is not with the external network but within the circuit pack.

3. At the command prompt, enter `ping nnn.nn.nn.nn` (the external IP trunk server's address).

If configured correctly, the system displays:

**Reply from nnn.nn.nn.nn: bytes=32 time<##ms TTL=###**

If there is no reply, verify the IP address and check the physical connections to and from the TN802 circuit pack.

4. At the command prompt, enter `ping nnn.nn.nn.nn` (the IP address of another computer on the network).

If configured correctly, the system displays:

**Reply from nnn.nn.nn.nn: bytes=32 time<##ms TTL=###**

If there is no reply:

- a. Verify the IP address.
- b. Check the physical connections to and from the TN802 circuit pack.

- c. Check the internal cables on the TN802 circuit pack (Notes 4 and 6 in [Figure 40: TN802 board assembly and cables \(side view\)](#)).
  - d. Try pinging another device in the same subnet.
  - e. Try pinging the gateway to the rest of the network from the subnet.
  - f. Try pinging a device outside the local subnet but inside the network or another subnet.
5. When finished, enter **exit** at the command prompt.

## Internal Connections to the LAN

Test the internal connections to the LAN by pinging the local host, an internal IP trunk server, and another device connected to the network.

1. Click **Start** in Windows (lower left-hand corner), then select **Programs**, then **Command Prompt**.

This starts a DOS command-line session.

2. At the command prompt, enter `ping 127.0.0.1` (the local host's default address).

If configured correctly, the system displays:

**Reply from nnn.nn.nn.nn: bytes=32 time <##ms TTL=###**

If there is no reply:

- a. Check that the internal cables on the TN802 circuit pack (Notes 4 and 6 in [Figure 40: TN802 board assembly and cables \(side view\)](#) have not worked loose.
- b. Otherwise, replace the circuit pack.

3. At the command prompt, enter `ping 10.32.64.97` (the internal IP trunk server's address).

If configured correctly, the system displays:

**Reply from nnn.nn.nn.nn: bytes=32 time <##ms TTL=###**

If there is no reply:

- a. Check that the internal cables on the TN802 circuit pack (Notes 4 and 6 in [Figure 40: TN802 board assembly and cables \(side view\)](#)) have not worked loose.
- b. Otherwise, replace the circuit pack.

4. At the command prompt, enter `ping 10.32.64.96` (the IP address of the internal Motorola MPC860 processor).

If configured correctly, the system displays:

**Reply from nnn.nn.nn.nn: bytes=32 time <##ms TTL=###**

If there is no reply:

- a. Check that the internal cables on the TN802 circuit pack (Notes 4 and 6 in [Figure 40: TN802 board assembly and cables \(side view\)](#)) are not loose.

- b. Otherwise, replace the circuit pack.
5. Ping the gateway: at the command prompt, enter `ping xx.xxx.xxx.xxx` (the IP address of the gateway).

When finished, enter `exit` at the command prompt.

---

## Board Assembly and Cables

[Figure 39: TN802 board assembly](#) shows the circuit pack with the two additional boards connected through the side plane.

---

**Figure 39: TN802 board assembly**

**Figure notes:**

- |                                        |                                                             |
|----------------------------------------|-------------------------------------------------------------|
| 1. Main TN802 board                    | 4. Side plane                                               |
| 2. Texas Microsystems Inc. (TMI) board | 5. SCSA (Signal Computing System Architecture) ribbon cable |
| 3. Analogic board                      |                                                             |

---

[Figure 40: TN802 board assembly and cables \(side view\)](#) shows a side view of the three boards and interconnecting cables that make up the TN802.

---

**Figure 40: TN802 board assembly and cables (side view)**

**Figure notes:**

- |                     |                                                             |
|---------------------|-------------------------------------------------------------|
| 1. Main TN802 board | 4. SCSA (Signal Computing System Architecture) ribbon cable |
| 2. Side plane       | 5. Hard drive                                               |
| 3. Analogic board   | 6. Processor I/O ribbon cable                               |

---

[Figure 41: TN802 board assembly and cables \(end view\)](#) shows the end view of the three boards and interconnecting cables on the TN802.

Figure 41: TN802 board assembly and cables (end view)

**Figure notes:**

- |                                                                                                                     |                                                                                                                                                      |
|---------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
| <ul style="list-style-type: none"> <li>1. Analogic board</li> <li>2. TMI (Texas Microsystems Inc.) board</li> </ul> | <ul style="list-style-type: none"> <li>3. SIMMs (memory)<sup>1</sup></li> <li>4. SCSA (Signal Computing System Architecture) ribbon cable</li> </ul> |
|---------------------------------------------------------------------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------|
1. If the board is seated and you hear fast beeping, it means that one of the small boards containing the memory chips is dislodged. Secure the memory board firmly in the receptacle and reseat the circuit pack.

## Replacing the Hard Disk

The TN802 hard drive (Note 5 in [Figure 40: TN802 board assembly and cables \(side view\)](#)) can be replaced in the field.

Table 170: Replacing the TN802 hard drive 1 of 2

| Step | Description              | Comments                                                                                             |
|------|--------------------------|------------------------------------------------------------------------------------------------------|
| 1.   | Shut down Windows 2000.  | Shut down Windows 2000 by either method described in <a href="#">Shutting Down NT on the TN802</a> . |
| 2.   | Remove the circuit pack. | Unlatch the circuit pack, and remove it from the carrier.                                            |
| 3.   | Remove the hard drive.   | Remove the 2 screws, and lift the hard drive out of its mounting bracket.                            |
| 4.   | Replace the hard drive.  | Position the new hard drive in the mounting bracket, and replace the 2 screws (Step 3).              |

**1 of 2**

**Table 170: Replacing the TN802 hard drive 2 of 2**

| Step | Description               | Comments                                                                                                                                                                                                                                                                            |
|------|---------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 5.   | Replace the circuit pack. | Slide the circuit pack into the slot, and lock the latching lever.                                                                                                                                                                                                                  |
| 6.   | Wait for initialization.  | Wait for: <ul style="list-style-type: none"> <li>  the circuit pack to reset (faceplate LEDs light go out).</li> <li>  Windows 2000 boots (PC BOOT appears on the faceplate LCD).</li> <li>  IP Trunk application to run (<b>IP TRK #</b> appears on the faceplate LCD).</li> </ul> |

| 3843 (t)         | 46081    |                                    |                      |              |                                      |
| 3999 (u)         | Any      |                                    |                      |              |                                      |
|                  |          |                                    |                      |              | <b>3 of 3</b>                        |

1. If ports are assigned to the circuit pack, then a minor alarm is raised. If no ports are assigned to the circuit pack, then a warning alarm is raised. The alarm is raised after the circuit pack has been missing for a period of 15 minutes. Warning alarms are also raised against any ports administered on the circuit pack.
2. Minor alarms on this MO may be downgraded to warning alarms based on values set in `set options`.
3. Major alarms on this MO may be downgraded to minor or warning based on values set in `set options`.

Notes:

- a. **Error Type 0:** Run the short test sequence first. If every test passes, run the long test sequence. Refer to each test's description and follow its procedures.
- b. **Error Type 1:** the circuit pack has totally stopped functioning or is not fully administered. The alarm is logged about 15 minutes after the circuit pack has been removed or 11 minutes after the SAKI test (#53) fails.

To be fully administered, a MAPD circuit pack must:

- 1 Have an entry in the circuit plan (`change circuit-pack`)
- 1 Be administered (`add ds1 location`)
- 1 Be physically inserted into the correct slot

If the circuit pack has an entry in the circuit plan and the other two conditions are *not* met, a MINOR alarm is logged. To resolve the error:

- 1 Make sure the circuit pack is properly administered and that a functioning MAPD circuit pack is inserted in the correct slot
- or
- 1 Completely remove the MAPD-BD from the system:
    1. Shut down Windows 2000. See [Shutting Down NT on the TN802](#).
    2. Remove any administered DS1 trunks, access endpoints, or PRI endpoints associated with the circuit pack from their respective trunk groups.

3. Remove the DS1 (**remove ds1 location**) and circuit pack (**change circuit-pack location**) administration.

If the circuit pack is properly administered and the red LED is still on, follow the instructions for LED alarms without Alarm Log entry or with Error Type 1 in *LED Descriptions for Avaya Aura™ Communication Manager Hardware Components (03-602804)*.

- c. **Error Type 2:** Windows 2000 is down and the system attempts to reset the board. If the reset fails, the board may be bad.

1. Replace the circuit pack.

- d. **Error Type 18:** The circuit pack has been busied out.

1. Release the board (**release board location**).

- e. **Error Type 23 and 1025:** The MAPD-BD circuit pack is not completely administered.

To be fully administered, a MAPD circuit pack must:

1. Have an entry in the circuit plan (**change circuit-pack**)
1. Be administered (**add ds1 location**)
1. Be physically inserted into the correct slot

The MAPD circuit pack differs from others in that inserting it into the switch backplane is not enough to make the board usable.

- f. **Error Type 125, no Aux Data:** A wrong circuit pack is inserted in the slot where this circuit pack is logically administered. To resolve this problem:

1. Remove the wrong circuit pack and insert the logically administered circuit pack  
or

1. Re-administer the slot (**change circuit-pack**) to match the circuit pack inserted.

- g. **Error Type 257** see [Control Channel Looparound Test \(#52\)](#) for repair procedures.

- h. **Error Type 513:** Transient hardware problem.

Aux Data 4352 - External RAM failure

Aux Data 4353 - Internal RAM failure

Aux Data 4355 - Internal ROM failure

1. If the same Error Type/Aux Data value occurs more than once in a 24-hour period, the circuit pack should be replaced. See [Shutting Down NT on the TN802](#) before removing the circuit pack.

If the MAPD board detects only one of these hardware problems, then the error is resolved when none of these faults are detected for 10 minutes.

- i. Error Type 514: LAN External RAM Error; hardware fault in the PPE external RAM, used for message buffering to and from the packet bus. This error should not occur regularly.

1. If this error occurs 10 times within 30 minutes, replace the circuit pack. See [Shutting Down NT on the TN802](#) before removing the circuit pack.

- j. **Error Type 769:** Transmit FIFO Underflow (threshold is 3 errors within 10 minutes); the circuit pack cannot find the “end of frame” bit when transmitting a frame to the packet bus.
1. Clear the alarm with:
    - a. *busyout board location*
    - b. *reset board location*
    - c. *test board location long clear*
    - d. *release board location*
  2. If the error recurs within 10 minutes, replace the circuit pack. See [Shutting Down NT on the TN802](#) before removing the circuit pack.
- k. **Error Type 770:** Unable to Write LAN Translation RAM (threshold is 2 errors within 10 minutes); a call is aborted because there are no available translation RAM locations for the call connection attempt.
1. Clear the alarm with:
    - a. *busyout board location*
    - b. *reset board location*
    - c. *test board location long clear*
    - d. *release board location*
  2. If the error recurs within 10 minutes, replace the circuit pack. See [Shutting Down NT on the TN802](#) before removing the circuit pack.
- l. **Error Type 1537:** There was a LAN Bus Timeout because the circuit pack transmitted too many bytes on the LAN bus for a single frame. This condition may be caused by:
1. an on-board fault
  1. faulty data received on one of the circuit pack’s external ports. If any of the ports on this circuit pack are alarmed, refer to the repair procedures for those MOs.

If the error occurs 3 times within 10 minutes, the system raises the board alarm and isolates it from the packet bus.

1. Clear the alarm and restore the board to the packet bus:
  - a. *busyout board location*
  - b. *reset board location*
  - c. *test board location long clear*
  - d. *release board location*
2. If the problem persists, and there are no PKT-BUS alarms or port alarms, replace the circuit pack. See [Shutting Down NT on the TN802](#) before removing the circuit pack.

- m. **Error Type 1538:** Hyperactive circuit pack is out-of-service and may exhibit one or more of the following symptoms:
- 1 The common circuit pack tests (for example, Test #50 and/or Test #52) abort with Error Code 2000.
  - 1 Port tests on this circuit pack return NO-BOARD.
  - 1 A busyout/release of the circuit pack has no effect on test results.
  - 1 A **list configuration** shows that the circuit pack and ports are properly installed.
- The circuit pack is isolated from the system, and every trunk or port on this circuit pack is placed into the out-of-service state. The system attempts to restore the circuit pack within 20 – 30 minutes. When no faults are detected for 20 – 30 minutes, the MAPD Interface circuit pack is restored to normal operation, and every trunk or port on the MAPD Interface circuit pack returns to the in-service state.
- 1. If the board is not restored to normal operation or the error recurs after the board is restored to normal operation, escalate the problem.
- n. **Error Types 3073 – 3160:** Board is reporting slip errors. Aux Data shows the last reported slip count.
- o. **Error Type 3330:** LAN Critical error; critical failure in the packet bus interface to the circuit pack. This failure may be due to an on-board or a packet bus fault.
- 1. If the packet bus is alarmed, see [PKT-BUS \(Packet Bus\)](#) or [PKT-INT \(Packet Interface\)](#) for repair procedures.
- If the packet bus is not alarmed, clear the alarm and restore the board to the packet bus using:
- a. **busyout board location**
  - b. **reset board location**
  - c. **test board location long clear**
  - d. **release board location**
- 2. If the problem persists, and there are no PKT-BUS alarms, replace the circuit pack. See [Shutting Down NT on the TN802](#) before removing the circuit pack.
- p. **Error Types 3585–3601:** The board received misframe errors. Aux Data shows the last reported misframe count.
- q. **Error Type 3840:** The circuit pack received a bad control channel message from the switch. This error is not service-affecting, and requires no action. The value in the **Aux Data** field indicates the cause of the error event.
- r. **Error Type 3841:** The circuit pack detected a transient hardware logic error (for example, program logic inconsistency). This error resolves when no faults are detected for 100 minutes. The value in **Aux Data** field indicates the type of hardware problem.
- s. **Error Type 3842:** Bad Translation RAM Location Found error. The call continues by using another translation location. This error is not service-affecting and requires no action.

- t. **Error Type 3843:** LAN Receive Parity error. The circuit pack detected an error in a received frame from the packet bus. These errors are most likely caused by a packet bus problem, but may be due to a circuit-pack fault.
1. Determine whether the problem is isolated to this circuit pack or the problem is caused by packet bus faults (see [PKT-BUS \(Packet Bus\)](#)).
- u. **Error Type 3999:** The circuit pack sent a large number of control-channel messages to the switch within a short period of time.

| <b>Error Type 1538 (hyperactivity) also present?</b> | <b>Then the system:</b>                                                                                                                                                                        |
|------------------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Y                                                    | Takes the circuit pack out-of-service due to hyperactivity.                                                                                                                                    |
| N                                                    | Does not take the circuit pack out-of-service, but the circuit pack has generated 50% of the messages necessary to be considered hyperactive. This may be normal during heavy traffic periods. |

---

## TN802 Faceplate

[Figure 42: TN802 faceplate](#) shows the TN802 faceplate.

**Figure 42: TN802 faceplate**

**Figure notes:**

- |                                                                                   |                                 |

## Shutting Down NT on the TN802

Before removing the TN802 circuit pack from the carrier, shut down Windows NT on the TN802 by following the procedure described in [Table 173: Windows NT TN802 shutdown procedures](#):

**Table 173: Windows NT TN802 shutdown procedures**

| <b>Step</b> | <b>Faceplate button</b>                                          |
|-------------|------------------------------------------------------------------|
| 1.          | Push the recessed button on the front faceplate and hold it in.  |
| 2.          | “M shut” flashes on the LCD display                              |
| 3.          | When shutdown is complete, “MSHUT #” displays (“#” is blinking). |
| 4.          | Remove the circuit pack.                                         |
|             |                                                                  |

## Demand test descriptions and error codes

Investigate tests in the order presented. By clearing errors associated with the first test, errors generated from other tests may also be cleared. Click on the link to see the full description of the test, error codes, and recommended actions.

| Order of Investigation                                   | Apply to TN802? <sup>1</sup> | Short Test Sequence | Long Test Sequence | Reset Board Sequence | D/ND <sup>2</sup> |
|----------------------------------------------------------|------------------------------|---------------------|--------------------|----------------------|-------------------|
| <a href="#">NPE Audit Test (#50)</a>                     | Y                            |                     | X                  |                      | ND                |

| <a href="#">Major Alarm Inquiry Test (#142)</a>          | N                            | X                   | X                  |                      | ND                |
| <a href="#">Minor Alarm Inquiry Test (#143)</a>          | N                            | X                   | X                  |                      | ND                |
| <a href="#">Slip Alarm Inquiry Test (#144)</a>           | N                            | X                   | X                  |                      | ND                |
| <a href="#">Misframe Alarm Inquiry Test (#145)</a>       | N                            | X                   | X                  |                      | ND                |
| <a href="#">DS1 Translation Update Test (#146)</a>       | N                            | X                   | X                  |                      | ND                |
| <a href="#">SAKI Sanity Test (#53)</a>                   | Y                            |                     |                    | X                    | D                 |

1. N = No; this test either passes or ABORTS with Error Code 2000 (problem with NT)

2. D = Destructive; ND = Nondestructive

## MEDPRO (Media Processor MAPD Circuit Pack)

| MO Name in Log | Alarm Level | Initial Command to Run             | Full Name of MO                   |
|----------------|-------------|------------------------------------|-----------------------------------|
| MEDPRO         | MAJ<br>MIN  | <code>test board location 1</code> | Media Processor MAPD circuit pack |
|                | WRN         | <code>test board location</code>   |                                   |

The TN802B MedPro circuit board provides voice over IP connectivity. The TN802B can run either the:

- 1 IP Trunk application allows the TN802B to emulate a DS1 circuit pack. In this mode, the circuit pack is maintained as a standard DS1 board with its associated Tie trunk ports. The TN802B operates as an integrated Internet Telephony server (ITS). It communicates with other ITS boxes or IP trunk boards.
- 1 Media Processor (MedPro) application allows the TN802B to act as a service circuit to terminate generic RTP streams which carry packetized audio over an IP network. As part of the overall H.323 implementation, the TN802B or later circuit pack handles the audio streams while the TN799DP C-LAN handles the TCP/IP signaling channels. This maintenance plan applies only to a TN802B MedPro running the Media Processor application.

The MedPro hardware combines an Angel complex, a Windows 2000 PC and a TAP802 DSP card in a 3-slot package. When operating as an IP trunk circuit pack, the MedPro emulates a DS1 Tie Trunk circuit pack and blindly responds to DS1 trunk maintenance requests. Actual maintenance is accomplished via the Windows 2000 interface and the ITS software diagnostics.

The Media Processor application is built upon the existing ITS software, and as such is not administered in Communication Manager as a DS1 trunk, and does not emulate a DS1 for maintenance purposes. Use the following Maintenance procedures for this application.

## Error log entries and recommended actions

Table 174: MEDPRO Error Log Entries

| Error Type | Aux Data | Associated Test                                | Alarm Level          | On/Off Board | Recommended Action                     |
|------------|----------|------------------------------------------------|----------------------|--------------|----------------------------------------|
| 0 (a)      | 0        | Any                                            | Any                  | Any          | <i>test board location</i>             |
| 1 (b)      | 0        | Circuit pack removed or SAKI test failed (#53) | MIN WRN <sup>1</sup> | ON           |                                        |
| 18 (c)     | 0        | <i>busyout board location</i>                  | WRN                  | OFF          | <i>release board location</i>          |
| 23 (d)     | 0        |                                                | WRN                  | OFF          | <i>add ip-interface board location</i> |
| 125 (e)    | None     | None                                           | MIN WRN <sup>2</sup> | ON           |                                        |
| 257 (f)    | 65535    | Control Channel Looparound Test (#52)          | MIN                  | ON           | <i>test board location 1 r 2</i>       |
| 1538 (g)   | Any      | Hyperactivity                                  | MIN WRN <sup>2</sup> | ON           |                                        |
| 1793       | Any      | NIC Loss Of Signal                             | MIN WRN <sup>2</sup> |              | <i>test board location 1 r 2</i>       |
| 2049 (h)   | Any      | NT PC Failure                                  | MIN WRN <sup>2</sup> |              | <i>reset board location</i>            |
| 2305       | Any      | IP Address Inconsistency                       |                      |              | <i>test board location 1 r 2</i>       |
| 2561       | Any      | Ping Error                                     | MIN WRN <sup>2</sup> |              | <i>test board location 1 r 5</i>       |
| 3841 (i)   | 4358     |                                                |                      |              |                                        |
| 3999 (j)   | Any      |                                                |                      |              |                                        |

1. If ports are assigned to the circuit pack, then a minor alarm is raised. If no ports are assigned to the circuit pack, then a warning alarm is raised. The alarm is raised after the circuit pack has been missing for a period of 15 minutes. Warning alarms are also raised against any ports administered on the circuit pack.

2. Minor alarms on this MO may be downgraded to warning based on values in `set options`.

Notes:

- a. **Error Type 0:** run the short test sequence first. If every test passes, run the long test sequence. Refer to each test's description, and follow its procedures.
- b. **Error Type 1:** the circuit pack stopped functioning or is not fully administered. The alarm is logged approximately 15 minutes after the circuit pack has been removed or 11-minutes after the SAKI test (#53) fails.

To be fully administered, a MedPro circuit pack must:

- 1 Be physically inserted into the correct slot
- 1 Have an entry in the circuit pack screen (**change circuit-pack**)
- 1 Have the MedPro IP address administered (**change node-names**)
- 1 Be enabled (**change ipserver-interface**)

If the circuit pack has an entry in the circuit pack screen and the other conditions are not met, a MINOR alarm is logged. To resolve the error:

- 1 Make sure every condition for administration is met and that a functioning MedPro circuit pack is inserted in the correct slot.

or

- 1 Completely remove the MedPro from the system using the following steps:
  1. Remove the administered IP-Interface associated with the circuit pack.
  2. Physically remove the circuit pack from the slot.
  3. Execute **remove medpro location** and **change circuit-pack location**.

- c. **Error Type 18:** The MedPro Interface circuit pack has been busied out by **busyout board location**.

1. Release the circuit pack (**release board location**).

- d. **Error Type 23:** The MedPro circuit pack is not completely administered.

To be fully administered, a MedPro circuit pack must:

- 1 Be physically inserted into the correct slot
- 1 Have an entry in the circuit pack screen (**change circuit-pack**)
- 1 Have the MedPro IP address administered (**change node-names**)
- 1 Be enabled (**change ipserver-interface**)

A MEDPRO differs from most circuit packs in that inserting the circuit pack into the switch is not enough to make the board usable. It must also be administered.

- e. **Error Type 125:** No Aux Data: The wrong circuit pack is inserted in the slot where this circuit pack is logically administered.

- 1 Remove the wrong circuit pack and insert the logically administered circuit pack

or

- 1 Re-administer this slot to match the circuit pack inserted (**change circuit-pack**).

- f. **Error Type 257:** See [Control Channel Looparound Test \(#52\)](#) for repair procedures.
- g. **Error Type 1538:** hyperactivity on a circuit pack. Hyperactivity occurs when the Angel is sending too many CCMS messages uplink, 400 per ten seconds for the TN802B, to switch software. The circuit pack will be taken out of service. See error Type 3999.
- h. **Error Type 2049:** the operating system is down. An attempt is made to reset the board automatically. If the reset fails, the board is probably bad and should be replaced.
- i. **Error Type 3841:** Inconsistent downlink message. This error is not service-affecting. No action is required.
- j. **Error Type 3999:** the circuit pack sent a large number of control channel messages to the switch within a short period of time.

If **Error Type 1538** is also present, the circuit pack was taken out-of-service due to hyperactivity.

If **Error Type 1538** is absent, the circuit pack has generated 50% of the messages necessary to be considered hyperactive but was not taken out-of-service. This may be completely normal during heavy traffic periods.

If this Error Type is logged when the circuit pack is being lightly used, it may indicate a problem with the circuit pack or the equipment attached to it.

---

## Demand test descriptions and error codes

Investigate tests in the order presented. By clearing errors associated with the first test, errors generated from other tests may also be cleared. Click on the link to see the full description of the test, error codes, and recommended actions.

| Order of Investigation                                  | Short Test Sequence | Long Test Sequence | Reset Board Sequence | D/ND <sup>1</sup> |

## MEDPRO-C (Media Processor Control)

| MO Name in Log | Alarm Level                                                                                                                             | Initial Command to Run | Full Name of MO         |
|----------------|-----------------------------------------------------------------------------------------------------------------------------------------|------------------------|-------------------------|
| MEDPRO-C       | This MO is not hardware-based. There will be no alarms, commands to run, or tests to clear. Events appear in <b>display event</b> logs. |                        | Media Processor Control |

The TN2602AP IP Media Resource 320 provides high-capacity voice over Internet protocol (VoIP) audio access to the switch for local stations and outside trunks. MEDPRO-C is logged in the Event Log when:

- 1 the TN2602AP becomes active
- 1 the TN2602AP goes into standby
- 1 the TN2602AP peer-link comes up or goes down
- 1 there is a demand interchange between duplicated TN2602AP circuit packs

See [IPMEDPRO \(TN2602AP IP Media Resource 320\)](#) for more information on the TN2602AP.

---

## MEDPRO-C Error Log Entries

The aux data value contains the Angel address of the TN2602AP which caused the event. For information to map the Angel to the carrier/slot location, see [EPN Angel Address/Slot Mapping](#).

**Table 175: MEDPRO-C Error Log Entries 1 of 2**

| Error Type                  | Aux Data | Description                                   |

| 20002                       | Angel    | Craft demand interchange to the active state                                                                                |
| 30000                       | Angel    | Active board failure - no interchange to standby. The board will be taken out of service and calls will be dropped.         |
| 40000                       | Angel    | Peer link to this board is down. Board problem. To isolate the problem, see <a href="#">IPMEDPRO (IP Media Processor)</a> . |
| 40001                       | Angel    | Peer link to this board is up                                                                                               |
| 50000                       | Angel    | The inter-board "hellos" have failed. This is a network issue.                                                              |
| 50001                       | Angel    | The inter-board "hellos" are OK                                                                                             |
| <b>2 of 2</b>               |          |                                                                                                                             |

## Notes:

- a. **Error Type 1:** the circuit pack has been removed from the system or is not fully administered. The error is logged immediately after the circuit pack has been removed or 11 minutes after the SAKI test (#53) fails.

To be fully administered, an IP Media Resource must:

- 1 Have an entry on the circuit pack screen (**change circuit-pack**)
- 1 Have the Media Resource IP address administered (**change node-names**)
- 1 Be enabled (**change ip-interface**)

- 1 Be physically inserted into the correct slot

If the circuit pack has an entry on the circuit pack screen and any of the other conditions are not met, a MINOR alarm is logged. To resolve the error:

- 1 Make sure every condition for administration is met, and that a functioning Media Resource is inserted in the correct slot.
- 1 Completely remove the IP Media Resource from the system:
  - a. Remove the administered IP-Interface associated with the circuit pack.
  - b. Physically remove the circuit pack from the slot.
- b. **Error Type 10012:** Simplex mode downlink. The reason for the state interchange to active was a Simplex mode downlink to the circuit pack. When the board is inserted and before it is used for any bearer traffic, the server configures the board to operate either in Simplex or Duplex mode via a downlink message. That operation may trigger the interchange.
- c. **Error Type 10021 and 10022:** Duplex mode downlink. The reason for the state interchange (active/standby) was a Duplex mode downlink to the circuit pack. When the board is inserted and before it is used for any bearer traffic, the server configures the board to operate either in Simplex or Duplex mode via a downlink message. That operation may trigger the interchange.
- d. **Error Type 10031 and 10032:** Demand interchange. A demand interchange caused the state change (active/standby) in response to the `set media-processor` command.
- e. **Error Type 10041 and 10042:** Free token. The reason for the interchange (active/standby) was that the standby circuit pack detected the availability of a token. Boards operating in duplex mode arbitrate to determine which will be the active board. A hardware-supported soft token supports this operation. The standby circuit pack monitors the token and initiates an interchange if the peer has ceased to be the active board.
- f. **Error Type 10051 and 10052:** Abdicate Request. The state interchange (active/standby) was caused by the board receiving a request to give up the active state. Boards operating in duplex mode exchange health information and other details of duplicated operation. If the standby board determines it must become the active board because it was commanded to do so or because the active board is less healthy than the standby, the standby board sends an abdicate request to the active board.
- g. **Error Type 10061 and 10062:** Abdicate Received. The state interchange (active/standby) was caused by the standby board receiving a notification that the other board was leaving the active state. As part of normal operation, the boards monitor their components and internal state to verify their ability to perform their function. If the board determines it can no longer fulfill the requirements of being the active board, or because it was commanded to do so, it will send an abdicate notification to the standby board.
- h. **Error Type 10110:** The board was configured by CM software to be duplicated but the firmware version of the board does not have this capability. Upgrade the board firmware.
- i. **Error Type 10991 and 10992:** Transient Error. The state interchange (active/standby) was caused by a fault condition that was cleared by the time the state transition was complete.

j. **Error Type 11yy1 and 11yy2:** Health change. The state interchange (active/standby) was caused by a fault condition in the Health parameter indicated by the code (yy). See [Table 176](#) for a description of the Health Parameters monitored by the board and their values.

**Table 176: Health Parameter Index Codes for MEDPRO-C**

| <b>1yy Value</b> | <b>Description</b>                |
|------------------|-----------------------------------|
| 100              | Hardware problem                  |
| 101              | Aggregator communication problem  |
| 102              | No DSPs                           |
| 103              | Firmware resource failure         |

| 105              | Critical Link (Eth or MPCL) fault |
| 119              | Board out of service              |
| 120              | MPCL Relative Fault               |
| 124              | DSP 0                             |
| 125              | DSP 1                             |
| 126              | DSP 2                             |
| 127              | DSP 3                             |
| 128              | Software State of Health          |
| 129              | DoS Attack                        |
| 130              | IP Conflict                       |
| 131              | Network Configuration             |

## MEDPROPT (MEDPRO DSP PORT)

| MO Name in Log | Alarm Level | Initial Command to Run          | Full Name of MO                        |
|----------------|-------------|---------------------------------|----------------------------------------|
| MEDPROPT       | MIN<br>WRN  | <code>test port location</code> | TN802/TN2302/TN2602<br>MEDPRO DSP PORT |

The Media Processor Port (MEDPROPT) MO monitors the health of the Media Processor (MEDPRO) digital signal processors (DSPs). This maintenance object resides on the TN802/TN2302/TN2602 Media Processor circuit packs.

The TN802B MAP-D (Multi-Application Platform for DEFINITY) Media Processor circuit pack, the TN2302, and TN2602 Media Processor circuit packs provide the audio bearer channels for H.323 voice over IP calls.

- 1 One TN802B circuit pack has one MEDPROPT media processing resource; that one TN802B MEDPROPT can handle 31 channels, for a total of 31 channels per TN802B. Note that the TN802B has 11 physical DSP devices but they are treated as one logical MEDPROPT by Communication Manager software. If the `list ip-codec-set` screen specifies only G.711 mu-law or G.711 a-law as the audio codecs, the TN802B MEDPROPT can service 31 channels. If any other codec type (G.723-5.3K, G.723-6.3K, or G.729) is administered, the TN802B MEDPROPT can service 22 channels.
- 1 One TN2302AP has 8 MEDPROPTs. Each TN2302 MEDPROPT has the processing capacity to handle 8 G.711 coded channels, for a total of 64 channels per TN2302. Note that early TN2302AP boards have eight physical DSP devices. Vintage 11 and later TN2302AP boards have two physical DSP devices. Both board configurations provide eight MEDPROPTs and a total of 64 channels.

When only G.711 codecs are in use the TN2302AP has the processing capacity to handle 64 channels. If only G.723/G.729 codecs are in use the TN2302AP has the processing capacity to support 32 channels. If a combination of G.711 and G.723/G.729 codecs are in use the number of channels supported will fall somewhere between 32 and 64. Use the `list ip-codec-set` command to display the administered codecs.

- 1 The capacity provided by the TN2602 is controlled by the Communication Manager license file and may be set at either 80 G.711 channels or 320 G.711 channels. Depending on the codecs used by individual calls the number of simultaneous calls supported will vary. The TN2602 supports G.711, G.729A, G.729AB, and G.726 codecs.

If individual DSPs on the TN802B or TN2302AP or TN2602 fail, the board remains in-service at lower capacity.

The MEDPROPT is a shared service circuit. It is shared between H.323 trunk channels and H.323 stations. An idle channel is allocated to an H.323 trunk/station on a call-by-call basis.

## Error log entries and recommended actions

Table 177: MEDPROPT Error Log Entries

| Error Type | Aux Data | Associated Test                 | Alarm Level | On/Off Board | Recommended Action               |
|------------|----------|---------------------------------|-------------|--------------|----------------------------------|
| 0 (a)      | 0        | Any                             | Any         | Any          | <i>test board location</i>       |
| 1 (b)      | Any      | DSP Capacity test (#1382)       |             | ON           | <i>test board location 1 r 5</i> |
| 18 (c)     | 0        | <i>busyout port location</i>    | WRN         | OFF          | <i>release port location</i>     |
| 258 (d)    | Any      | DSP Capacity test (#1382)       | WRN         | ON           | <i>test board location 1 r 5</i> |
| 513 (e)    |          | DSP Capacity test (#1382)       | MIN         | ON           | <i>test port location</i>        |
| 515 (f)    | Any      | DSP Capacity Query test (#1382) | MIN         | ON           | <i>test board location 1 r 5</i> |
| 769        | Any      | TDM NIC Looparound test (#1380) | MIN         | ON           | <i>test port location 1 r 10</i> |
| 770 (g)    |          |                                 |             |              |                                  |
| 1025 (h)   | Any      |                                 |             |              |                                  |

Notes:

- a. **Error Type 0:** Run the short test sequence first. If every test passes, run the long test sequence. Refer to each test's description and follow its procedures.
- b. **Error Type 1:** For the TN802B only, less than three DSPs are OOS (out of service), and no alarm is raised. The **Aux Data** field contains the number of DSPs that are OOS.
- c. **Error Type 18:** the MEDPRO has been busied out by *busyout port location*.
  1. Release the port (*release port location*).
- d. **Error Type 258:** For the TN802B only, more than three, but less than 9 DSPs are OOS (out of service), and a WARNING alarm is raised. The **Aux Data** field contains the number of DSPs that are OOS.
- e. **Error Type 513:** For the TN2302 and TN2602 only, the port is OOS (out of service) because an associated DSP is bad.

- f. **Error Type 515:** For the TN802B only, this Error Type indicates that every DSP is OOS (out of service), and a MINOR alarm is raised. The **Aux Data** field contains the number of DSPs that are OOS.
- g. **Error Type 770:** DSP overallocation error. Since this error causes the DSP audit to run, the condition is cleared and no action is necessary. This error is logged only. No alarms are generated.
- h. **Error Type 1025:** The port is OOS (out of service) because of a board-level failure. Check for errors/alarms against the board, in particular ping problems, IP address inconsistency, or board sanity problems.
  1. Verify correct administration.
  2. Check cabling and customer network before replacing circuit pack.

---

## Demand test descriptions and error codes

Investigate tests in the order presented. By clearing errors associated with the first test, errors generated from other tests may also be cleared. Click on the link to see the full description of the test, error codes, and recommended actions.

| Order of Investigation                               | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|------------------------------------------------------|---------------------|--------------------|-------------------|
| <a href="#">DSP Query Test (#1382)</a>               | X                   | X                  | ND                |
| <a href="#">DSP Port TDM Looparound Test (#1380)</a> | X                   | X                  | ND                |
| <a href="#">DSP Port Status Query Test (#1407)</a>   | X                   | X                  | ND                |

1. D = Destructive; ND = Nondestructive

## MED-GTWY (MEDIA GATEWAY)

| MO Name in Log | Alarm Level       | Initial Command to Run                   | Full Name of MO |
|----------------|-------------------|------------------------------------------|-----------------|
| MED-GTWY       | MAJ<br>MIN<br>WRN | <code>test media-gateway location</code> | Media Gateway   |

The MED-GTWY maintenance object monitors the H.248 link to the Media Gateway. It logs errors when there are H.248 link problems or when hyperactive H.248 link bounce occurs.

## Error log entries and recommended actions

Table 178: MED-GTWY Error Log Entries

| Error Type                 | Aux Data | Associated Test                         | Alarm Level | On/Off Board | Recommended Action |
|----------------------------|----------|-----------------------------------------|-------------|--------------|--------------------|
| 1 ( <a href="#">a</a> )    |          |                                         | MAJ         | OFF          |                    |
| 257 ( <a href="#">b</a> )  |          |                                         | MAJ         | OFF          |                    |
| 513 ( <a href="#">c</a> )  |          |                                         | MAJ         | ON           |                    |
| 769 ( <a href="#">d</a> )  |          |                                         | MIN         | OFF          |                    |
| 1025 ( <a href="#">e</a> ) |          |                                         | WRN         | OFF          |                    |
| 1281 ( <a href="#">f</a> ) |          | Media Gateway Hyperactive Audit (#1659) | MIN         | OFF          |                    |

### Notes:

- a. **Error Type 1:** failure of the H.248 link keep alive messages between the server and the Media Gateway. This is an indication that the LAN or the platform is down.
- b. **Error Type 257:** If the server is a Survivable Remote Server, at least one Media Gateway is registered with the Survivable Remote Server.
- c. **Error Type 513:** there is a problem on the Media Gateway. Log on to the Media Gateway and check the error log for problems using the MGP CLI.
- d. **Error Type 769** is a transient error, indicating that the link has unregistered with the Media Gateway. If the Media Gateway re-registers, the alarm is resolved. If the Link Loss Delay Timer (LLDT) on the primary server expires, Error Type 1 is logged.

- e. **Error Type 1025:** Due to high traffic, the media gateway socket control process turned off board and port periodic maintenance. When traffic levels decline, periodic maintenance will be turned on again and the alarm resolved.
- f. **Error Type 1281:** This error indicates that there has been a repetitive sequence of unregistration and subsequent re-registration of a media gateway from a call server. The call server may be a primary server, a Survivable Remote Server, or a Survivable Core Server. This error and alarm can only be generated if **Enable Detection and Alarms for Hyperactive Media Gateway Registration** has been enabled on the **system-parameters ip-options** form. This alarm is most likely caused by an IP network problem which causes the gateway to unregister and re-register multiple times to a server within an interval that is less than the link bounce time. If a Survivable Remote Server is present, and if the interval is greater than the link bounce time, the media gateway and affected IP phones would most likely fail over to the Survivable Remote Server, and this MED-GTWY alarm would not be generated. The **disable/enable nr-registration network-region** commands can be used to deny registration of media gateways and IP phones from a server in order to cause the media gateways and IP phones to search for an alternate server. The alarm is resolved if there is no activity for 15 minutes. See [NR-REG \(Network Region Registrations\)](#).

---

## Demand test descriptions and error codes

| Order of Investigation                                         | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|----------------------------------------------------------------|---------------------|--------------------|-------------------|

1. D = Destructive; ND = Nondestructive

## MET-BD (MET Line Circuit Pack)

| MO Name in Log | Alarm Level | Initial Command to Run     | Full Name of MO       |
|----------------|-------------|----------------------------|-----------------------|
| MET-BD         | MIN<br>WRN  | <i>test board location</i> | MET Line circuit pack |

See [XXX-BD \(Common Port Circuit Pack/Media Module\)](#) for Multibutton Electronic Telephone circuit pack errors.

See [MET-LINE \(MET Line\)](#) for related line information.

## MET-LINE (MET Line)

| MO Name in Log | Alarm Level | Initial Command to Run            | Full Name of MO |
|----------------|-------------|-----------------------------------|-----------------|
| MET-LINE       | MIN         | <code>test port location 1</code> | MET Line        |
|                | WRN         | <code>test port location</code>   |                 |

The TN735 MET Line circuit pack supports four Multibutton Electronic Telephone (MET) station sets. Each MET set uses three pairs of wires: an analog voice pair, a transmit pair, and a receive pair. Power is sent over the transmit and receive pairs. The MET Line circuit pack supports every 10-, 20-, and 30-button set.

This section describes MET-LINE (MET Line) maintenance. MET-LINE maintenance is closely related to, and interacts with, MET-BD (MET Line circuit pack) maintenance. This interaction should be kept in mind when troubleshooting MET Line problems.

This section occasionally refers to a station's *service states*. The service states are defined as follows:

|                   |                                                                                                                                                                                                                                                                                                                                       |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Out-of-Service    | The port, and thus the station, have been removed from service. A busyout of a port will cause it to be out-of-service.                                                                                                                                                                                                               |
| Ready-for-Service | The port on the circuit pack has been put into service, but the voice terminal has not yet established signaling communications with the port.                                                                                                                                                                                        |
| In-Service        | The voice terminal has established signaling communications with the port, and the system is ready to process calls to and from that station. A terminal in the ready-for-service state will progress to the in-service state if it is functioning normally, but it can also be forced into the in-service state if it goes off-hook. |

Use `status station` to determine terminal service state. Status is reported as out-of-service, in-service, or disconnect, which means the station is in the ready-for-service state.

---

## Error log entries and recommended actions

**Table 179: MET-LINE Error Log Entries 1 of 2**

| Error Type | Aux Data | Associated Test | Alarm Level | On/Off Board | Recommended Action              |
|------------|----------|-----------------|-------------|--------------|---------------------------------|
| 0 (a)      | 0        | Any             | Any         | Any          | <code>test port location</code> |
|            |          |                 |             |              | <i>1 of 2</i>                   |

| 1793       |          | NPE Crosstalk Test (#6)         | MIN<br>WRN <sup>1</sup> | ON           | <i>test port location 1 r 3</i> |
| 2049 (h)   | 32770    |                                 |                         |              |                                 |
| 2049 (h)   | 40967    |                                 |                         |              |                                 |
| 3840 (i)   | 40989    |                                 |                         |              |                                 |
|            |          |                                 |                         |              | <b>2 of 2</b>                   |

1. Major or Minor alarms MO can be downgraded to Warning based on the values in `set options`.

## Notes:

- a. **Error Type 0:** run the short test sequence first. If every test passes, run the long test sequence. Refer to each test's description and follow its procedures.
- b. **Error Type 1:** the data link between the port and the terminal is not operational (that is, the port circuitry has detected an off-board problem). Verify that the MET set is connected and that the EPF (Electronic Power Feed) test passes. If data transmission problems are experienced, check for defective wiring or a defective voice terminal, or move terminal electrically closer to the switch (that is, reduce the length of the wiring between the terminal and the switch). If the problem persists, replace the circuit pack. Once the problem is resolved, the system retires the alarm after a predetermined time delay.
- c. **Error Type 18:** is logged when maintenance personnel busyout the port. The port is released from busyout using `release port location`.

- d. **Error Type 130:** the circuit pack has been removed or has been insane for more than 11 minutes. To clear the error, reinsert or replace the circuit pack.
- e. **Error Type 257:** the EPF has been turned off due to an overcurrent condition at the voice terminal. Check for defective wiring or a damaged jack, and verify that the voice terminal is an MET set. Once the problem is resolved, the system retires the alarm after a predetermined time delay.
- f. **Error Type 513:** the EPF inquiry audit has returned “epf-no-load” messages. This usually indicates that the voice terminal has been disconnected or that there is a defect in the wiring to the terminal. Check out both possibilities.  
  
When the EPF inquiry audit subsequently receives an “epf-on-ok” or an “epf-off-ok” message, the system will take action to retire the alarm.
- g. **Error Type 1537:** the port has reported a problem with the data link to the voice terminal. Ignore this error if there are no complaints about the voice terminal. Otherwise, make sure the voice terminal is connected, check for defective wiring, check for a defective voice terminal, and decrease the length of the wiring between the voice terminal and the switch. If the problem persists, replace the circuit pack.
- h. **Error Type 2049, Aux Data 32770:** the voice terminal went off-hook while it was in the ready-for-service state. Use **status station** to determine the state of the voice terminal. The off-hook should have moved the station to in-service. No repair action is necessary.  
  
**Error Type 2049, Aux Data 40967:** this code is generated when the link between the circuit pack and the voice terminal is successfully reset. No repair action is necessary.
- i. **Error Type 3840:** the hardware sent an uplink message indicating that the Electric Power Feed (EPF) is not loaded, that is, it is not currently supplying power to a voice terminal. No repair action is necessary.

---

## Demand test descriptions and error codes

Investigate tests in the order presented. By clearing errors associated with the first test, errors generated from other tests may also be cleared. Click on the link to see the full description of the test, error codes, and recommended actions.

| Order of Investigation                                           | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |

1. D = Destructive, ND = Nondestructive

## MG-ANA (Analog Media Module)

| MO Name in Log | Alarm Level | Initial Command to Run                | Full Name of MO     |
|----------------|-------------|---------------------------------------|---------------------|
| MG-ANA         | MIN         | <code>test board location long</code> | Analog Media Module |
|                | WRN         | <code>test board location</code>      |                     |

The MG-ANA maintenance strategy supports the following:

- 1 MM711 (8 port analog line media module)
- 1 MM714 (4 analog line ports + 4 analog trunk ports media module)
- 1 MM716 (24 port analog media module)
- 1 TIM508 (8 analog line ports for Juniper Media Gateways)
- 1 TIM514 (4 analog trunk ports + 4 analog line ports for Juniper Media Gateways)
- 1 TIM516 (16 analog line ports for Juniper Media Gateways)
- 1 TIM518 (8 analog line ports and 8 analog trunk ports for Juniper Media Gateways)
- 1 VMM\_ANA (1 analog trunk port + 2 analog line virtual ports)
- 1 VMM\_42ANA (4 analog trunk ports + 2 analog line virtual ports)

**Note:**

Too many MM711 Analog Media Modules in a G700 might trip the G700 electronic breaker and cause the power supply for the entire G700 to shut down.

---

## Error log entries and recommended actions

**Table 180: MG-ANA Error Log Entries 1 of 2**

| Error Type | Aux Data | Associated Test                            | Alarm Level | On/Off Board | Recommended Action                  |
|------------|----------|--------------------------------------------|-------------|--------------|-------------------------------------|
| 0 (a)      | 0        | Any                                        | Any         | Any          | <code>test board location</code>    |
| 1 (b)      | 0        | Board removed or SAKI Sanity Failure (#53) | MIN         | ON           |                                     |
| 18 (c)     | 0        | <code>busyout board location</code>        | WRN         | OFF          | <code>release board location</code> |
| 23 (d)     | 0        |                                            | WRN         | OFF          |                                     |
| 125 (e)    |          |                                            | MIN         | ON           |                                     |

| 3840 (l)   | Any      | Inconsistent Downlink Message         |             |              |                                 |
|            |          |                                       |             |              | <b>2 of 2</b>                   |

## Notes:

- a. **Error Type 0:** Run the short test sequence first. If every test passes, run the long test sequence. Refer to each appropriate test's description, and follow its recommended procedures.
- b. **Error Type 1:** The media module stopped functioning or has been physically removed from the system. The alarm is logged approximately 11 minutes after removal of the board or failure of the SAKI Sanity Test (#53). Check for the physical presence of the media module in the slot indicated by the alarm. If the board is absent, insert one of the proper type. If the media module is present and its red LED is lit, see LED alarms without Alarm Log entry or with Error Type 1 in *LED Descriptions for Avaya Aura™ Communication Manager Hardware Components (03-602804)*
- c. **Error Type 18:** The media module has been busied out. Release the media module using *release board location*.
- d. **Error Type 23:** The media module has been logically administered but not physically installed. The alarm should clear when the media module is installed.  
 If the media module is already installed:
  1. Run *test board location long* and look at any test failures or Error Codes generated.
  2. If the test does not clear error 23, then execute *reset board location* and run the long test again.
  3. If the reset/test does not clear error 23, replace the media module.
- e. **Error Type 125:** the media module that is physically installed in the slot does not match the type that is administered for that slot. Do one of the following:
  1. Remove the incorrect media module and replace it with one of the type that is administered for that slot.

- l. Use `change media-module` to re-administer the slot so that it matches the board that is installed, then enter `reset board location`.
- f. **Error Type 257:** transient communication problems between the switch and this media module. Execute `test board location` and refer to the repair procedures for the [Control Channel Looparound Test \(#52\)](#).
- g. **Error Type 513:** there is an on-board hardware failure. The system will continuously test the media module and report the results approximately every 10 minutes. If the hardware problem is resolved, the alarm will clear in approximately 30 minutes. If the alarm does NOT clear in 30 minutes, then the media module should be replaced.
- h. **Error Type 769:** This error can be ignored, but look for other errors on this media module.
- i. **Error Type 1025:** This error is not service-affecting and no action is required.
- j. **Error Type 1281:** This error is not service-affecting and no action is required.
- k. **Error Type 1538:** The hyperactive media module is out-of-service and may exhibit one or more of the following symptoms:
  - 1. The tests such as Test #51 and/or Test #220 are aborting with Error Code 2000.
  - 2. The tests run on the ports of this media module are returning NO-BOARD.
  - 3. A busyout/release of the media module has no effect on test results.
  - 4. A `list configuration` command shows that the media module and ports are properly installed.
 If this error happens again within 15 minutes, replace the media module.
- l. **Error Type 3840:** This error is not service-affecting and no action is required.

---

## Demand test descriptions and error codes

Investigate tests in the order presented. By clearing errors associated with the first test, errors generated from other tests may also be cleared. Click on the link to see the full description of the test, error codes, and recommended actions.

| Order of Investigation                                | Short Test Sequence | Long Test Sequence | Reset Board Sequence | D/ND <sup>1</sup> |
|-------------------------------------------------------|---------------------|--------------------|----------------------|-------------------|
| <a href="#">Ringing Application Test (#51)</a>        | X                   | X                  |                      |                   |
| <a href="#">Control Channel Looparound Test (#52)</a> | X                   | X                  |                      | ND                |

## MG\_ANN (Media Gateway Announcement Module)

| MO Name in Log | Alarm Level | Initial Command to Run | Full Name of MO            |
|----------------|-------------|------------------------|----------------------------|
| MG-ANN         | MIN         | test board             | Media Gateway Announcement |
| MG-ANN         | WRN         | test board             | Media Gateway Announcement |

### Error log entries

Table 181: MG-ANN Error Log Entries

| Error Type | Aux Data | Associated Test | Alarm Level | On/Off Board | Test to Clear Value |
|------------|----------|-----------------|-------------|--------------|---------------------|
| 18         | 0        | Busyout board   | WRN         | ON           | release board       |
| 257        | Any      | Test # 52       | MIN         | ON           | test board          |
| 2561 (a)   | Any      | Test # 1683     | MIN         | OFF          | test board          |
| 2562 (b)   | Any      | Test # 1683     | MIN         | OFF          | test board          |
| 2564 (c)   | Any      | Test # 1683     | MIN         | OFF          | test board          |
| 2563       | Any      | Test # 1683     | MIN         | OFF          | test board          |
| 2565       | Any      | Test # 1683     | MIN         | OFF          | test board          |
| 2566       | Any      | Test # 1683     | MIN         | OFF          | test board          |
| 2567 (d)   | Any      | Test # 1683     | MIN         | OFF          | test board          |
| 2592 (e)   | Any      |                 | MIN         | OFF          |                     |

Notes:

- a. **Error Type 18:** the media module has been busied out. Release the media module using release board location.
- b. **Error Type 257:** transient communication problems between the switch and this circuit pack or media module. Execute test board location and refer to the repair procedures for the Control Channel Looparound Test (#52).
- c. **Error Type 2561:** during the last attempted License File audit, the license server did not respond in time.
- d. **Error Type 2562:** retry Failure error. This error is only logged. It is not a hardware failure and hence does not start any testing or generate any alarms. This error comes from call processing and is generated when a second attempt (retry) to seize an outgoing trunk fails.

- e. **Error Type 2563:** The 2563 is a combination of 2561 and 2562.
- f. **Error Type 2565:** The 2565 is a combination of 2564 and 2561.
- g. **Error Type 2566:** The 2566 is a combination of 2562 and 2564.
- h. **Error Type 2567:** The 2567 is a combination of all the preceding errors. This error indicates that the Media Gateway registered and an "enable file systems" message was sent to the gateway to enable the file system with Compact Flash. The Media Gateway refused the message because there is insufficient RAM to support the Compact Flash.

## MG-ANN (Voice Announcements)

The MG-ANN (Voice Announcements) maintenance object provides per board announcement storage time of up to 20 minutes (15 playback ports and 1 recording port that can also be used as a playback port), and allows for announcement file portability via LAN connectivity. MG-ANN also allows for LAN backup and restore of announcement files and the use of customer provided waveform (.WAV) files.

**Note:**

The S8300 does not support standard port networks and TN type boards.

Communication Manager supports the MG-ANN by using a virtual board concept to allow for board insertion and maintenance testing. The virtual slot location is V9.

Announcement times and ports vary according to the media gateway type.

**Table 182: Media Gateway Announcement Times/Ports**

| Media Gateway | Ports     | Minutes |
|---------------|-----------|---------|
| G700          | 15/1 = 16 | 20      |
| G350          | 7         | 20      |
| G250          | 7         | 10      |
| G430          | 7         | 15      |
| G450          | 63/1 = 64 | 45/240  |
| J4350         | 16        | 10      |
| J6350         | 16        | 10      |

---

## Demand test descriptions and error codes

There are no demand tests for MG-ANN.

## MG-BRI (BRI Trunk Media Module)

| MO Name in Log | Alarm Level | Initial Command to Run           | Full Name of MO        |
|----------------|-------------|----------------------------------|------------------------|
| MG-BRI         | MIN         | <code>test board location</code> | BRI Trunk Media Module |

The following is a list of supported BRI Media Modules:

- 1 MM720 (8-port 4-wire BRI Trunk/Line Media Module)
- 1 MM722 (2-port 4-wire BRI Trunk Media Module)
- 1 TIM521 (4-port BRI Trunk Media Module in a Juniper Media Gateway)
- 1 VMM\_2BRI (2 port trunk-side integrated BRI Media Module)

---

## Error log entries and recommended actions

**Table 183: MG-BRI Error Log Entries 1 of 2**

| Error Type                 | Aux Data     | Associated Test                       | Alarm Level | On/Off Board | Recommended Action                    |
|----------------------------|--------------|---------------------------------------|-------------|--------------|---------------------------------------|
| 0 ( <a href="#">a</a> )    | 0            |                                       | Any         | Any          | <code>test board location</code>      |
| 1 ( <a href="#">b</a> )    | Any          | Sanity Failure                        | MIN         | ON           |                                       |
| 18                         |              | Media Module is busied out            |             |              | <code>release board location</code>   |
| 257 ( <a href="#">c</a> )  | 65535        | Control Channel Looparound Test (#52) | MIN         | ON           | <code>test board location r 20</code> |
| 513 ( <a href="#">d</a> )  | 4352 to 4357 | Angel Background Errors               |             | ON           | <code>test board location</code>      |
| 769 ( <a href="#">e</a> )  | 4358         | Program Logic Error                   |             |              |                                       |
| 1291 ( <a href="#">f</a> ) | 4359         | Clear Error Counters (#270)           | MIN         | ON           |                                       |
| 3586 ( <a href="#">g</a> ) |              |                                       | MIN         | OFF          |                                       |
| 3840 ( <a href="#">h</a> ) | 4096 to 4101 | Inconsistent Downlink Message         |             |              |                                       |
|                            |              |                                       |             |              | <b>1 of 2</b>                         |

**Table 183: MG-BRI Error Log Entries 2 of 2**

| Error Type | Aux Data | Associated Test         | Alarm Level | On/Off Board | Recommended Action |
|------------|----------|-------------------------|-------------|--------------|--------------------|
| 3842 (i)   | 46095    | Receive FIFO Overflow   |             |              |                    |
| 3843 (i)   | 46097    | Bad LAN Translation RAM |             |              |                    |
|            |          |                         |             |              | <b>2 of 2</b>      |

Notes:

- a. **Error Type 0:** run the short test sequence first. If every test passes, run the long test sequence. Refer to each test’s description, and follow its procedures.
- b. **Error Type 1:** the media module stopped functioning or is physically removed from the system. This alarm is logged approximately 11 minutes after removing the media module and/or the SAKI Sanity Test (#53) fails. If the media module is not in the system, insert a media module in the same slot as the error indicates. See note (f).
- c. **Error Type 257:** there are transient communication problems between the switch and this media module. Execute the `test board location` command and refer to the repair procedures for the [Control Channel Looparound Test \(#52\)](#).
- d. **Error Type 513:** on-board hardware failure. Aux data values correspond to the following detected errors:

| Aux Value | Detected Error           |
|-----------|--------------------------|
| 4352      | External RAM error       |
| 4353      | Internal RAM error       |
| 4355      | ROM checksum error       |
| 4357      | Message Corruption error |

Reset the media module with the `busyout board location` and `reset board location` commands. When reset, the media module executes a set of tests to detect the presence of any of the faults listed above. Detection of one of these errors during initialization causes the media module to lock-up and appear insane to the system.

- e. **Error Type 769:** the media module detects a program logic error. No action is required. However, this error can lead to other errors against this media module.
- f. **Error Type 1291:** the BRI Media Module detected a parity error while accessing its dynamic RAM which stores the board’s translation information and downloadable application firmware. Maintenance software resets the media module.

- g. **Error Type 3586:** the system detected an excessive number of uplink messages from the Media Module. To prevent the faulty board from flooding the switch with data, the switch software takes the board out of service and alarms it.

When the board is alarmed due to this error, the switch software periodically puts the board back in service and tells the Archangel to process uplink messages from the board. If the problem still exists, the software takes the media module out of service again. If the media module does not exhibit the problem for a certain time period, then maintenance software resolves the alarm and the media module is left in service.

- h. **Error Type 3840:** the media module received an inconsistent down-link message (a bad header, port number, data, sub-qualifier, or logical link) over the Control Channel. This is a notification only, and no action is required.
- i. **Error Type 3842:** the board is receiving data from the bus faster than it can distribute the data to its endpoints, causing the FIFO RAM buffer to overflow. This error can occur occasionally due to the statistical sizing of the buffers. If it occurs frequently, it may indicate a LAPD parameter mismatch. LAPD should recover from this problem, but it may degrade the performance of the LAN bus.
- j. **Error Type 3843:** bad translation RAM detected during call connection. The media module marks the location as bad and reports it. The call continues on a different port.

---

## Demand test descriptions and error codes

Investigate tests in the order presented. By clearing errors associated with the first test, errors generated from other tests may also be cleared. Click on the link to see the full description of the test, error codes, and recommended actions.

| Order of Investigation                                          | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|-----------------------------------------------------------------|---------------------|--------------------|-------------------|
| <a href="#">Control Channel Looparound Test (#52)</a>           | X                   | X                  | ND                |
| <a href="#">NPE Audit Test (#50)</a>                            |                     | X                  | ND                |
| <a href="#">LANBIC Receive Parity Error Counter Test (#595)</a> |                     | X                  | ND                |
|                                                                 |                     |                    |                   |

1. D = Destructive; ND = Nondestructive

## MG-DCP (Digital Line Media Module)

| MO Name in Log | Alarm Level | Initial Command to Run     | Full Name of MO           |
|----------------|-------------|----------------------------|---------------------------|
| MG-DCP         | MIN<br>WRN  | <i>test board location</i> | Digital Line Media Module |

The following is a list of supported DCP Media Modules:

- 1 MM312 (24 port DCP Media Module)
- 1 MM712 (8 DCP port Media Module)
- 1 MM717 (24 DCP port Media Module)
- 1 IMM\_DCP (Integrated DCP Media Module)

Maintenance software monitors and test ports on digital Media Modules and the hardware connected to those ports for lines administered as a digital station.

## Error log entries and recommended actions

**Table 184: MG-DCP Error Log Entries**

| Error Type     | Aux Data | Associated Test                                   | Alarm Level | On/Off Board | Recommended Action              |
|----------------|----------|---------------------------------------------------|-------------|--------------|---------------------------------|
| 0 <sup>1</sup> | 0        | Any                                               | Any         | Any          | <i>test board location</i>      |
| 1 (a)          | 0        | Media Module removed or SAKI Sanity Failure (#53) | MIN         | ON           |                                 |
| 18 (b)         | 0        | <i>busyout board location</i>                     | WRN         | OFF          | <i>release board location</i>   |
| 23 (c)         | 0        | None                                              | WRN         | OFF          |                                 |
| 125 (d)        |          | None                                              | MIN         | ON           |                                 |
| 257 (e)        | 65535    | Control Channel Looparound Test (#52)             | MIN         | ON           | <i>test board location r 20</i> |
| 513 (f)        | Any      | Angel Background Error                            | MIN         | ON           | <i>test board location</i>      |
| 769 (g)        | 4358     | None                                              |             |              |                                 |
| 1025 (h)       | 4363     | NPE Audit Test (#50)                              |             |              |                                 |
| 1281 (i)       |          | Ringling Application Test (#51)                   | MIN         | ON           | <i>test board location r 2</i>  |
| 1538 (j)       | Any      | None                                              | WRN<br>MIN  | ON           |                                 |

1. Run the short test sequence first. If every test passes, run the long test sequence. Refer to each appropriate test's description, and follow its recommended procedures.

Notes:

- a. **Error Type 1:** the media module stopped functioning or has been physically removed from the system. The alarm is logged approximately 11 minutes after removal of the media module or failure of the SAKI Sanity Test (#53).

Check for the physical presence of the media module in the slot indicated by the alarm. If the media module is absent, insert one of the proper type. If the media module is present and its red LED is lit, see LED alarms without Alarm Log entry or with Error Type 1 in *LED Descriptions for Avaya Aura™ Communication Manager Hardware Components (03-602804)*.

- b. **Error Type 18:** the media module has been busied out. Release the media module using **release board location**.

- c. **Error Type 23:** the media module has been logically administered but not physically installed. The alarm should clear when the media module is installed.

If the media module is already installed:

1. Run **test board location long** and look at any test failures or Error Codes generated.
2. If the test does not clear error 23, then execute **reset board location** and run the long test again.
3. If the reset/test does not clear error 23, replace the media module.

- d. **Error Type 125:** the media module physically installed in the slot does not match the type that is administered for that slot. Do one of the following:

1. Remove the incorrect media module and replace it with one of the type that is administered for that slot.
1. Use **change circuit-pack** or **change media-module** to re-administer the slot so that it matches the board that is installed, and follow with **reset board location**.

- e. **Error Type 257:** transient communication problems between the switch and this circuit pack or media module. Execute **test board location** and refer to the repair procedures for the [Control Channel Looparound Test \(#52\)](#).

- f. **Error Type 513:** an on-board hardware failure was detected. The system will continuously test the media module and report the results approximately every 10 minutes. If the hardware problem is resolved, the alarm should clear in approximately 30 minutes. If the alarm does NOT clear in 30 minutes, then the media module should be replaced.

- g. **Error Type 769:** this error can be ignored, but look for other errors on this media module.

- h. **Error Type 1025:** this error is not service-affecting and no action is required.

- i. **Error Type 1281:** this error is not service-affecting and no action is required.

- j. **Error Type 1538:** the hyperactive media module is out-of-service and may exhibit one or more of the following symptoms:

1. The media module level tests such as Test #51 and/or Test #220 are aborting with Error Code 2000.
2. The tests run on the ports of this media module are returning with a NO-BOARD.
3. A busyout/release of the media module has no effect on test results.
4. A `list configuration` command shows that the media module and ports are properly installed.

Check the alarm level. If the alarm level is a WARNING, users are probably causing the hyperactivity by adjusting or changing their digital stations. If the media module is very hyperactive, this alarm will be upgraded to a MINOR alarm within 1 hour. If the alarm level is a MINOR alarm, then replace the media module.

---

## Demand test descriptions and error codes

Investigate tests in the order presented. By clearing errors associated with the first test, errors generated from other tests may also be cleared. Click on the link to see the full description of the test, error codes, and recommended actions.

| Order of Investigation                                | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|-------------------------------------------------------|---------------------|--------------------|-------------------|
| <a href="#">Control Channel Looparound Test (#52)</a> | X                   | X                  | ND                |
| <a href="#">NPE Audit Test (#50)</a>                  |                     | X                  | ND                |

1. D = Destructive; ND = Nondestructive

## MG-DS1 (DS1 Interface Media Module)

| MO Name in Log | Alarm Level | Initial Command to Run                | Full Name of MO            |
|----------------|-------------|---------------------------------------|----------------------------|
| MG-DS1         | MAJ<br>MIN  | <code>test board location long</code> | DS1 Interface Media Module |
|                | WRN         | <code>test board location</code>      |                            |

The following is a list of supported DS1 Media Modules:

- 1 MM710 Universal DS1 Interface Media Module (1 T1/E1 ISDN PRI trunk port)
- 1 IMM\_DS1 Integrated DS1 Media Module
- 1 TIM510 DS1 Media Module for use in Juniper media gateways (1 T1/E1 port)

---

## Error log entries and recommended actions

**Table 185: MG-DS1 Error Log Entries 1 of 3**

| Error Type | Aux Data  | Associated Test                               | Alarm Level             | On/Off Board | Recommended Action                      |
|------------|-----------|-----------------------------------------------|-------------------------|--------------|-----------------------------------------|
| 0 (a)      | 0         | Any                                           | Any                     | Any          | <code>test board location</code>        |

| 3999 ( <a href="#">t</a> )         | Any      |                                    |                         |              |                                      |
|                                    |          |                                    |                         |              | <b>3 of 3</b>                        |

1. If ports are assigned to the Media Module, then a minor alarm is raised. If no ports are assigned to the Media Module, then a warning alarm is raised. The alarm is raised after the Media Module has been missing for a period of 15 minutes. Warning alarms are also raised against any ports administered on the Media Module.
2. Major alarms on this MO may be downgraded to minor or warning alarms, and minor alarms on this MO may be downgraded to warning alarms based on values set in `set options`.

**Notes:**

- a. **Error Type 0:** run the short test sequence first. If all tests pass, run the long test sequence. Refer to the appropriate test description and follow the recommended procedures.
- b. **Error Type 1:** the Media Module has totally stopped functioning or is not fully administered. The alarm is logged about 15 minutes after the Media Module has been removed or 11-minutes after the SAKI Test (#53) fails. To be fully administered, a Media Module must meet all three of the following conditions:
  1. Have an entry in the circuit plan using the `change media module` command

- | Be administered using the `add ds1 location` command
- | Be physically inserted into the correct slot

If the Media Module has an entry in the circuit plan and either of the other two conditions are *not* met, a MINOR alarm is logged.

1. To resolve the error do either of the following:
    - | Make sure that all conditions for administration are met and that a functioning Media Module is inserted in the correct slot.
    - | Completely remove the Media Module from the system using the following steps.
  2. Remove any administered DS1 trunks, access endpoints or PRI endpoints associated with the Media Module from their trunk groups.
  3. Execute `remove ds1 location` and `change media module location`.
- c. **Error Type 18:** the Media Module has been busied out by a `busyout board location` command. Release the Media Module with the command `release board location`.
- d. **Error Type 23:** the Media Module is not completely administered. To be fully administered, the Media Module must:
- | Have an entry in the circuit plan using the `change media module` command
  - | Be administered using the `add ds1 location` command
  - | Be physically inserted into the correct slot

A DS1 Media Module differs from most Media Modules in that inserting the DS1 Media Module into the media gateway is not enough to make the board usable. It must also be administered with the `add ds1` command.

- e. **Error Type 125:** An incorrect Media Module is inserted in the slot where the Media Module is logically administered.

To resolve this problem, either:

- | Remove the incorrect Media Module and insert the logically administered Media Module.
  - | Use the `change circuit-pack` command to re-administer this slot to match the Media Module inserted.
- f. **Error Type 257:** Refer to [Control Channel Looparound Test \(#52\)](#) for details.
- g. **Error Type 513:** the Media Module has detected a transient hardware problem.

The value in the Aux Data field indicates the type of hardware problem:

Aux Data 4352: External RAM failure

Aux Data 4353: Internal RAM failure

Aux Data 4355 Internal ROM failure

If the board detects only one of these hardware problems, the error will disappear when none of these faults are detected for 10 minutes. If the same Aux Data value is logged more than once in a 24 hour period, the Media Module should be replaced.

**h. Error Type 514:** LAN External RAM Error.

This error occurs when there is a hardware fault in the PPE external RAM. The RAM is used for message buffering to and from the Packet Bus. This error should not occur frequently. If it does (at least 10 times within 30 minutes), the Media Module should be replaced.

**i. Error Type 769:** transmit FIFO Underflow Error.

This error occurs when the Media Module cannot find the end of frame bit when transmitting a frame to the Packet Bus. An alarm is raised if this error occurs three times within 10 minutes. Clear the alarm using the following commands: `busyout board location`, `reset board location`, `test board location long`, `release board location`. If the error recurs within 10 minutes, replace the Media Module.

**j. Error Type 770:** Unable to Write LAN Translation RAM Error.

This error occurs when there are no available translation RAM locations for a call connection attempt. An alarm is raised if this error occurs twice within 10 minutes. Clear the alarm using the following commands: `busyout board location`, `reset board location`, `test board location long`, `release board location`. If the error recurs within 10 minutes, replace the Media Module.

**k. Error Type 1025:** This error is not service-affecting and no action is required.

**l. Error Types 1400, 1401:** Echo Cancellation error.

Echo Cancellation errors are logged when:

- 1 Error 1400 -The Echo Canceller Function Test failed.
- 1 Error 1401 -The Echo Canceller Memory Test failed.

This error indicates that Echo Cancellation is no longer being supplied by the board. Clear the alarm using the following commands: `busyout board location`, `test board location long`, `release board location`. If Test #1420 (Echo Canceller Test) fails, replace the Media Module.

**m. Error Type 1537:** LAN Bus Timeout Error.

This error occurs when the Media Module transmits too many bytes on the LAN bus for a single frame. This condition may be caused by an on-board fault or by faulty data received on one of the Media Module's external ports. If any of the ports on this Media Module are alarmed, refer to the repair procedures for those maintenance objects.

If the error occurs three times within 10 minutes, the board is isolated from the Packet Bus and the board is alarmed. To clear the alarm and restore the board to the Packet Bus, use the commands `busyout board location`, `reset board location`, `test board location long`, `release board location`.

If the problem persists and there are no PKT-BUS alarms or port alarms, replace the Media Module.

**n. Error Type 1538:** The hyperactive Media Module is out-of-service and may exhibit one or more of the following symptoms:

- | The common Media Module level tests such as Test #50 abort with Error Code 2000.
- | The tests run on the ports of this Media Module return NO-BOARD.
- | A busyout/release of the Media Module has no affect on test results.
- | A **list configuration** command shows that the Media Module and ports are properly installed.

The Media Module is isolated from the system and all trunks or ports on this Media Module are placed into the out-of-service state. The system will try to restore the Media Module within 20-30 minutes. When no faults are detected for 20-30 minutes, the Media Module is restored to normal operation. All trunks or ports of the Media Module are then returned to the in-service state.

If the board is not restored to normal operation, or the error recurs after the board was restored to normal operation, escalate the problem.

- o. **Error Types 3073 to 3160**: the Media Module is receiving slips. The Error Type displays the value of the last slip count reported.
- p. **Error Types 3585 to 3601**: the Media Module is receiving misframes. The Error Type displays the value of the last misframe count reported.
- q. **Error Type 3840**: is not service-affecting. No action is required.
  - These errors are reported by the Media Module when it receives a bad control channel message from the switch. The Aux Data identifies the cause of the error event.
- r. **Error Type 3841**: The Media Module has detected a transient hardware logic error. This error will disappear when no faults are detected for 100 minutes.
- s. **Error Type 3842**: Bad Translation RAM Location Found. This error is not service-affecting. No action is required. The call continues by using another translation location.
- t. **Error Type 3999**: the Media Module sent a large number of control channel messages to the switch within a short period of time.

If **Error Type 1538** is also present, the Media Module was taken out-of-service due to hyperactivity. If Error Type 1538 is not present, the Media Module has not been taken out-of-service, but it has generated 50% of the messages necessary to be considered hyperactive. This may be completely normal during heavy traffic periods. However, if this Error Type is logged when the Media Module is being lightly used, it may indicate a problem with the Media Module or the equipment attached to it.

## Demand test descriptions and error codes

Investigate tests in the order presented. By clearing errors associated with the first test, errors generated from other tests may also be cleared. Click on the link to see the full description of the test, error codes, and recommended actions.

| Order of Investigation                                   | Short Test Sequence | Long Test Sequence | Reset Board Sequence | test ds1-loop | D/ND <sup>1</sup> |

1. D = Destructive; ND = Nondestructive

## MG-IAMM (Integrated Analog Media Module)

| MO Name in Log | Alarm Level | Initial Command to Run                | Full Name of MO                |
|----------------|-------------|---------------------------------------|--------------------------------|
| MG-IAMM        | MIN         | <code>test board location long</code> | Integrated Analog Media Module |
|                | WRN         | <code>test board location</code>      |                                |

The MG-IAMM Maintenance Object resides on the Integrated Analog Media Module (IAMM) which is located on the main board of the G250, G250-BRI, G250-DCP, G250-DS1, G350, and TGM550 media gateways.

The Integrated Analog Media Module is not field-replaceable.

For the G250, the Integrated Analog Media Module consists of six (6) fixed configuration analog ports:

- 1 Ports 1 through 4 are fixed as loop start CO trunk ports.
- 1 Ports 5 and 6 may be administered as analog stations, DID trunks, or external alarm ports.
- 1 Ports 4 and 5 are used by the media gateway processor for emergency transfer relay (ETR) purposes.

The Integrated Analog Media Module is a non-field-replaceable module. Slot #3 is virtual and designated as the integrated analog media module slot. Slot #3 supports the IAMM exclusively.

For the G250-BRI and G350, the Integrated Analog Media Module consists of three (3) fixed configuration analog ports:

- 1 Port 1 is fixed as an analog trunk port.
- 1 Ports 2 and 3 are fixed as analog line ports.
- 1 Ports 1 and 2 are used by the media gateway processor for emergency transfer relay (ETR) purposes.

On a G250-BRI, slot #3 is virtual and designated as the integrated analog media module slot.

On a G350, slot #7 is virtual and designated as the integrated analog media module slot.

Administration will only allow port one to be administered as a loop start CO trunk. Ports 2 and 3 may only be administered as analog stations, DID trunks, or external alarm ports. Ports 1 and 2 are used by the emergency transfer relay (ETR).

The TGM550 is the Media Gateway blade which is integrated with the Juniper Networks Services Routers. It provides an internal interface to the Juniper chassis backplane, 2 analog lines, and 2 analog trunks. Ports 2 and 3 are used by the emergency transfer relay (ETR).

The G250-DCP allows 4 trunks and 2 analog lines. Ports 4 and 5 are used by the ETR.

The G250-DS1 allows 1 trunk and 2 analog lines. Ports 1 and 2 are used by the ETR.

See [XXX-BD \(Common Port Circuit Pack/Media Module\)](#) for media module level errors.

For individual port problems see the relevant MO:

- 1 If the port is administered as a CO trunk, see [CO-TRK \(Analog CO Trunk\)](#).
- 1 If the port is administered as a DID trunk, see [DID-TRK \(Direct Inward Dial Trunk\)](#).
- 1 If the port is administered as a CAMA/E911 trunk, see [DIOD-TRK \(DIOD Trunk\)](#).
- 1 If the port is administered as an analog line, see [AN-LN-PT \(Analog Line Port\)](#).
- 1 If the port is administered as an external device alarm, see [ALARM-PT \(Alarm Port\)](#).
- 1 If the port is administered as an analog endpoint, see [ANL-LINE \(8-Port Analog Line\)](#).

## Error log entries and recommended actions

**Table 186: MG-IAMM Error Log Entries**

| Error Type | Aux Data | Associated Test                 | Alarm Level | On/Off Board | Recommended Action              |
|------------|----------|---------------------------------|-------------|--------------|---------------------------------|
| 1 (a)      | 0        | Sanity Failure                  | MIN         | ON           |                                 |
| 18 (b)     | 0        | busyout location                |             | OFF          | <i>release location</i>         |
| 23 (c)     |          |                                 | WRN         | OFF          |                                 |
| 257 (d)    | 65535    | Control Channel Looparound Test | MIN         | ON           | <i>test board location r 20</i> |
| 513 (e)    | Any      |                                 | MIN         | ON           |                                 |
| 769 (f)    | 4358     |                                 |             |              |                                 |

Notes:

- a. **Error Type 1:** the Integrated Analog Media Module (IAMM) has stopped functioning or was physically removed from the system. This alarm is logged 11 minutes after removing the media module or the SAKI Sanity Test fails. NOTE: The IAMM is not removable. This error indicates that there may be a firmware or hardware problem with the media gateway.
  1. Reset the Integrated Analog Media Module with `reset board <location>`.
  2. Retest the board using `test board location`.
  3. If this error persists, replace the media gateway.
- b. **Error Type 18:** the indicated Integrated Analog Media Module circuit has been made unavailable with the `busyout location` command. To resolve this error, enter `release location` for the alarmed media module.

- c. **Error Type 23:** the media module has been administered but is not inserted. Because this is an integrated media module, there may be a hardware or firmware problem with the media gateway main board.
1. Reset the Integrated Analog Media Module with `reset board <location>`. Use `list configuration media-gateway location` to verify whether or not the IAMM is inserted.
    - For the G250, the code field for slot 3 should indicate **4T2LIM**
    - For the G250-BRI, the code field for slot 3 should indicate **1T2LIM**
    - For the G350, the code for slot 7 should indicate **1T2LIM**
    - For the TGM550, any slot may indicate the code **TGM550**
  2. Verify that the latest version of firmware is present on the media gateway main board. Use `show mg list_config`. Upgrade the firmware if necessary.
  3. If the problem persists, replace the media gateway.
- d. **Error Type 257:** test #52 failed. This error will clear when the test passes.
- e. **Error Type 513:** the IAMM circuitry detected a memory error during its background self-test diagnostics (External RAM failure, Internal RAM failure, ROM checksum failure, Message corruption). This error indicates the IAMM is running corrupted code.
1. Download and install the appropriate firmware on the media gateway.
  2. If the problem persists, replace the media gateway.
- f. **Error Type 769:** the integrated analog media module detected an internal consistency. This error can be ignored and no action is required.

---

## Demand test descriptions and error codes

Investigate tests in the order presented. By clearing errors associated with the first test, errors generated from other tests may also be cleared. Click on the link to see the full description of the test, error codes, and recommended actions.

| Order of Investigation                                | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|-------------------------------------------------------|---------------------|--------------------|-------------------|
| <a href="#">NPE Audit Test (#50)</a>                  |                     | X                  | ND                |
| <a href="#">Ringing Application Test (#51)</a>        | X                   | X                  | ND                |
| <a href="#">Control Channel Looparound Test (#52)</a> | X                   | X                  | ND                |
|                                                       |                     |                    |                   |

1. D = Destructive; ND = Nondestructive

## MG-IBRI (Integrated BRI Trunk Media Module)

| MO Name in Log | Alarm Level | Initial Command to Run                | Full Name of MO                   |
|----------------|-------------|---------------------------------------|-----------------------------------|
| MG-IBRI        | MIN         | <code>test board location long</code> | Integrated BRI Trunk Media Module |

The MG-IBRI maintenance object resides on the virtual ISDN trunk-side BRI media module. It has two ports which can either be administered as a trunk-side BRI port or BRI trunk.

MG-IBRI has the same maintenance strategy as the MG-BRI media module. See [MG-BRI \(BRI Trunk Media Module\)](#) for the error codes, tests, and recommended actions.

## MG-VOIP (MM760 VoIP Media Module)

| MO Name in Log | Alarm Level | Initial Command to Run     | Full Name of MO               |
|----------------|-------------|----------------------------|-------------------------------|
| MG-VOIP        | MIN<br>WRN  | <i>test board location</i> | Voice Over IP<br>Media Module |

The MM760 Media Module provides the audio bearer channels for Voice over IP calls, and is under control of the G700. One MM760 Media Module has one VoIP-MM media processing resource. Based on system administration of audio codecs, a VoIP-MM can handle either 64 or 32 simultaneous channels of H.323 audio processing. The VoIP-MM can service 64 channels if the **IP Parameters** form specifies only G.711 mu-law or G.711 a-law as the audio codecs. If any other codec type (G.723-5.3K, G.723-6.3K, or G.729) is administered, the VoIP-MM can only service 32 channels.

---

## Error log entries and recommended actions

**Table 187: MG-VOIP Error Log Entries**

| Error Type | Aux Data | Associated Test                       | Alarm Level | On/Off Board | Recommended Action               |
|------------|----------|---------------------------------------|-------------|--------------|----------------------------------|
| 0 (a)      | 0        | Any                                   | Any         | Any          | <i>test board location</i>       |
| 257 (b)    | 65535    | Control Channel Looparound Test (#52) | MIN         | ON           | <i>test board location 1 r 2</i> |

Notes:

- a. **Error Type 0**: run the short test sequence first. If every test passes, run the long test sequence. Refer to each test's description, and follow its procedures.
- b. **Error Type 257**: refer to [Control Channel Looparound Test \(#52\)](#) and follow the recommended procedures.

---

## Demand test descriptions and error codes

| Order of Investigation                                | Short Test Sequence | Long Test Sequence | D/ND |
|-------------------------------------------------------|---------------------|--------------------|------|
| <a href="#">Control Channel Looparound Test (#52)</a> | X                   | X                  | ND   |

## MIS (Management Information System)

| MO Name in Log | Alarm Level | Initial Command to Run   | Full Name of MO               |
|----------------|-------------|--------------------------|-------------------------------|
| MIS            | WRN         | <code>release mis</code> | Management Information System |

Use the Management Information System (MIS)/Call Management System (CMS) to monitor MIS busyouts during administration of MIS translations. There are no hardware failures associated with this MO.

The MIS/CMS is an adjunct processor that collects Automatic Call Distribution (ACD) data sent from the switch. In order to change MIS translations, enter `busyout mis` at the G3-MT. When the MIS is busied out, the switch stops sending ACD data to the MIS, and a Warning alarm is raised.

When the `busyout mis` is complete, enter `release mis` at the terminal. This clears the Warning alarm and allows the switch to send ACD data to the MIS.

---

## Error log entries and recommended actions

**Table 188: MIS Error Log Entries**

| Error Type | Aux Data | Associated Test          | Alarm Level | On/Off Board | Recommended Action       |
|------------|----------|--------------------------|-------------|--------------|--------------------------|
| 0 (a)      | 0        | Any                      | Any         | Any          | <code>release mis</code> |
| 18 (b)     | 0        | <code>busyout mis</code> | WRN         | ON           | <code>release mis</code> |

Notes:

- a. **Error Type 0:** run the short test sequence first. If every test passes, run the long test sequence. Refer to each test's description, and follow its procedures.
- b. **Error Type 18:** with `busyout mis`, no data is sent to the MIS/CMS regardless of the link state. To allow data to be sent to MIS/CMS, use `release mis` at the terminal.

## MMI-BD (Multimedia Interface Circuit Pack)

| MO Name in Log      | Alarm Level | Initial Command to Run                | Full Name of MO                   |
|---------------------|-------------|---------------------------------------|-----------------------------------|
| MMI-BD              | MAJ<br>MIN  | <code>test board location long</code> | Multimedia Interface circuit pack |
| MMI-BD <sup>1</sup> | WRN         | <code>test board location</code>      |                                   |

1. Refer to [XXX-BD \(Common Port Circuit Pack/Media Module\)](#).

Two circuit packs can be used for multimedia connections:

- 1 [TN787D \(or later\)](#)
- 1 [TN2207/Expansion Services Module](#)

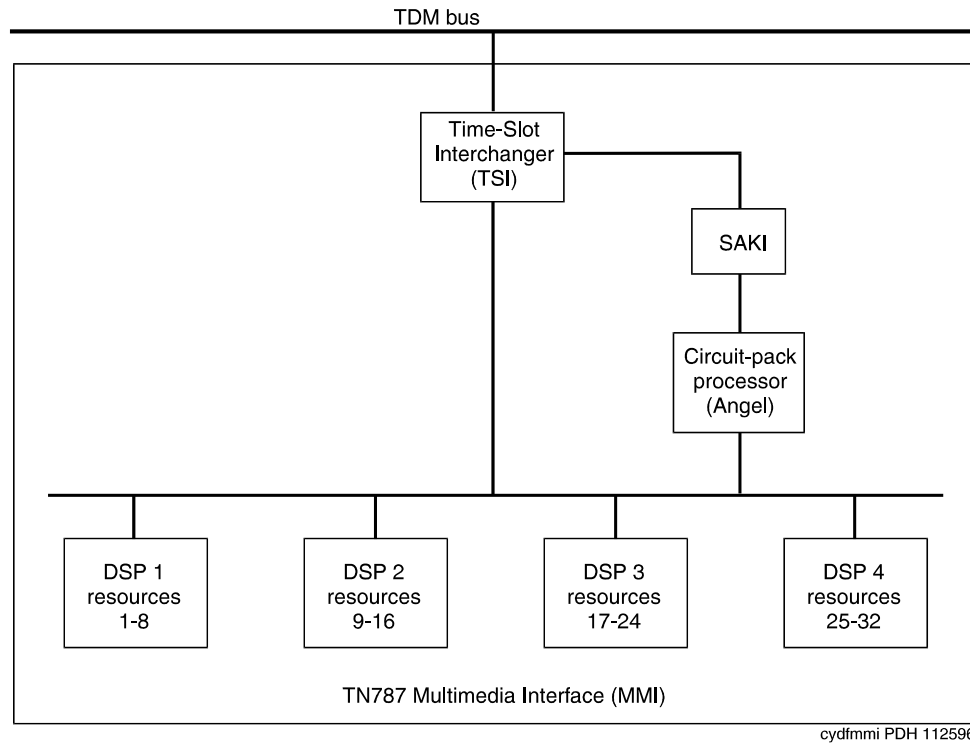

### TN787D (or later)

The Multimedia Interface circuit pack (TN787D or later, also called the MMCH circuit pack) provides a number of H.221 protocol terminations for bit streams received from the TDM bus. The Multimedia Interface de multiplexes the H.221 bit stream (audio, video, data, control, and indication signals) and transmits the bit streams onto the TDM bus so that the appropriate circuit packs can process them.

The Multimedia Interface circuit pack is commonly referred to as the MMI pack for H.221 protocol termination. There are 32 ports (also called resources) on the circuit pack. See [MMI-PT \(Multimedia Interface Port\)](#) for maintenance of these resources.

The MMI circuit pack contains 4 digital signal processors that manage the 32 resources.

Figure 43: TN787 Multimedia Interface (MMI) Circuit Pack

## TN2207/Expansion Services Module

The TN2207 circuit pack permits connecting an ESM (Expansion Services Module). See [Figure 44: Typical ESM connections](#) for connectivity.

- 1 The TN2207 circuit pack provides T.120 data-sharing capability on a MMCH multipoint H.320 video conference
- 1 Each conference participant must have endpoints administered and a personal computer with the H.320 video application installed.
- 1 The S8700 Media Server configuration must have an expansion service module installed.

**Figure 44: Typical ESM connections**

**Figure notes:**

1. Port B Y-cable connector to a TN787 MMI (Multimedia Interface) circuit pack
2. Port A Y-cable connector to a TN2207 PRI circuit pack
3. 25-pair Y-cable
4. 356A adapter
5. D8W cord connected to 356A adapter port 1
6. Expansion Service Module (ESM)
7. Port B on compatible PRI (primary rate interface) card

**⚠ CAUTION:**

The TN2207 circuit pack is the only pack that allows connection of an ESM to S8700 Media Server configurations.

## Error log entries and recommended actions

**Table 189: MMI-BD Error Log Entries 1 of 2**

| Error Type | Aux Data     | Associated Test                       | Alarm Level | On/Off Board | Recommended Action             |

| 1793 (j)   | Any      | NPE/TSI Crosstalk Test (#6)      | MIN         | ON           | <i>test board location 1 r 3</i> |
| 2049 (k)   | Any      | TSI Loop (#1108)                 | MAJ         | ON           | <i>test board location 1 r 3</i> |
|            |          |                                  |             |              | <b>2 of 2</b>                    |

## Notes:

- a. **Error Type 0:** run the short test sequence first. If every test passes, run the long test sequence. Refer to each test's description, and follow its procedures.
- b. **Error Type 1:** the circuit pack stopped functioning or it was physically removed from the system. The alarm logs approximately 11 minutes after the circuit pack has been removed and/or the SAKI Sanity test (#53) fails.  
  
If the circuit pack is in the system and the red LED is on, follow the instructions for a red alarm in the Circuit Pack LEDs section of *LED Descriptions for Avaya Aura™ Communication Manager Hardware Components (03-602804)*.
- c. **Error Type 18:** the circuit pack was busied out using *busyout board location*.
- d. **Error Type 217:** there are more than four MMI circuit packs in the system. Remove the circuit pack that generated the error in the error log by locating the slot indicated by the error.
- e. **Error Type 257:** there are transient communication problems between the switch and this circuit pack. Execute *test board location* and see the repair procedures for the [Control Channel Looparound Test \(#52\)](#).
- f. **Error Type 513:** the circuit pack detected an Angel on-board hardware failure. The reported Aux Data values correspond to the following detected errors:
  - 4352 — External RAM error
  - 4253 — Internal RAM error
  - 4355 — ROM Checksum error
  - 4357 — Instruction set error

Use **busyout board location**, **reset board location**, and **release board location**. When reset, the circuit pack executes a set of tests to detect the presence of any of the above faults. The detection of one these errors during initialization causes the circuit pack to lock up and appear insane to the system. See the repair procedures in Note (b) for Error Type 1.

- g. **Error Type 769**: this MMI circuit pack reported a loss of MMI synchronization. Refer to [MMI Update Synchronization Status Test \(#1123\)](#) for repair procedures.
- h. **Error Type 1281**: a failure of the time slot interchanger was detected. Reset the circuit pack using **busyout board location**, **reset board location**, and **release board location**. If the reset passes, then the on-board circuitry is healthy. Retire the alarm using **test board location long clear** followed by **release board location**.
- i. **Error Type 1538**: the circuit pack is hyperactive and it is flooding the switch with messages sent over the control channel. The circuit pack is taken out-of-service when a threshold number of these errors is reported to the switch. Clear the alarm using **busyout board location**, **reset board location**, **test board location long clear**, and **release board location**. If the error recurs within 10 minutes, replace the circuit pack.
- j. **Error Type 1793**: the NPE/TSI Crosstalk test (#6) failed. See [NPE Crosstalk Test \(#6\)](#), and follow its repair procedures.
- k. **Error Type 2049**: the TSI Looparound test (#1108) failed. See [TSI Looparound Test \(#1108\)](#), and follow its repair procedures.

---

## Demand test descriptions and error codes

Investigate tests in the order presented. By clearing errors associated with the first test, errors generated from other tests may also be cleared. Click on the link to see the full description of the test, error codes, and recommended actions.

| Order of Investigation                                         | Short Test Sequence | Long Test Sequence | Reset Board Sequence | D/ND <sup>1</sup> |

## MMI-LEV (Multimedia Interface Resource Level)

| MO Name in Log | Alarm Level | Initial Command to Run                                | Full Name of MO                     |
|----------------|-------------|-------------------------------------------------------|-------------------------------------|
| MMI-LEV        | MAJ         | See <a href="#">Resolving MMI-LEV Errors/Alarms</a> . | Multimedia Interface Resource Level |

The Multimedia Interface Resource Level MO monitors MMI efficiency by tracking the number of MMI ports that are in-service and comparing that number with the value entered in the **MMIs** field on the System-Parameters Maintenance screen. This **MMIs** field is located under the Minimum Maintenance Threshold section. The **MMIs** field contains the minimum number of MMI ports needed for the Multimedia Call Handling (MMCH) feature to run efficiently and is an administrable field. This field must contain a minimum threshold number for MMI port capacity of between 0-128. The MMCH feature must be enabled on the System-Parameters Customer-Options screen before the **MMIs** field can be changed to a number greater than zero.

Each MMI circuit pack contains up to 32 ports. If the number of in-service MMI ports falls below the minimum port capacity, an MMI-LEV error is logged. If this outage continues for 15 minutes, a MAJOR alarm is raised.

---

## Resolving MMI-LEV Errors/Alarms

MMI ports are a key part of the MMCH feature, and any loss in the number of ports available for use degrades the MMCH customer-defined service level.

If a MMI circuit pack or port is busied out using **busyout board** or **busyout port**, these out-of-service ports are not included in the MMI level calculation, thus allowing a technician to busyout a MMI circuit pack for maintenance reasons without causing a MAJOR alarm to be raised. However, if every port on the MMI circuit pack is not made busy and the circuit pack is removed, an alarm is raised.

### Note:

When diagnosing a MMI-LEV problem, begin by resolving any alarms raised against MMI-BD or MMI-PT MOs. Clearing MMI-BD or MMI-PT alarms may clear the MMI-LEV alarm.

The MMI circuit pack can be removed and reinserted in any port board slot without administration. Similarly, if a MMI circuit pack is removed from service logically by failing the Archangel sanity scan test or is removed from service physically by removing the circuit pack from the carrier, no error/alarm is raised against either the MMI-BD or the MMI-PT MOs. If a MMI-LEV error/alarm exists, yet no alarms have been raised against MMI-BD or MMI-PT MOs, a MMI circuit pack may have been removed from service, causing the MMI-LEV error/alarm. To resolve a MMI-LEV MAJOR alarm, restore the number of MMI ports available for service to be equal to or greater than the calculated port capacity.

To determine how many MMI circuit packs are needed for the MMCH feature:

1. Using `display system-parameters maintenance`, locate the number listed in the Minimum Maintenance Thresholds (**MMIs**) field and record this number.
2. Use `list configuration` to verify the number of MMI ports.
3. Compare this number with the value listed in the **MMIs** field on the **System-Parameters Maintenance** screen (number listed in step 1: minimum thresholds number for MMI ports of between 0-128). Each MMI circuit pack contains up to 32 ports. If this number in the **MMIs** field is less than or equal to 32, one MMI circuit pack is needed. If this number is 64, then two MMI circuit pack are needed.
4. Use `list configuration` to verify that the number of MMI circuit packs listed agrees with the required minimum port capacity (from step 1). If the number of MMI circuit packs listed in the step 2 differs from the calculated number, restore the number of MMI circuit packs to the correct value, in order to resolve the MMI-LEV alarm.

---

## Error log entries and recommended actions

**Table 190: MMI-LEV Error Log Entries**

| Error Type | Aux Data | Associated Test | Alarm Level | On/Off Board | Recommended Action |
|------------|----------|-----------------|-------------|--------------|--------------------|
| 1 (a)      | Any      | None            | MAJ         | OFF          |                    |

Notes:

- a. **Error Type 1:** The number of MMI resources in the system that are in service has fallen below the calculated minimum value. If the number of in-service MMI ports falls below the MMCH port capacity (value entered in the Minimum Maintenance Thresholds for **MMIs** field) on the System-Parameters Maintenance screen, an MMI-LEV error is logged. If this outage continues for 15 minutes, a MAJOR alarm is raised.
  1. See [MMI-PT \(Multimedia Interface Port\)](#) and [MMI-BD \(Multimedia Interface Circuit Pack\)](#) and resolve any associated alarms.
  2. If an MMI-LEV error/alarm exists and none has been raised against MMI-BD or MMI-PT MOs, an MMI circuit pack may have been removed from service causing the MMI-LEV error/alarm. Restore the number of MMI ports available for service to be equal to or more than the calculated port capacity. See [Resolving MMI-LEV Errors/Alarms](#) for details.
  3. If this error continues, escalate the problem.

---

## Demand test descriptions and error codes

There are no demand tests for MMI-LEV.

## MMI-PT (Multimedia Interface Port)

| MO Name in Log | Alarm Level       | Initial Command to Run               | Full Name of MO           |
|----------------|-------------------|--------------------------------------|---------------------------|
| MMI-PT         | MAJ<br>MIN<br>WRN | <code>test port location long</code> | Multimedia Interface Port |

**Note:**

Refer to [Chapter 4: General troubleshooting](#) in *Maintenance Procedures (03-300432)* for MMCH troubleshooting information.

The Multimedia Interface circuit pack provides a number of H.221 protocol terminations for bit streams received from the TDM bus. The Multimedia Interface demultiplexes the H.221 bit stream (audio, video, data, control, and indication signals) and transmits the bit streams onto the TDM bus to be processed by the appropriate circuit packs.

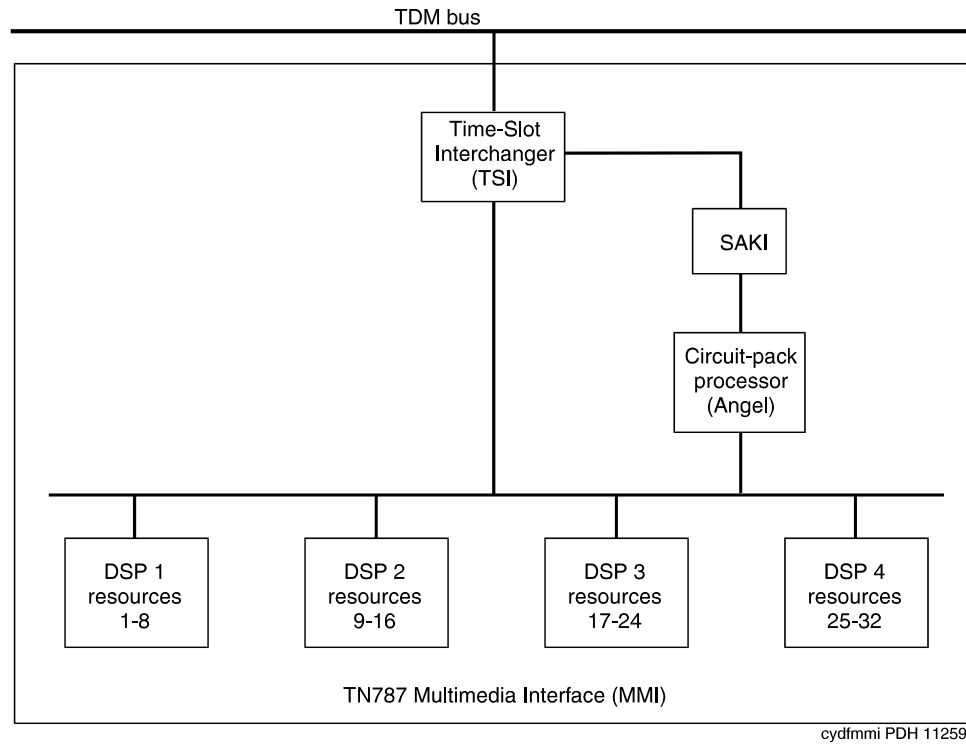

Each Multimedia Interface circuit pack contains 32 separately maintained “ports,” more commonly referred to as “resources.” MMI-PT represents one of these 32 resources. At system boot or when the circuit pack is inserted, 32 resources are inserted into the system.

The MMI circuit pack contains 4 Digital Signal Processors (DSPs) which manage the 32 resources. These resources are directly mapped to DSPs:

| Resource | Direct Map |
|----------|------------|
| 1–8      | DSP1       |
| 9–16     | DSP2       |
| 17–24    | DSP3       |
| 25–32    | DSP4       |

All 8 resources that the circuit pack controls may be placed out of service by the failure of one of these DSPs.

Figure 45: TN787 MMI (MULTIMEDIA INTERFACE) CIRCUIT PACK

## Error log entries and recommended actions

Table 191: MMI-PT Error Log Entries 1 of 2

| Error Type | Aux Data | Associated Test              | Alarm Level | On/Off Board | Recommended Action           |
|------------|----------|------------------------------|-------------|--------------|------------------------------|
| 0 (a)      | 0        | Any                          | Any         | Any          | <i>test port location</i>    |
| 1 (b)      | Any      | Uplink error from pack       |             |              |                              |

|            |          |                              |             |              | <b>1 of 2</b>                |

**Table 191: MMI-PT Error Log Entries 2 of 2**

| Error Type       | Aux Data | Associated Test                | Alarm Level | On/Off Board | Recommended Action            |
|------------------|----------|--------------------------------|-------------|--------------|-------------------------------|
| 513 (f)          | Any      | Resource Loopback test (#1111) | MIN         | ON           | <i>test port location r 3</i> |
| 1025 (g)         | Any      | Uplink error from pack         |             |              |                               |
| 3841 to 3844 (h) | Any      | Uplink error from pack         |             |              |                               |
|                  |          |                                |             |              | <b>2 of 2</b>                 |

Notes:

- a. **Error Type 0:** run the short test sequence first. If every test passes, run the long test sequence. Refer to each test's description and follow its procedures.
- b. **Error Type 1:** the customer endpoint connected on a conference sent too many messages to the VSP-MCU in a specified amount of time. Check **status conference** to correlate which customer had the problem. This is a customer endpoint problem, not a VSP-MCU problem.
- c. **Error Type 18:** this port was busied out by **busyout port location**.
- d. **Error Type 130:** the circuit pack was removed or has been insane for more than 11 minutes. To clear the error, replace or reseal the circuit pack.
- e. **Error Type 257:** the MMI circuit pack detects a DSP Error. Maintenance software resets the DSP when this error is received. This error is logged for all 8 resources connected to this particular DSP. If this DSP continues to fail sanity, a Minor alarm is raised. Replace the circuit pack.
- f. **Error Type 513:** the Resource Loopback test (#1111) fails. Run the long test sequence, and note the results of the [Resource Looparound Test \(#1111\)](#).
- g. **Error Type 1025:** either the MMI or Voice Conditioner (VC) circuit packs reports a loss of framing on the service channel between these two circuit packs. When a customer endpoint establishes a call to the VSP-MCU, a channel is established between the MMI resource and the VC port. If this channel is detected to go down by either circuit pack, an uplink message is sent. This error is then forwarded to maintenance for both circuit packs. Run the long test sequence for this MMI resource, and if any of the tests fail, follow the repair procedures for that test. If every test passes, the cause of the problem might be with the VC pack. See the repair procedures in [VC-DSPPT \(Voice Conditioner DSP Port\)](#).

- h. **Error Types 3841 - 3844:** are not related to VSP-MCU. They could be caused by network problems or from the customer endpoints. They are presented here for logging purposes only.

| Code | Description                                                                      |
|------|----------------------------------------------------------------------------------|
| 3841 | CRC4 Error (Frame checksum error)                                                |
| 3842 | Correctable BAS (Control msg bit error – 1- or 2-bit error, correctable)         |
| 3843 | Uncorrectable BAS (Control msg bit error – 3-bit error or more, not correctable) |
| 3844 | Protocol Error (H.221 Protocol error from endpoint detected)                     |

---

## Demand test descriptions and error codes

| Order of Investigation                           | Short Test Sequence | Long Test Sequence | D/ND        |
|--------------------------------------------------|---------------------|--------------------|-------------|
| <a href="#">Resource Looparound Test (#1111)</a> | X                   | X                  | Destructive |

## MMI-SYNC (MMI Synchronization)

| MO Name in Log | Alarm Level | Initial Command to Run                | Full Name of MO                   |
|----------------|-------------|---------------------------------------|-----------------------------------|
| MMI-SYNC       | MIN         | <code>test board location long</code> | Multimedia Interface circuit pack |

**Note:**

Refer to [Chapter 4: General troubleshooting](#) in *Maintenance Procedures (03-300432)* for MMCH troubleshooting information.

Each Port Network (PN) must have a TN787D or later MMI circuit pack assigned as the Multimedia Interface (MMI) master synchronization source for that PN. If one or more MMI circuit pack is administered in a PN, one MMI circuit pack is designated as the master synchronization source for every MMI circuit pack within that PN.

The MMI circuit pack generates a synchronization signal and puts that signal on the TDM bus. Other MMI packs or any other circuit pack within a PN can listen to this signal and “synchronize up” to it. The first MMI circuit pack inserted in a PN is normally designated as the master. As subsequent MMI packs are inserted, they are instructed to listen and synchronize to the time-slot of the master MMI. In the unlikely case of an MMI losing this reference, an uplink message is sent from the MMI circuit pack that lost the signal to maintenance, which also clears the “event” counter on this MMI with a downlink message. This forces the MMI circuit pack to return the current state of the synchronization signal. If the signal is still lost, then the recovery algorithm is entered. Note that during this time, the MMI circuit pack synchronizes to its internal clock, and there should be no service disruption. A loss of synchronization is usually the result of a circuit pack failure. The maintenance strategy is to switch the master source away from the bad pack to another healthy MMI circuit pack within the PN.

A synchronization switch takes place if half or more of the MMI circuit packs in a PN report a loss of synchronization. For example, a PN with two MMIs reporting a loss of sync source switches immediately, three and four MMIs switch if two report the loss, and so forth. A healthy MMI circuit pack becomes the master synchronization source providing the signal on a new timeslot. The other MMI circuit packs within the PN are instructed to listen to this new signal, and the old master stops providing the signal and now listens to the new master MMI. If an MMI is physically removed from the system, then the remaining MMIs report the loss of synchronization. The first MMI with no alarms present becomes the new master of that PN. Once a synchronization switch has occurred, another switch is not allowed for 15 minutes to avoid hyperactive switching. If every MMI has an alarm, then no switch is made.

If the MMI circuit pack that provides synchronization is craft busied out, it will not affect the PN synchronization. The signal is still provided by the busied-out pack. There is no effect on synchronization if the technician enters a release of the busied-out MMI. Synchronization is not affected by a warm start of the system (reset system 1). For every other restart (reboot through cold 2), MMI synchronization recovers during board insertion.

---

## Error log entries and recommended actions

Table 192: MMI-SYNC Error Log Entries

| Error Type | Aux Data | Associated Test | Alarm Level | On/Off Board | Recommended Action |
|------------|----------|-----------------|-------------|--------------|--------------------|
| 1 (a)      | Any      | None            |             |              |                    |
| 257 (b)    | Any      | None            | MIN         | OFF          |                    |

Notes:

- a. **Error Type 1:** an MMI synchronization switch was successful.
  1. Refer to [MMI-BD \(Multimedia Interface Circuit Pack\)](#) errors for the reason for the switch.
- b. **Error Type 257:** the requested MMI synchronization switch failed.
  1. Resolve every [MMI-BD \(Multimedia Interface Circuit Pack\)](#) alarm.

---

## Demand tests descriptions and error codes

There are no demand tests for MMI-SYNC.

# MODEM-BD (Modem Pool Circuit Pack)

| MO Name in Log | Alarm Level | Initial Command to Run     | Full Name of MO         |
|----------------|-------------|----------------------------|-------------------------|
| MODEM-BD       | MIN<br>WRN  | <i>test board location</i> | Modem Pool circuit pack |

Refer to [XXX-BD \(Common Port Circuit Pack/Media Module\)](#) for circuit pack-level errors.

See [MODEM-PT \(Modem Pool Port\)](#) for related port information.

## MODEM-PT (Modem Pool Port)

| MO Name in Log | Alarm Level | Initial Command to Run    | Full Name of MO |
|----------------|-------------|---------------------------|-----------------|
| MODEM-PT       | MIN         | <i>test port location</i> | Modem Pool Port |

The Modem Pool Port provides an interface for digital and analog data communication devices or ports connected to the PBX. It may be thought of as a PBX data communications “conversion resource” because it converts analog modem signals typically used in the telephone network into digital signals that are compatible with the internal PBX network and vice versa.

There may be a number of these conversion resources available in the PBX, each assigned to an available Modem Pool Group. Only one conversion resource is used per data connection. The PBX software usually adds the conversion resource into a data connection if it determines that it is necessary for the call. Typical connections that include Modem Pool conversion resources include data calls from Analog Line or Central Office Trunk ports to any digital port or Digital Line or Trunk ports to any analog port. An example of a Data Module to Central Office Trunk connection using a Modem Pool conversion resource is shown in [Figure 46: Typical Modem Pool Switched Connection with Integrated Pooled Modem](#). In the case where a local data call originates from an analog port normally used for voice service only and terminates on a digital port, a Data Origination access code must be dialed before the extension number for the Modem Pool conversion resource to be included in the connection.

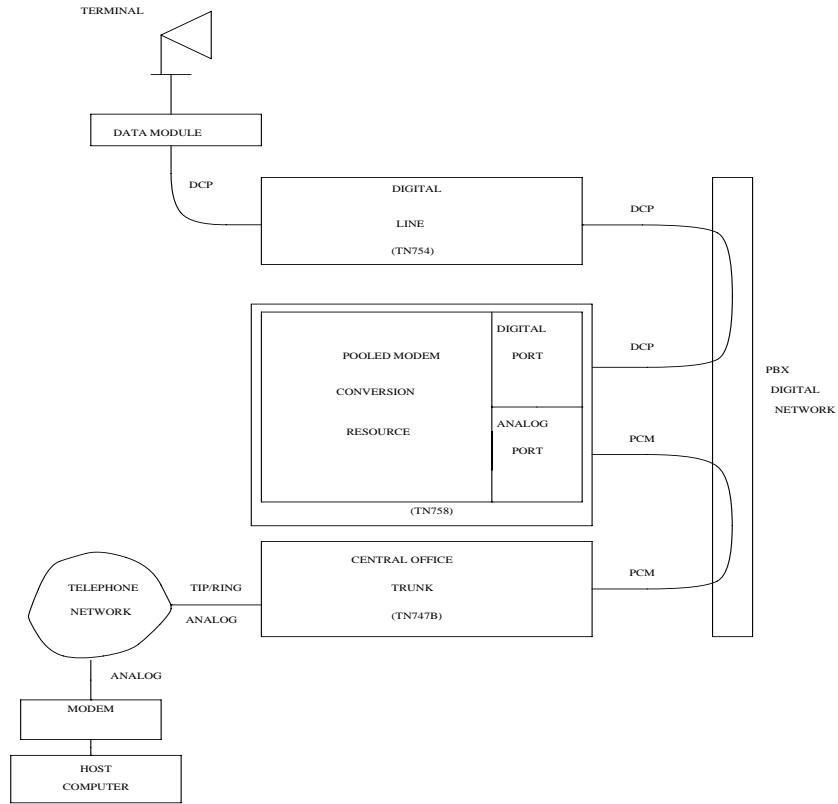

Each Modem Pool conversion resource contains two ports. One of these, an analog port, is connected (via the PBX network) to the analog line or trunk port that is the source of the modem signal. The second port is referred to as the digital port and is connected (again through the PBX network) to the digital line or trunk port associated with the Data Module in the connection. The analog modem signals enter the analog port of the conversion resource in standard Pulse Code Modulation (PCM) format, but are converted into Data Communications Protocol (DCP) format before going to the digital line or trunk in the connection.

---

## Integrated Modem Pools

There are two primary types of Modem Pool conversion resources available: an Integrated Pooled Modem and a Combined Modem Pool. The integrated TN758 Pooled Modem circuit pack contains two independent 300- or 1200-bps conversion resources. Each conversion resource contains two interfaces to the PBX digital network: an analog port and a digital port. The analog port is connected through the PBX network to the analog line or trunk port containing the analog modem signals. The digital port connects through the PBX network to the digital line or trunk port in the call. [Figure 46: Typical Modem Pool Switched Connection with Integrated Pooled Modem](#) on page 668 shows a typical end-to-end connection using a conversion resource on the integrated Pooled Modem circuit pack.

**Figure 46: Typical Modem Pool Switched Connection with Integrated Pooled Modem**

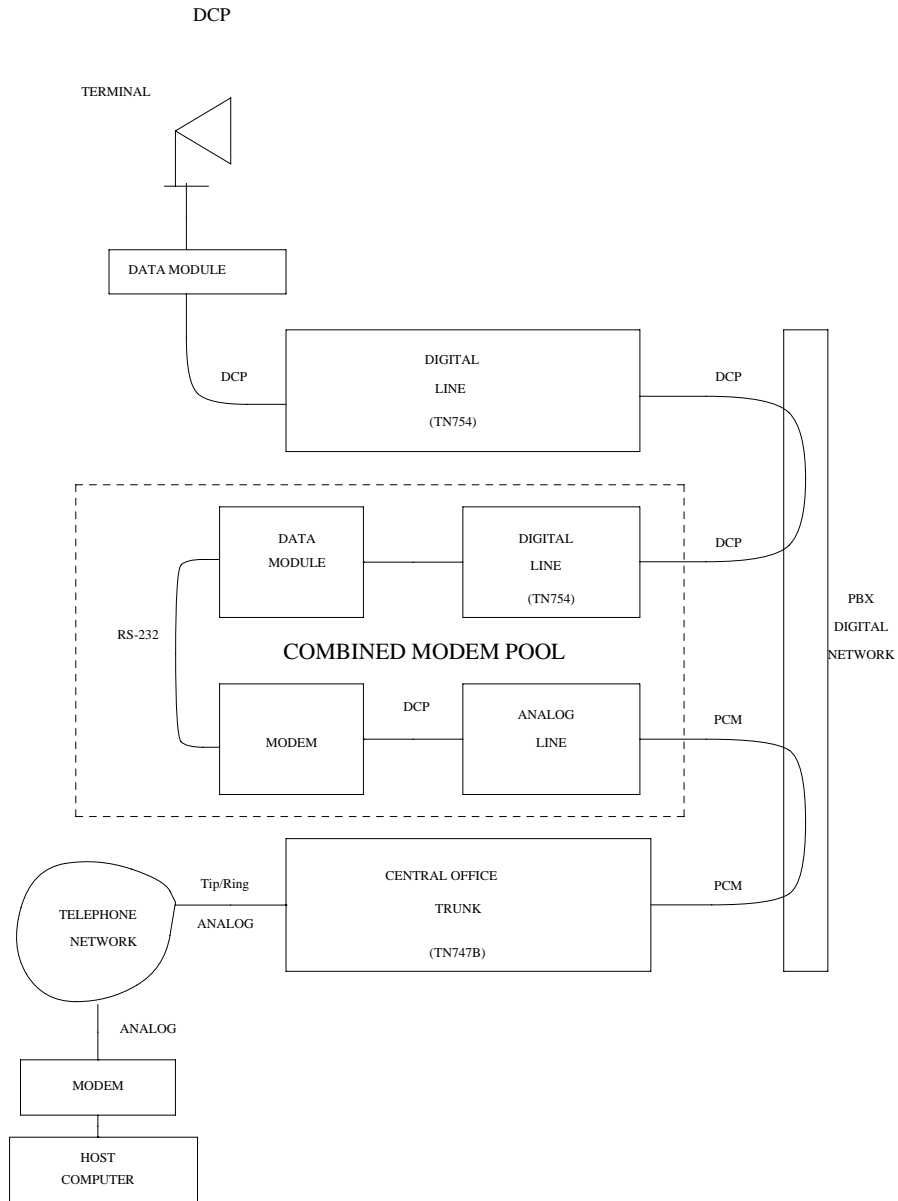

## Combined Modem Pools

The Combined Modem Pool conversion resource is the second type available. The function served by the Combined Modem Pool is similar to that of the integrated Pooled Modem circuit pack, but the physical implementation is much different. It has the advantage of supporting any speed the external modem can support. The integrated Pooled Modem circuit pack can only support 300- or 1200-bps transmission rates. The Combined Modem Pool conversion resource consists of a port on an Analog Line circuit pack, an external modem, a Data Module, and a port on a TN754 Digital Line circuit pack. The tip and ring interface of the Analog Line is connected to the modem, the RS-232C interface of the modem connects to the Data Module, and the DCP interface on the Data Module is connected to the Digital Line port.

The analog modem signals pass through the Analog Line port to the modem. The modem converts these to RS-232C signals which are passed on to the Data Module. The Data Module further converts the signals to the DCP protocol for the Digital Line port which passes the signals on to the PBX network.

Figure 47: Typical Modem Pool Switched Connection with Combined Modem Pool

---

## Troubleshooting Modem-Pool Symptoms

Certain customer-reported troubles may provide important information for troubleshooting Modem Pool problems. For example, if the customer tries to make a data call requiring a Modem Pool conversion resource, and the Modem Pool and Data Module speeds or other options do not match, they may receive a **CHECK OPTIONS** error message on the terminal. In this case, check the Modem Pool administration and Data Module option settings. If the Modem Pool is a Combined type, check also the option settings on the external Modem and Data Module, and cabling and connections between the Digital Line port, Data Module, Analog Line port, and Modem.

---

## Testing Modem Pools

There are three types of commands that can be used to test Modem Pool circuits: `test port`, `test modem-pool #`, and `test board`. The `test port` command is generally the first test to run after the Error Log is evaluated and an entry is found for a Modem Pool port. The `test modem-pool #` command runs the same tests as `test port short` performed on a Modem Pool port. However, `test modem-pool #` can automatically test every port in the Modem Pool group number specified in `#`. The `test board` command performs the same tests as `test port` and `test modem-pool #` plus additional tests for circuits common to the entire circuit pack.

If the Modem Pool port or group being tested with `test modem-pool #` contains Combined Modem Pools, the ports on the associated Analog Line circuit pack and the TN754 Digital Line circuit pack are tested as a group. Note, however, that Combined Modem Pools are not tested and the repair information related to Tests #96, 97, 98, and 99 is not applicable. The Analog port of the Combined Modem port is tested with Analog port tests, and the Digital port of the Combined Modem port is tested with TDMODULE/PDMODULE tests. Therefore, use the repair procedures outlined in the ANL-LINE, ANL-16-L, ANL-NE-L, and TDMODULE/PDMODULE Maintenance documentation when interpreting the results of the execution of `test modem-pool #` on Combined Modem Pools.

---

## Error log entries and recommended actions

Table 193: MODEM-PT Error Log Entries 1 of 2

| Error Type | Aux Data | Associated Test | Alarm Level | On/Off Board | Recommended Action              |
|------------|----------|-----------------|-------------|--------------|---------------------------------|
| 0 (a)      | 0        | Any             | Any         | Any          | <code>test port location</code> |
|            |          |                 |             |              | <i>1 of 2</i>                   |

Table 193: MODEM-PT Error Log Entries 2 of 2

| Error Type | Aux Data | Associated Test                | Alarm Level | On/Off Board | Recommended Action              |
|------------|----------|--------------------------------|-------------|--------------|---------------------------------|
| 18         | 0        | <i>busyout port location</i>   | WRN         | OFF          | <i>release port location</i>    |
| 130 (b)    |          |                                | WRN         | ON           | <i>test port location</i>       |
| 257        |          | Conversion Resource Loop (#98) | MIN         | ON           | <i>test port location r 3</i>   |
| 513        |          | Modem Conference (#97)         | MIN         | ON           | <i>test port location 1 r 3</i> |
| 769        |          | Modem NPE Crosstalk (#96)      | MIN         | ON           | <i>test port location 1 r 3</i> |
|            |          |                                |             |              | <b>2 of 2</b>                   |

## Notes:

- a. **Error Type 0:** run the short test sequence first. If every test passes, run the long test sequence. Refer to each test's description, and follow its procedures.
- b. **Error Type 130:** the circuit pack has been removed or has been insane for more than 21 minutes. To clear the error, reinsert or replace the circuit pack.

---

## Demand test descriptions and error codes

Investigate tests in the order presented. By clearing errors associated with the first test, errors generated from other tests may also be cleared. Click on the link to see the full description of the test, error codes, and recommended actions.

| Order of Investigation                                               | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|----------------------------------------------------------------------|---------------------|--------------------|-------------------|
| <a href="#">Modem Pool NPE Crosstalk Test (#96)</a>                  |                     | X                  | D                 |
| <a href="#">Modem Pool Conference Test (#97)</a>                     |                     | X                  | D                 |
| <a href="#">Modem Pool Conversion Resource Looparound Test (#98)</a> | X                   | X                  | ND                |
| <a href="#">Modem Pool Audit Test (#99)</a>                          | X                   | X                  | ND                |

1. D = Destructive, ND = Nondestructive

### Note:

The tests do not apply to Combined Modem Pool conversion resources. The standard Digital Line and/or Analog Line port tests are run on the ports associated with the Combined Modem Pool. Consult the test descriptions for those MOs when repairing Combined Modem Pool arrangements.

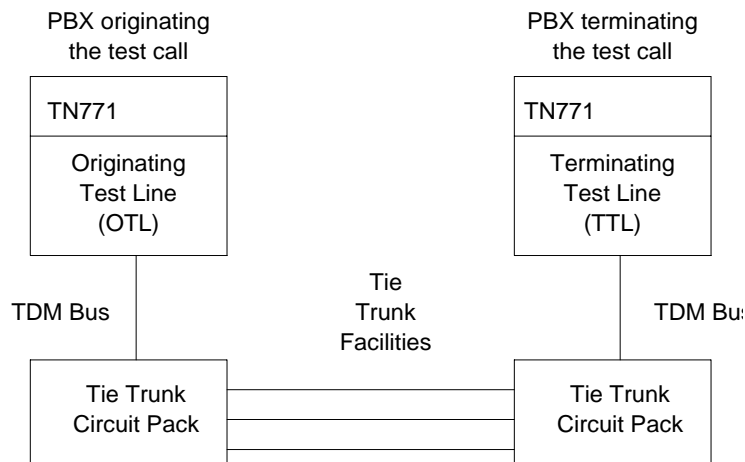

## M/T-ANL (Maintenance/Test Analog Port)

| MO Name in Log | Alarm Level | Initial Command to Run             | Full Name of MO              |
|----------------|-------------|------------------------------------|------------------------------|
| M/T-ANL        | MIN         | <code>test port location 1</code>  | Maintenance/Test analog port |
|                | WRN         | <code>release port location</code> |                              |

The Maintenance/Test analog port is port number 1 on the TN771D Maintenance/ Test circuit pack. This port is used by the Automatic Transmission Measurement System (ATMS) as an Originating Test Line (OTL) or Terminating Test Line (TTL) for test calls over analog trunks. For more details, see [Automatic Transmission Measurement System](#) in *Maintenance Procedures (03-300432)*. [Figure 48](#) shows a typical ATMS configuration.

M/T-ANL maintenance ensures that the analog trunk's testing function is operating correctly. Although an M/T-ANL alarm can reduce service, it will not block service. To accurately measure the performance and health of analog trunks, replace an alarmed TN771D when a new circuit pack is available.

**Figure 48: ATMS Tie Trunk Test Call**

## Error log entries and recommended actions

**Table 194: M/T-ANL Error Log Entries**

| Error Type | Aux Data | Associated Test                      | Alarm Level | On/Off Board | Recommended Action              |
|------------|----------|--------------------------------------|-------------|--------------|---------------------------------|
| 0 (a)      | 0        | Any                                  | Any         | Any          | <i>test port location</i>       |
| 1 (b)      | 41018    |                                      | MIN         | ON           | <i>test port location 1 r 3</i> |
| 18         | 0        | <i>busyout port location</i>         | WRN         | OFF          | <i>release port location</i>    |
| 257        | Any      | GPP NPE Crosstalk Test (#9)          | MIN         | ON           | <i>test port location 1 r 3</i> |
| 513        | Any      | Analog Port Sanity test (#963)       | MIN         | ON           | <i>test port location r 2</i>   |
| 769        | Any      | Analog Port Digital Looparound (#13) | MIN         | ON           | <i>test port location r 3</i>   |
| 3840 (c)   | Any      | Hook State Inquiry test (#566)       |             |              |                                 |
|            |          |                                      |             |              |                                 |

Notes:

- a. **Error Type 0:** run the short test sequence first. If every test passes, run the long test sequence. Refer to each test's description, and follow its procedures. This Error Code appears in the Error Log only if the MTB circuit pack has been removed since the Error Log was last cleared. Verify that the circuit pack has been reinserted.
- b. **Error Type 1:** a hardware failure on the Analog Port circuitry. Replace the Maintenance/Test circuit pack if the command does not resolve the alarm.
- c. **Error Type 3840:** call processing records did not agree with on-board records for the hook state (on-/off-hook) of the Maintenance/Test analog port. This error is not service-affecting and no action is required.

---

## Demand test descriptions and error codes

Investigate tests in the order presented. By clearing errors associated with the first test, errors generated from other tests may also be cleared. Click on the link to see the full description of the test, error codes, and recommended actions.

| Order of Investigation                           | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|--------------------------------------------------|---------------------|--------------------|-------------------|
| <a href="#">Analog Port Sanity Test (#963)</a>   | X                   | X                  | ND                |
| <a href="#">Local Loop Test (#13)</a>            | X                   | X                  | ND                |

| <a href="#">Hook State Inquiry Test (#566)</a>   | X                   | X                  | ND                |
| <a href="#">Clear Error Counters Test (#270)</a> |                     | X                  | ND                |

1. D = Destructive, ND = Nondestructive

## M/T-BD (Maintenance/Test Circuit Pack)

| MO Name in Log | Alarm Level | Initial Command to Run                | Full Name of MO               |
|----------------|-------------|---------------------------------------|-------------------------------|
| M/T-BD         | MIN         | <code>test board location long</code> | Maintenance/Test circuit pack |
|                | WRN         | <code>release board location</code>   |                               |

The Maintenance/Test circuit pack (TN771D) supports packet bus fault detection and bus reconfiguration for the port network where it is installed. The circuit pack also provides Analog Trunk testing, and data loopback testing of DCP Mode 2 endpoints and Digital (ISDN) Trunk facilities via the TDM bus.

Port 1 of the Maintenance/Test board is the Analog Test port which provides the Analog Trunk testing function for Automatic Transmission Measurement System (ATMS). ATMS is a feature in which calls are made from a device called an Originating Test Line (OTL) over a specific trunk to a device called a Terminating Test Line (TTL). The OTL and TTL can then send tones over the trunk under test and determine the quality of the connection. Ports 2 and 3 are the digital ports which provide the digital (ISDN) trunk-testing functions. Port 4 is the packet port which provides the packet bus maintenance function. For more information, see *Maintenance Procedures (03-300432)*.

See [XXX-BD \(Common Port Circuit Pack/Media Module\)](#) for circuit pack-level errors. See also related maintenance/test information for analog, digital, and packet bus ports:

- 1 [MG-ANA \(Analog Media Module\)](#)
- 1 [M/T-DIG \(Maintenance/Test Digital Port\)](#)
- 1 [M/T-PKT \(Maintenance/Test Packet Bus Port\)](#)

Every port except the analog port (Port 1) of the Maintenance/Test board is automatically administered when the circuit pack is inserted into the system and automatically removed when the circuit pack is unplugged from the system. The Analog port however, is administered using the **station** screen with the type "105TL" for an OTL or a TTL. This port remains administered even after the circuit pack is physically removed from the system. Care should be taken to remove the OTL or the TTL before unplugging the circuit pack.

## Error log entries and recommended actions

**Table 195: M/T-BD Error Log Entries**

| Error Type | Aux Data     | Associated Test                       | Alarm Level <sup>1</sup> | On/Off Board | Recommended Action             |
|------------|--------------|---------------------------------------|--------------------------|--------------|--------------------------------|
| 0 (a)      | 0            | Any                                   | Any                      | Any          | <i>test port location</i>      |
| 1 (b)      | 0            | SAKI Sanity test (#53)                | MIN                      | ON           |                                |
| 18 (c)     | 0            | <i>busyout board location</i>         | WRN                      | OFF          | <i>release board location</i>  |
| 36 (d)     | 0            |                                       |                          |              |                                |
| 217 (f)    |              |                                       | WRN                      | ON           |                                |
| 257 (e)    | 0            | Control Channel Looparound Test (#52) | MIN                      | ON           | <i>test board location r 3</i> |
| 267 (f)    |              |                                       | WRN                      | ON           |                                |
| 513 (g)    | 4352 to 4357 |                                       |                          |              |                                |
| 769 (h)    | 4358         |                                       |                          |              |                                |
| 1025 (i)   | 4363         | NPE Audit Test (#50)                  |                          |              | <i>test board location 1</i>   |
| 1538 (j)   | 0            |                                       | MIN                      | ON           |                                |
| 3840 (k)   | 4096 to 4101 |                                       |                          |              |                                |
| 3999 (l)   | Any          | None                                  |                          |              |                                |

1. Major or Minor alarms on this MO may have been downgraded to Warning based on the values in **set options**.

### Notes:

- a. **Error Type 0:** run the short test sequence first. If every test passes, run the long test sequence. Refer to each test's description, and follow its procedures.
- b. **Error Type 1:** the circuit pack has stopped functioning. Reset the circuit pack using *busyout board location*, *reset board location*, and *release board location*. If the SAKI Sanity test (#53) passes, the on-board circuitry is healthy. If the SAKI Sanity test (#53) fails, replace the circuit pack.

- c. **Error Type 18:** the circuit pack has been busied out by the command `busyout board location`. Execute `release board location`.
- d. **Error Type 36:** a port processor on the circuit pack failed to initialize. Reset the circuit pack using `busyout board location`, `reset board location`, and `release board location`. If the problem does not go away, replace the circuit pack.
- e. **Error Type 257:** a Control Channel Protocol error has occurred. This may be due to the circuit pack detecting an on-board hardware failure. Execute `busyout board location` and `reset board location` to reset the circuit pack. Any such problem will be detected during initialization, because the circuit pack locks up and appears insane to the system.
- f. **Error Type 217, 267:** an extra TN771D circuit pack has been inserted into the port network.
- g. **Error Type 513:** an on-board hardware failure has been detected by the circuit pack. Enter the `busyout board location`, `reset board location`, and `release board location` commands to reset the circuit pack. If the SAKI Sanity test (#53) passes, the circuitry is healthy. If not, replace the circuit pack.
- h. **Error Type 769:** program logic error; no action is required. This error may lead to errors of other types being reported against this circuit pack.
- i. **Error Type 1025:** the circuit pack cannot update NPE memory and read it back. This Error Type can be ignored, but might lead to errors of other types being reported against this circuit pack.
- j. **Error Type 1538:** excessive number of messages have been received from the Maintenance/Test circuit pack. This may be due to a hardware problem on the circuit pack. The switch takes the board out of service and periodically puts it back into service to see if the problem has disappeared. If the problem persists, replace the circuit pack.
- k. **Error Type 3840:** the circuit pack received a bad control channel message from the switch. This error is not service affecting and no action is required.
- l. **Error Type 3999:** the circuit pack sent a large number of control channel messages to the switch within a short period of time. If Error Type 1538 is also present, then the circuit pack was taken out-of-service due to hyperactivity. If Error Type 1538 is absent, then the circuit pack was not taken out-of-service, but it has generated 50% of the messages necessary to be considered hyperactive. This may be completely normal during heavy traffic periods. However, if this Error Type is logged when the circuit pack is being lightly used, it may indicate a problem with the circuit pack or the equipment attached to it.

---

## Demand test descriptions and error codes

Investigate tests in the order presented. By clearing errors associated with the first test, errors generated from other tests may also be cleared. Click on the link to see the full description of the test, error codes, and recommended actions.

| Order of Investigation                                | Short Test Sequence | Long Test Sequence | D/ND           |
|-------------------------------------------------------|---------------------|--------------------|----------------|
| <a href="#">Control Channel Looparound Test (#52)</a> | X                   | X                  | Nondestructive |
| <a href="#">NPE Audit Test (#50)</a>                  |                     | X                  | Nondestructive |

## M/T-DIG (Maintenance/Test Digital Port)

| MO Name in Log | Alarm Level | Initial Command to Run             | Full Name of MO               |
|----------------|-------------|------------------------------------|-------------------------------|
| M/T-DIG        | MIN         | <code>test port location 1</code>  | Maintenance/Test Digital Port |
|                | WRN         | <code>release port location</code> |                               |

The Maintenance/Test digital port is a port on the TN771D circuit pack. Ports 2 and 3 are digital ports. The Maintenance/Test digital port provides the ability to perform digital (i.e., ISDN-PRI) trunk testing via the TDM bus. For an ISDN-PRI test call, connections are set up in the system as shown in [Figure 49: ISDN-PRI Outgoing Test Call](#).

When the Maintenance/Test digital port is participating in an ISDN-PRI test call, the port sends a stream of pseudo-random data along the connected B-Channel. The far end loops back this data, and the Maintenance/Test digital port compares the data to that which was sent. Errors are recorded on a bit and block basis. Refer to [ISDN-TRK \(DS1 ISDN Trunk\)](#) for more information about ISDN-PRI test calls.

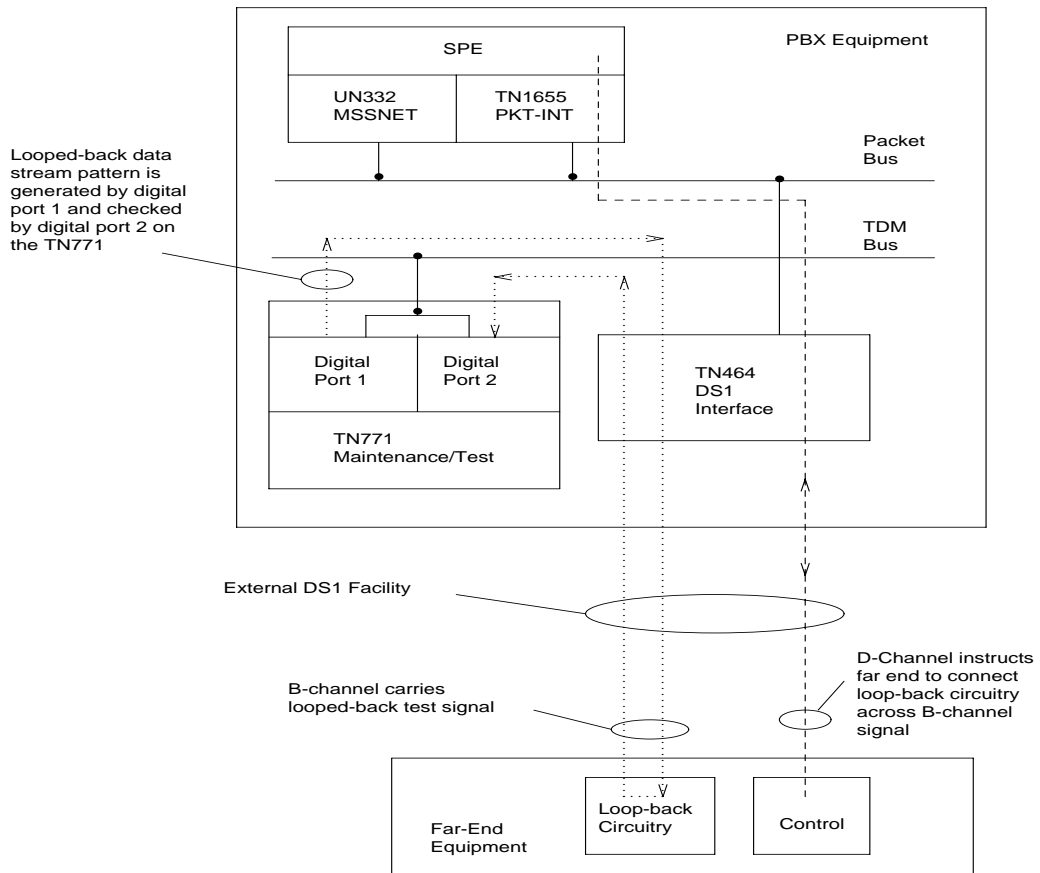

The Maintenance/Test digital port maintenance ensures that the digital trunk testing function is operating correctly. The Maintenance/Test digital port is alarmed if maintenance determines that the digital port is operating incorrectly.

**Note:**

An alarm on the Maintenance/Test digital port reduces service, but does not block it since the ISDN-TRK has other means to determine the health of the ISDN-PRI trunk facility. However, to accurately measure the error performance and to ensure accuracy of the health of the ISDN-PRI trunk, the Maintenance/Test circuit pack should be replaced when a new circuit pack is available.

Figure 49: ISDN-PRI Outgoing Test Call

## Error log entries and recommended actions

Table 196: M/T-DIG Error Log Entries 1 of 2

| Error Type | Aux Data | Associated Test       | Alarm Level | On/Off Board | Recommended Action       |
|------------|----------|-----------------------|-------------|--------------|--------------------------|
| 0 (a)      | 0        | Any                   | Any         | Any          | test port location       |
| 1 (b)      | 41018    |                       | MIN         | ON           | test port location 1 r 3 |

|------------|----------|------------------------------------|-------------|--------------|---------------------------------------|
| 257 (d)    | Any      | GPP NPE Crosstalk Test (#9)        | MIN         | ON           | <code>test port location 1 r 3</code> |
| 513 (e)    | Any      | Digital Port Sanity test (#565)    | MIN         | ON           | <code>test port location r 2</code>   |
| 769 (f)    | Any      | Digital Port Looparound Test (#13) | MIN         | ON           | <code>test port location r 3</code>   |
| 3840 (g)   | Any      | Hook State Inquiry test (#566)     |             |              |                                       |
|            |          |                                    |             |              | <b>2 of 2</b>                         |

Notes:

- a. **Error Type 0:** run the short test sequence first. If every test passes, run the long test sequence. Refer to each test's description, and follow its procedures.
- b. **Error Type 1:** there was a hardware failure on a digital port's circuitry. Replace the Maintenance/Test circuit pack if the alarm is not resolved by the command above.
- c. **Error Type 18:** the port was busied out by `busyout port location`. Release the port using `release port location`.
- d. **Error Type 257:** the Maintenance/Test digital port is talking on more than just its assigned time slot. Replace the Maintenance/Test circuit pack.
- e. **Error Type 513:** the Maintenance/Test digital port has failed its self-test. Because the Digital Port Sanity test runs only on port 2, but tests both ports 2 and 3, both ports are alarmed when the test fails. The command indicates to test port 2, even if the error is logged against port 3.
- f. **Error Type 769:** the Maintenance/Test digital port was unable to successfully loop data from a tone generator to a tone detector.
- g. **Error Type 3840:** call processing records do not agree with on-board records for the hook state (on-/off-hook) of the Maintenance/Test digital port. This error is not service-affecting and no action is required.

---

## Demand test descriptions and error codes

Investigate tests in the order presented. By clearing errors associated with the first test, errors generated from other tests may also be cleared. Click on the link to see the full description of the test, error codes, and recommended actions.

| Order of Investigation                           | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|--------------------------------------------------|---------------------|--------------------|-------------------|
| <a href="#">Digital Port Sanity Test (#565)</a>  | X                   | X                  | ND                |
| <a href="#">Local Loop Test (#13)</a>            | X                   | X                  | ND                |
| <a href="#">GPP NPE Crosstalk Test (#9)</a>      |                     | X                  | ND                |

| <a href="#">Clear Error Counters Test (#270)</a> |                     | X                  | ND                |

1. D = Destructive, ND = Nondestructive

## M/T-PKT (Maintenance/Test Packet Bus Port)

| MO Name in Log | Alarm Level | Initial Command to Run         | Full Name of MO                  |
|----------------|-------------|--------------------------------|----------------------------------|
| M/T-PKT        | MIN         | <i>test port location long</i> | Maintenance/Test Packet Bus port |
|                | WRN         | <i>release port location</i>   |                                  |

The Maintenance/Test packet bus port (M/T-PKT) is Port #4 on the TN771D Maintenance/Test circuit pack. The packet bus port provides the following packet bus maintenance functions:

1 Packet bus fault detection

The ability to detect faults (for example, shorts, open leads) on the packet bus autonomously (i.e., without Communication Manager involvement).

1 Packet bus re-configuration

The ability to swap faulty leads with spare leads autonomously so that the packet bus remains operational. This is accomplished by sending a message to every circuit pack using the packet bus (for example, TN556 ISDN-BRI), telling it which spare leads to use on the bus.

M/T-PKT maintenance ensures that these maintenance functions are operating correctly. The Maintenance/Test packet bus port is alarmed if maintenance determines that the port's maintenance functions are operating incorrectly.

When M/T-PKT maintenance determines that the packet bus port is defective, the packet bus fault-detection and re-configuration functions provided by the port will be turned off.

M/T-PKT maintenance interacts with packet bus maintenance. Therefore, there may be alarms on the packet bus when there is a fault on the M/T-PKT. For further information, refer to the PKT-BUS MO's section.

---

## Error log entries and recommended actions

**Table 197: M/T-PKT Error Log Entries 1 of 2**

| Error Type            | Aux Data | Associated Test | Alarm Level | On/Off Board | Recommended Action              |
|-----------------------|----------|-----------------|-------------|--------------|---------------------------------|
| 0 <a href="#">(a)</a> | 0        | Any             | Any         | Any          | <i>test port location</i>       |
| 1 <a href="#">(b)</a> | 41018    |                 | MIN         | ON           | <i>test port location 1 r 3</i> |
|                       |          |                 |             |              | <b>1 of 2</b>                   |

Table 197: M/T-PKT Error Log Entries 2 of 2

| Error Type | Aux Data | Associated Test                       | Alarm Level | On/Off Board | Recommended Action            |
|------------|----------|---------------------------------------|-------------|--------------|-------------------------------|
| 18 (c)     | 0        | <i>busyout port location</i>          | WRN         | OFF          | <i>release port location</i>  |
| 257 (d)    | Any      |                                       | MIN         | ON           |                               |
| 513 (e)    | Any      | Packet Bus Port Health Inquiry (#567) | MIN         | ON           | <i>test port location r 3</i> |
|            |          |                                       |             |              | <b>2 of 2</b>                 |

## Notes:

- a. **Error Type 0:** run the short test sequence first. If every test passes, run the long test sequence. Refer to each test's description, and follow its procedures.
- b. **Error Type 1:** hardware failure with the port circuitry that provides the packet bus maintenance functions. Replace the Maintenance/Test circuit pack if the alarm is not resolved by the test command above.
- c. **Error Type 18:** the port has been busied out by *busyout port location*. Release the port with *release port location*.
- d. **Error Type 257:** the Maintenance/Test packet bus port reconfigured the packet bus by swapping a bad lead to a spare. Note that this error is sent up whenever the Maintenance/Test packet bus port is initialized since the packet bus port reconfigures the packet bus to whatever state it determines the packet bus is in. This will occur if the circuit pack is inserted, if the system is restarted, or if the port is released from a busyout state. Therefore, it is normal for this error to be present in the error log.

If the M/T-PKT reconfigures the packet bus 6 times within 15 minutes, a Minor alarm is raised indicating that either:

- 1 Packet bus maintenance functions are not operating correctly
- 1 Many changes are taking place on the packet bus (insertions or removals of circuit packs)

If the system has been in a stable state for more than 15 minutes, try the following procedure:

1. Reset the Maintenance/Test circuit pack from a SAT session as follows:
  - a. Enter *busyout board location*.
  - b. Enter *reset board location*.
  - c. Enter *release board location*.
2. Wait 15 minutes.

3. If the error recurs, replace the Maintenance/Test circuit pack.

When this alarm is active, the amber LED will be in one of three states:

1. An unlit amber LED indicates no activity on the Maintenance/Test circuit pack. You can replace the Maintenance/Test circuit pack.
  1. If there is an indication of an uncorrectable fault on the packet bus, the amber LED will be blinking at a rate of 1 Hz. It is OK to replace the Maintenance/Test circuit pack. Ignore the packet bus error indication, since the Maintenance/Test circuit pack has been determined to be defective.
  1. If there is other activity on the Maintenance/Test circuit pack (i.e., ISDN test call), or if there is an indication of a correctable fault on the packet bus, the amber LED will be on steady. If there is an ISDN test call in progress, it must be halted using `clear isdnpri-testcall grp#/mem#` prior to replacing the circuit pack. Ignore the packet bus error indication, since the Maintenance/Test circuit pack has been determined to be defective.
- e. **Error Type 513:** the Packet Bus Port Health Inquiry test failed. Either the packet bus port has reported a self-test failure, or Communication Manager can communicate with the Maintenance/Test circuit pack but not with the Maintenance/Test circuit pack packet bus port. Refer to the description of the [Packet Bus Port Health Inquiry Test \(#567\)](#), and follow the instructions indicated for the failure code that matches the **Aux Data** field.

---

## Demand test descriptions and error codes

Investigate tests in the order presented. By clearing errors associated with the first test, errors generated from other tests may also be cleared. Click on the link to see the full description of the test, error codes, and recommended actions.

| Order of Investigation                                     | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|------------------------------------------------------------|---------------------|--------------------|-------------------|
| <a href="#">Packet Bus Port Health Inquiry Test (#567)</a> | X                   | X                  | ND                |
| <a href="#">Clear Error Counters Test (#270)</a>           |                     | X                  | ND                |

1. D = Destructive, ND = Nondestructive

## NO-LIC (No License)

| MO Name in Log | Alarm Level | Initial Command to Run | Full Name of MO |
|----------------|-------------|------------------------|-----------------|
| NO-LIC         | MAJ         | None                   | NO License      |

**Note:**

The NO-LIC MO is non-traditional in that there are no associated tests or commands that can be executed. There are no demand tests to run.

---

## How systems go into No-License mode

The NO-LIC MO works with the LIC-ERR MO to find any errors/violations associated with the License File. Once a License File error occurs, LIC-ERR logs the error, raises an alarm, and generates the following SAT login message:

*“System Administration Will Be Blocked in Approximately XXX hours.  
Contact Your Service Representative.”*

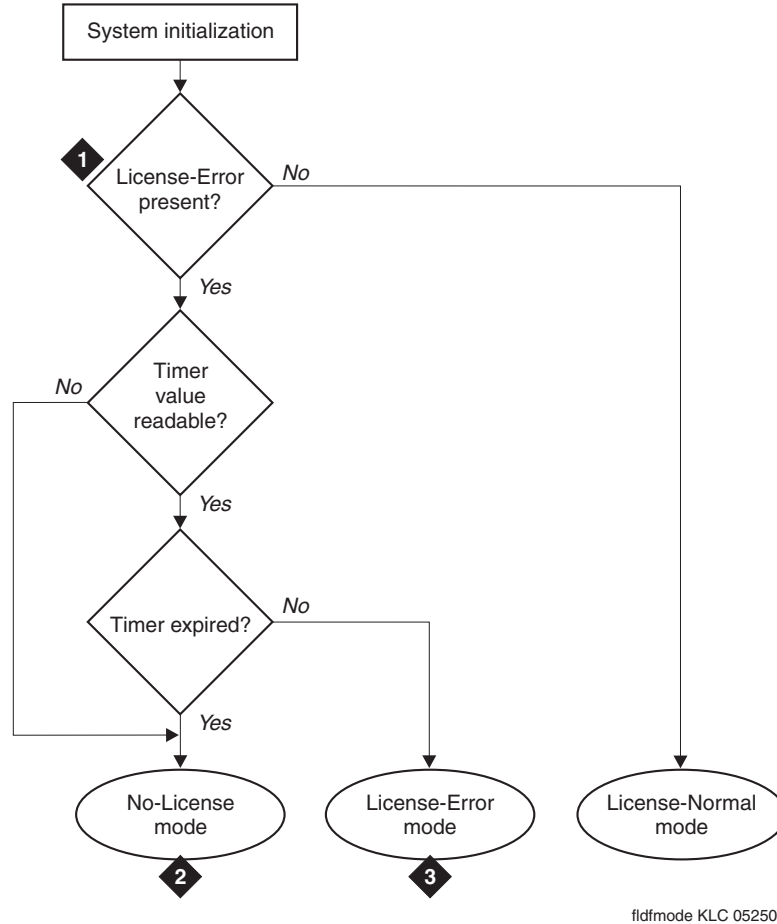

Entry into License-Error mode starts a timer that, when expired, causes the system to enter No-License mode (see [Figure 50: License mode algorithm](#)). When Communication Manager enters No-License mode, the following SAT warning message displays:

*“System Administration Is Blocked.  
Contact Your Service Representative Immediately.”*

The system also responds with these conditions:

- 1 “LICENSE ERROR” displays on all stations and consoles when they go off-hook, but disappears when the first digit is pressed. This display message does not interfere with the normal use of any station or console.
- 1 All terminal-login sessions are terminated.
- 1 Any subsequent terminal-login sessions are limited to
  - Maintenance commands.
  - License File installation command.

**Figure 50: License mode algorithm**

**Figure notes:**

1. See [Troubleshooting License File errors](#).
2. See [How systems go into No-License mode](#).
3. See [Troubleshooting License File errors](#).

The License File feature is loaded onto a switch during initialization of the switch software, restore of translations, and periodically thereafter. After initialization, a query is made to a software module called the license server. This module reads the License File, compares a serial number in the License File to a serial number in hardware, and compares the software version in the license with the running software version. If a match occurs, the license server delivers a new feature mask, an information set that controls which features are enabled or not on the **Customer Options** and **Special Applications** screens.

## Error log entries and recommended actions

| Error Type | Aux Data | Associated Test | Alarm Level | On/Off Board | Recommended Action <sup>1</sup> |
|------------|----------|-----------------|-------------|--------------|---------------------------------|
| 1 (a)      |          |                 | MAJ         | OFF          |                                 |
| 513 (b)    |          |                 | MAJ         | OFF          |                                 |
| 769 (c)    |          |                 | MAJ         | OFF          |                                 |
| 1537 (d)   |          |                 | MAJ         | OFF          |                                 |
| 1793 (e)   |          |                 | MAJ         | OFF          |                                 |
| 2305 (f)   |          |                 | MAJ         | OFF          |                                 |
| 2561 (g)   |          |                 | MAJ         | OFF          |                                 |

1. These errors are cleared by installing a valid License File that matches the hardware ID(s).

### Notes:

a. **Error Type 1:** There is a serial number mismatch caused by:

- 1 **S8700 | S8710 | S8720 | S8500:** reference IPSI not responding.
- 1 **S8300:** motherboard not responding.
- 1 Expiration of the timer.

The system enters No-License mode.

b. **Error Type 513:** the license has expired and:

- 1 A License Error failure has occurred.
- 1 The timer has expired.
- 1 The system enters No-License mode.

c. **Error Type 769:** the system is in the Feature Usage Exceeds Limits mode, and a License Error failure has occurred. System feature use has exceeded limits, and the timer has expired. The system enters No-License mode.

d. **Error Type 1537:** the License File is missing or corrupted. The system enters No-License mode.

e. **Error Type 1793:** a Software Version Mismatch has occurred. The system enters No-License mode.

f. **Error Type 2305:** the Offer Category of the License does not match the Offer Category in translations. The system enters No-License mode.

g. **Error Type 2561**: during the last attempted License File audit, the license server did not respond in time.

---

## **Demand tests descriptions and error codes**

There are no demand tests for NO-LIC.

## NR-CONN (Network-Region Connect)

| MO Name in Log | Alarm Level | Initial Command to Run                     | Full Name of MO        |
|----------------|-------------|--------------------------------------------|------------------------|
| NR-CONN        | MIN<br>WRN  | <code>test failed-ip-network-region</code> | Network-Region Connect |

A network region is a logical grouping of IP endpoints (including IP stations, IP trunks, and media gateways) sharing the same transmission characteristics and/or VoIP and signaling resources, such as a Media Processor board or a C-LAN. The Network-Region Connect (NR-CONN) MO monitors VoIP connectivity between network regions and raises a:

- 1 Warning alarm for a single failure.

This alarm is in response to one failed background ping test between IP endpoints in separate network regions. This test is part of the background [Network Region Interconnectivity Test \(#1417\)](#).

- 1 Minor alarm for multiple failures.

Once a single failure is detected, Test #1417 is re-executed between different IP endpoints in the same pair of network regions. If the test still fails between these network regions:

- Maintenance software marks the connectivity between them as “failed.”
- Communication Manager denies every attempted call between them.

As a background operation during each 2-minute interval, Test #1417 checks the translated connections between 50 pairs of network regions until every translated connection has been tested, and then repeats. (The Communication Manager translation table’s maximum capacity for network-region connections is 31,250. Testing every possible connection would require 625 2-minute test intervals during about 21 hours.)

---

## Repair strategies

- 1 Use `display failed-ip-network-region` to display pairs of network regions with failed connectivity. In descending order of severity, this command lists up to 100 network regions with the most severely broken connectivity.
- 1 Use `status ip-network-region` to see the status of connections from a particular network region.
- 1 As an on-demand operation, `test failed-ip-network-region` retests every network-region connection marked as “failed.” Those connections that:
  - Pass are returned to service.
  - Fail are remarked as “failed” and remain on the list of bad connections.

---

## Error log entries and recommended actions

**Table 198: NR-CONN Error Log Entries**

| Error Type | Aux Data | Associated Test                          | Alarm Level | On/Off Board | Recommended Action |
|------------|----------|------------------------------------------|-------------|--------------|--------------------|
| 1(a)       | 0        | Network Region Connectivity Test (#1417) | MIN         | ON           |                    |

Note:

a. **Error Type 1:** one or more network-region connections have failed.

1. Enter `display failed-ip-network-region` to verify that connections between pairs of network regions are failing.
2. If so, enter `test failed-ip-network-region` to retest these paths.
3. For each affected network region, check the error log for failures to related MOs, such as:
  - IPMEDPRO (IP Media Processor Circuit Pack)
  - MEDPRO (Media Processor MAPD Circuit Pack)
  - CLAN-BD (Control LAN Circuit Pack)
  - DIG-IP-S (Digital IP Station)
  - RDIG-STA (Remote Digital Station)and resolve any problems.
4. Enter `test failed-ip-network-region` to retest these paths.
5. If errors persist, escalate.

---

## Demand test description and error codes

| Order of Investigation                                        | Short Test Sequence | Long Test Sequence | D/ND           |
|---------------------------------------------------------------|---------------------|--------------------|----------------|
| <a href="#">Network Region Interconnectivity Test (#1417)</a> |                     | X                  | Nondestructive |

## NR-REG (Network Region Registrations)

| MO Name in Log | Alarm Level | Initial Command to Run                       | Full Name of MO              |
|----------------|-------------|----------------------------------------------|------------------------------|
| NR-REG         | MIN         | none                                         | Network Region Registrations |
|                | WRN         | <b>enable nr-registration network-region</b> |                              |

The NR-REG maintenance object generates alarms when:

- 1 there has been hyperactive registration of gateways within a network region
- 1 registration from media gateways and IP phones is being denied because the **disable nr-registration network-region** command was executed.

It is assumed that a Survivable Remote Server is provided for the network region and that the gateways and IP phones will register with the Survivable Remote Server based on the primary search list for gateways and the alternate gatekeeper list for IP phones.

NR-REG alarms will only be generated if hyperactive link bounce detection is enabled on the **system-parameters ip-options** screen. Registration will be denied only if the **disable nr-registration network-region** command is entered from the SAT.

The hyperactive NR-REG alarms and the associated **disable/enable nr-registration network-region** commands should only be used for situations where IP network problems cause media gateways and IP phones to repeatedly register and unregister to a server at a rate that is too fast for the normal link bounce strategy to cause the gateways and phones to fail over to a Survivable Remote Server.

The system detects hyperactivity by monitoring the number of link down failures reported to the MED-GTWY maintenance object. When enough link down failures are detected within the administered time frame, an alarm is raised against the offending media gateway. Using this data, a percentage of hyperactive media gateways is calculated and checked against the administered system-wide limit. If the limit is exceeded, a minor alarm is generated for the network region. The system does not try to recover from hyperactivity. It only generates an alarm.

If a certain period of time passes without any additional link down events, the hyperactivity alarm is cleared. The alarm is resolved if less than 50% of the media gateways required to raise an alarm are out of hyperactive mode.

---

## Error log entries and recommended actions

Table 199: NR-REG Error Log Entries

| Error Type | Aux Data | Associated Test | Alarm Level | On/Off Board | Recommended Action                                 |
|------------|----------|-----------------|-------------|--------------|----------------------------------------------------|
| 1 (a)      |          |                 | MIN         | OFF          |                                                    |
| 257 (b)    |          |                 | WRN         | OFF          | <code>enable nr-registration network-region</code> |

Notes:

- a. **Error Type 1:** The percentage of hyperactive media-gateways in a network region exceeds the administered percentage.
  1. Enter `disable nr-registration network-region` so that gateways and IP phones in the specified network region will register to a Survivable Remote Server. The registration of the IP network endpoints to a server is being disabled, not the IP network region itself. The use of this command is a temporary recovery action, not a corrective action.
  2. After the network problem has been corrected, enter `enable nr-registration network-region` to enable registration of the IP network endpoints to a server. This will allow them to re-register with the main server depending upon the administered **Recovery Rule** specified on the `change media-gateway` form.
- b. **Error Type 257:** Registrations for the network region are currently disabled. Enter `enable nr-registration network-region` to enable registration of the ip-network endpoints to a server.

---

## Demand tests descriptions and error codes

There are no demand tests for NR-REG.

## OPS-LINE (DS1 Off-Premises Station Line)

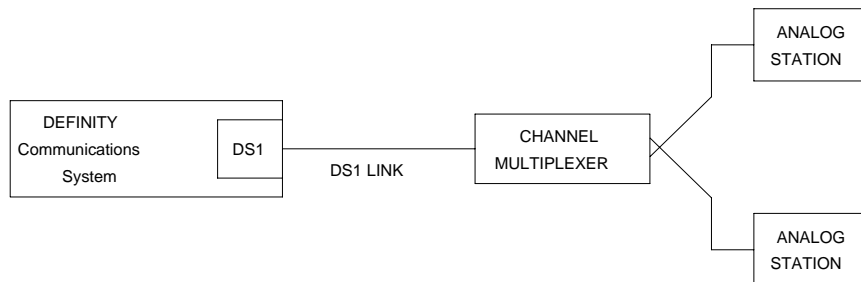

| MO Name in Log | Alarm Level | Initial Command to Run                | Full Name of MO |
|----------------|-------------|---------------------------------------|-----------------|
| OPS-LINE       | MIN         | <code>test station extension 1</code> | DS1 OPS Line    |
|                | WRN         | <code>test station extension</code>   |                 |

An analog Off-Premises Station (OPS) can be connected to the system through a DS1 link. A TN767 DS1 Interface circuit pack or a TN464 UDS1 Interface circuit pack can support up to 24 DS1 OPS lines. Since the DS1 OPS is an analog telephone set, a channel multiplexer is necessary as the remote DS1 endpoint converts the digital signal of a DS1 port to the OPS Line and vice versa.

The DS1 OPS Line Maintenance provides a strategy to maintain an OPS Line via a trunk port of the TN767 DS1 Interface circuit pack or the TN464 UDS1 Interface circuit pack. (Throughout this section, the term DS1 Interface can apply to either of these circuit packs.) The strategy covers initialization tests, periodic tests, scheduled tests, demand tests, and alarm resolution and escalation. Two service states are specified in a DS1 OPS Line maintenance. They are: *out-of-service*, in which the line is in a deactivated state and cannot be used for either incoming or outgoing calls; or *in-service*, in which the line is in an activated state and can be used for both incoming and outgoing calls. If the DS1 Interface circuit pack is out-of-service, then every line on the DS1 Interface circuit pack is put into the out-of-service state, and a Warning alarm is raised.

For maintenance of the remote DS1 endpoint (for example, a Channel Division Multiplexer or D4 Channel Bank), refer to the vendor's maintenance documentation for details.

**Figure 51: DS1 OPS Line Interactions**

## Error log entries and recommended actions

Table 200: OPS-LINE Error Log Entries

| Error Type | Aux Data | Associated Test                  | Alarm Level | On/Off Board | Recommended Action                  |
|------------|----------|----------------------------------|-------------|--------------|-------------------------------------|
| 0 (a)      | 0        | Any                              | Any         | Any          | <code>test station ext</code>       |
| 15 (b)     | Any      | Port Audit and Update Test (#36) |             |              |                                     |
| 18 (c)     | 0        | <code>busyout station ext</code> | WRN         | OFF          | <code>release station ext</code>    |
| 130 (d)    |          |                                  | WRN         | ON           | <code>test station ext</code>       |
| 1281       |          | Conference Circuit Test (#7)     | MIN         | ON           | <code>test station ext l r 4</code> |
| 1537       |          | NPE Crosstalk Test (#6)          | MIN         | ON           | <code>test station ext l r 3</code> |
| 1793 (e)   |          |                                  |             |              | <code>test board location 1</code>  |

Notes:

- a. **Error Type 0:** run the short test sequence first. If every test passes, run the long test sequence. Refer to each test's description, and follow its procedures.
- b. **Error Type 15:** software audit error which does not indicate a hardware malfunction. Run the short test sequence and investigate associated errors (if any).
- c. **Error Type 18:** the DS1 OPS Line was busied out by `busyout station ext`. No calls can be made on this line. Release the line with `release station ext`.
- d. **Error Type 130:** the circuit pack was removed or was insane for more than 11 minutes. To clear the error, reinsert or replace the circuit pack.
- e. **Error Type 1793** there is a problem with the DS1 Interface circuit pack. Because there is no error against the OPS-LINE port, no alarm is raised against the OPS-LINE port. However, there should be errors logged against the DS1 Interface circuit pack. Look for DS1-BD/ UDS1-BD errors in the Error Log, and follow the procedures in [DS1-BD \(DS1 Interface Circuit Pack\)](#).

---

## Demand test descriptions and error codes

Investigate tests in the order presented. By clearing errors associated with the first test, errors generated from other tests may also be cleared. Click on the link to see the full description of the test, error codes, and recommended actions.

| Order of Investigation                                 | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|--------------------------------------------------------|---------------------|--------------------|-------------------|
| <a href="#">NPE Crosstalk Test (#6)</a>                |                     | X                  | ND                |
| <a href="#">Conference Circuit Test (#7)</a>           |                     | X                  | ND                |
| <a href="#">DS1 OPS Switchhook Inquiry Test (#312)</a> | X                   | X                  | ND                |
| <a href="#">Port Audit And Update Test (#36)</a>       | X                   | X                  | ND                |

1. D = Destructive; ND = Nondestructive

## PDMODULE (Processor Data Module)

| MO Name in Log        | Alarm Level | Initial Command to Run               | Full Name of MO       |
|-----------------------|-------------|--------------------------------------|-----------------------|
| PDMODULE <sup>1</sup> | MIN         | <code>test port location long</code> | Processor Data Module |
|                       | WRN         | <code>test port location</code>      |                       |
| TDMODULE <sup>2</sup> | MIN         | <code>test port location long</code> | Trunk Data Module     |
|                       | WRN         | <code>test port location</code>      |                       |

1. Digital Terminal Data Modules (DTDM), and Data Adaptors (DA) in linked mode are considered part of the Digital Line MO. See the DIG-LINE section for maintenance of these devices. DAs in stand-alone mode are included in PDMODULE.

Some of the alarms that are logged due to PDMODULE and TDMODULE test failures may be related to circuit-pack problems reported during DIG-BD testing. See [XXX-BD \(Common Port Circuit Pack/Media Module\)](#).

Error log entries and tests also apply to TDMODULE.

The PDMODULE and TDMODULE MOs monitor and test Digital Line circuit pack ports that are connected to Data Communications Equipment (DCE) or Data Terminal Equipment (DTE). DCE include processor data modules (MPDM) and Data Adaptors (DA). DTE include trunk data modules (DTE). These stand-alone data modules provide interfaces between DCP ports on the Digital Line circuit packs and data equipment such as terminals, host computers, and data modems. (See the following list and figure.) Data modules are used for dial-up and permanent circuit-switched data calls.

Digital Line circuit packs also connect to digital terminal data modules (DTDMs), which work in conjunction with a voice terminal. Those configurations are covered by the DIG-LINE MO. Circuit pack-level maintenance is covered by DIG-BD whose strategy is described in the [XXX-BD \(Common Port Circuit Pack/Media Module\)](#).

Digital line circuit packs include the TN754, TN754B, TN413, TN2136. See [DIG-LINE \(Digital Line\)](#) for more information about the characteristics of these circuit packs.

**Note:**

Not all tests that run on circuit packs are applicable to media modules. These tests will abort with error code 1412. This error can be ignored.

---

## Stand-Alone DCP Data Modules

There are two types of stand-alone DCP data modules as shown in [Table 201](#).

**Table 201: Stand-Alone DCP Data Modules**

| Type | Name <sup>1</sup>             | Interfaces to:                                       |
|------|-------------------------------|------------------------------------------------------|
| MPDM | Modular Processor Data Module | DTE (data terminals, host computers, printers, etc.) |
| MTDM | Modular Trunk Data Module     | DCE (modems, data modules, etc.)                     |

1. Early versions of these data modules were referred to as PDMs and TDMs, respectively. Later models are designed to provide a variety of interfaces by using interchangeable modules and are thus called modular data modules.

---

## Data Adapters

TN2136 circuit packs use IDCP signaling and a DAA2 Data Adaptor (DA) to interface to DTE. DAs can operate in either of two modes which are covered by different MOs:

**Table 202: Data Adaptor Modes**

| DA Mode     | Administered as: | Endpoint                                       | Maintenance Object |
|-------------|------------------|------------------------------------------------|--------------------|
| Stand-Alone | PDM              | data endpoint only                             | PDMODULE           |
| Linked      | DTDM             | IDT1/2 <sup>1</sup> and optional data terminal | DIG-LINE           |

1. IDT1/2: Italtel Digital Telephone, Model 1 or 2 (also known as Digital Telephones TD7210 and TD7206).

---

## Configurations and Maintenance

The MPDM provides an interface for Data Terminal Equipment (terminals), and the MTDM (see Note) provides an interface for Data Communications Equipment (transmission equipment such as modems).

**Note:**

Early versions of these data modules were referred to as PDMs and TDMs, respectively. Later models are designed to provide various customer interfaces through the use of interchangeable interface modules and, therefore, are called modular data modules.

In the following discussion, the general term data module refers to MPDMs, MTDMs, and DAs. The PBX loop or digital link between a data module and the Digital Line port supports two logical information channels and one signaling channel. Data modules generally use the primary information channel for data communications and the signaling channel for dialing and call supervision. With 4-wire DCP, the secondary information channel can be used to support a second data module on a shared port.

Besides being used for data calls between terminals, computers, and data communications equipment, data modules also serve as interfaces to equipment associated with system features such as System Administration, Station Message Detailed Recording, Message Center Service, Automatic Call Distribution, Distributed Communications System, and Audio Information Exchange. Maintenance for data modules associated with these latter services are covered by other MOs such as PMS-PRNT, JNL-PRNT, and PMS-LINK.

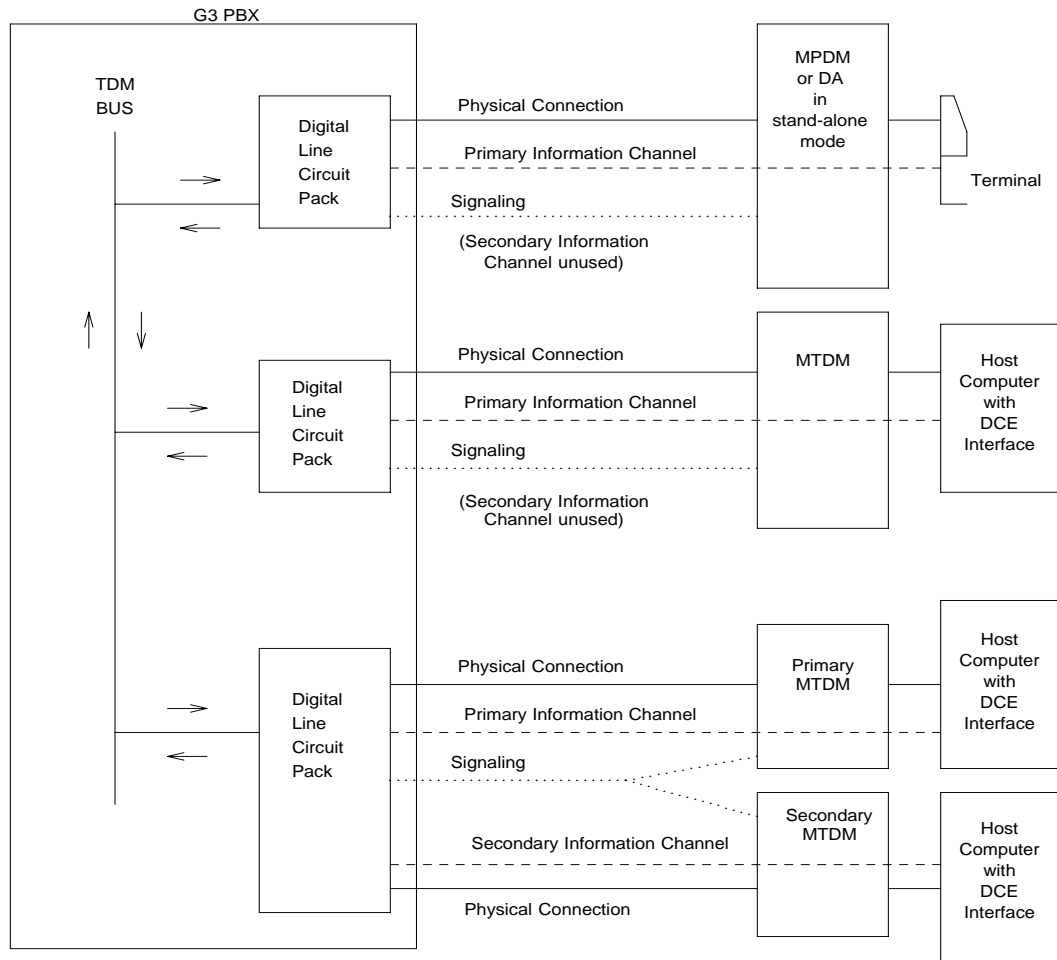

Maintenance of data modules is closely related to and interacts with Digital Line circuit pack maintenance, and test results for data modules can be affected by the health of the Digital Line circuit pack. Keep this interaction in mind when investigating customer-reported problems with data modules.

Data modules provide a variety of option switches to allow the customer to select data rates, parity, keyboard dialing, local, and remote loopback, etc. (The DAA2 Data Adaptor has an AT (Hayes) type interface that allows selection of the above parameters as well as mode linked or stand-alone.) An incorrect selection will not necessarily cause errors, alarms or test failures, but it can result in service disruption. See the installation manual provided with the data module for more information about those options.

This discussion occasionally refers to a station's service state, defined as:

|                |                                                                                                                                                                                                                                                                                                                                                    |
|----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Out-of-Service | The port, and thus the data module, have been removed from service. Causes for this include busyout of the port, removal of the Digital Line circuit pack, and failure of the GPP NPE Crosstalk Test (#9).                                                                                                                                         |
| Disconnected   | The port is administered but the associated digital link does not respond. An administered port is put in a disconnected state after a system reboot or circuit pack insertion. This state persists until a link-reset-pass message is received from firmware on the circuit pack.                                                                 |
| In-Service     | When switch software receives a link-reset-pass message from the port, the port is placed in service. If the link-reset-pass message is missed, and an off-hook message is received while the port is in the disconnected state, maintenance software will run an ID request test and put the port into service upon receiving a correct response. |

Figure 52: Typical Data Module Configurations

## Error log entries and recommended actions

Table 203: PDMODULE, TDMODULE Error Log Entries 1 of 2

| Error Type | Aux Data | Associated Test | Alarm Level | On/Off Board | Recommended Action |
|------------|----------|-----------------|-------------|--------------|--------------------|
| 0 (a)      | 0        |                 |             |              |                    |
| 1 (b, n)   | 40987    |                 | WRN         | OFF          |                    |
| 1 (c, n)   | 1 – 20   |                 | WRN         | OFF          |                    |
|            |          |                 |             |              | <b>1 of 2</b>      |

**Table 203: PDMODULE, TDMODULE Error Log Entries 2 of 2**

| Error Type  | Aux Data | Associated Test                                  | Alarm Level | On/Off Board | Recommended Action       |
|-------------|----------|--------------------------------------------------|-------------|--------------|--------------------------|
| 15 (d)      | Any      |                                                  |             |              |                          |
| 18 (e)      | 0        | busyout port location                            | WRN         | OFF          | release port location    |
| 257 (f)     | 40971    |                                                  |             |              |                          |
| 513         | 0        | Digital Station Audits (#17)                     | WRN         | OFF          | test port location r 6   |
| 769 (g, n)  | 40988    |                                                  | WRN         | OFF          |                          |
| 1281        | Any      | Digital Station Audits (#17)                     | WRN         | OFF          | test port location r 4   |
| 1537 (h, n) | 40968    |                                                  | WRN         | OFF          |                          |
| 1793        |          | Information and Control Channel Looparound (#13) | MIN         | ON           | test port location 1 r 3 |
| 2049        |          | GPP NPE Crosstalk (#9)                           | MIN         | ON           | test port location 1 r 3 |
| 2304 (i)    |          |                                                  |             |              |                          |
| 2305 (j)    | 32770    |                                                  |             |              |                          |
| 2305 (k)    | 40967    |                                                  |             |              |                          |
| 2561 (l)    | Any      | Data Module Internal Looparound (#175)           | WRN         | OFF          | test port location 1 r 5 |
| 2817 (m)    |          | Link GPP Loop (#183) Against Links               | MAJ         | ON           |                          |
| 3841 (n)    |          |                                                  |             |              |                          |
|             |          |                                                  |             |              | <b>2 of 2</b>            |

Notes:

- a. **Error Type 0:** a Digital Line circuit pack that has ports administered has been removed since the Error Log was last cleared. Make sure that the circuit pack has been re-inserted.
- b. **Error Type 1, Aux Data 40987:** an off-board problem was detected by the port circuit, and may result in a noisy port or link. See Note (n) for recommendations.

**Note:**

Refer to the *DEFINITY® Communications System Generic 1 and Generic 3i Wiring*.

- c. **Error Type 1, Aux Data 1 - 20** is logged when at least 15 off-board problems have been detected with the link to the data module. Each error detected increments an on-board counter. The aux data gives the value of this counter divided by 15. The user could experience a noisy port or link. See Note (n) for recommendations.

**Note:**

Refer to the *DEFINITY® Communications System Generic 1 and Generic 3i Wiring*.

- d. **Error Type 15:** an internal error that occurs when an audit request fails.
- e. **Error Type 18:** the port in question is demand busied out. Release the port with **release port location**.
- f. **Error Type 257:** problems with transmitting to the data module. This is usually an on-board problem and can be ignored if no user complaints are received. Otherwise, check for faulty wiring.
- g. **Error Type 769:** EPF has been turned off due to the overcurrent condition at the data module. See the recommendations in note n. This may also be caused by the PTC being in the “tripped” position due to a short on the power line. You can correct this by removing the short, unplugging the data module from the wall for about 30 seconds, and plugging it back in.

**Note:**

Refer to the *DEFINITY® Communications System Generic 1 and Generic 3i Wiring*.

- h. **Error Type 1537:** there is a problem with the link to the data module. This can be ignored if no user complaints are received. Otherwise, see Note (n) for recommendations.

**Note:**

Refer to the *DEFINITY® Communications System Generic 1 and Generic 3i Wiring*.

- i. **Error Type 2304:** internal error. No action is necessary.
- j. **Error Type 2305, Aux Data 32770:** the data equipment went off-hook while the associated link was being initialized (in a disconnected state). Use **status data-module** to determine the state of the data module. The off-hook should have changed the service state to in-service. No action is necessary.
- k. **Error Type 2305, Aux Data 40967:** the link between the circuit pack and the data module has been reset successfully. The link is normally reset when the circuit pack associated with an administered port is first plugged in (assuming that the data module is already in place and connected to the associated port), when a port is first administered (assuming the associated circuit pack is plugged in and that the data module is connected to the

associated port), or when a data module is first connected to an administered port. No action is necessary.

l. **Error Type 2561**: the downlink buffer on the circuit pack has overflowed. No action is necessary.

m. **Error Type 2817**: a DCP endpoint may have been disconnected.

n. **Error Type 1, 769, 1537, 3841**: make sure the data module is connected and operating properly. Check for faulty wiring. If necessary, reduce the length of the cable between the data module and the switch to 5000 ft. for 24-gauge wire or 4000 ft. for 24-gauge wire.

If the problem still exists, replace the circuit pack. Once the problem has been resolved, the alarm will be retired in 60 minutes (90 min. for error 1537).

The DA module is not phantom-powered from the port. Thus when it is in linked mode, its range is limited by the Italtel digital phone's limit: 0.7 Km (2300 ft.) on 26-gauge wire or 1.8 Km (5900 ft.) on 22-gauge (0.6 mm) wire. If in stand-alone mode, it is limited by the maximum length of loop allowed from the Digital Line Interface (DLI) component: up to 3.5 km (2 miles) on 22-gauge (0.6 mm) wire.

---

## Demand test descriptions and error codes

Investigate tests in the order presented. By clearing errors associated with the first test, errors generated from other tests may also be cleared. Click on the link to see the full description of the test, error codes, and recommended actions.

| Order of Investigation                                      | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|-------------------------------------------------------------|---------------------|--------------------|-------------------|
| <a href="#">Data Module Internal Looparound Test (#175)</a> |                     | X                  | ND                |
| <a href="#">GPP NPE Crosstalk Test (#9)</a>                 |                     | X                  | ND                |
| <a href="#">Local Loop Test (#13)</a>                       |                     | X                  | ND                |
| <a href="#">Digital Station Audits Test (#17)</a>           | X                   | X                  | ND                |

1. D = Destructive; ND = Nondestructive

## \_PE (Processor Ethernet) Alarms

The \_PE alarms are raised for the following servers:

- 1 S8720
- 1 S8730

---

### PE interface alarms

**\_PE 1 Minor alarm: PE Health Check device is not responding.**

| MO name in log | Alarm level | Alarm text                             | Description                                                                                            |
|----------------|-------------|----------------------------------------|--------------------------------------------------------------------------------------------------------|
| _PE 1          | MIN         | Can't ping the PE Health Check device. | Processor Ethernet (PE) Health Check device is not responding. Cannot ping the PE Health Check device. |

Resolution:

1. Log on to System Management Interface.
2. From the Installation menu, click **Configure Server**. The Configure Server wizard opens.
3. On the Configure Interfaces screen, verify if **IP address for PE Health Check** is set to the gateway address.
4. Execute the Ping diagnostics test to verify that the endpoint used for the PE Health Check device (the gateway) responds to a ping request. For more information about the Ping diagnostics test, see the System Management Interface **Help**.

**\_PE 2 Minor alarm: PE on other server is not responding.**

| MO name in log | Alarm level | Alarm text                                                             | Description                                                                                                                                            |
|----------------|-------------|------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------|
| _PE 2          | MIN         | Can't ping the other server over the network used by the PE Interface. | Processor Ethernet (PE) on the other server is not responding. Cannot ping the other server over the network used by the Processor Ethernet interface. |

Resolution:

1. Log on to the System Management Interface.
2. Click the **Administration** tab and select **Server (Maintenance)**.
3. On the left navigation menu, click **Status Summary**. The Status Summary screen appears.
4. Verify that the other server in the duplicated server pair is running and that the Processor Ethernet status is not **Down**.
  1. If the other server in the duplicated server pair is not running, the status of Mode is **Not Ready** and the display of items such as "Alarms" are blank.
  1. If the Processor Ethernet status is not **Down**, run the troubleshooting procedures for the alarms on the other server.  
For more information about the troubleshooting procedures, see *Avaya Aura™ Communication Manager Server Alarms, (03-602798)*.
5. Execute the Ping diagnostic test to verify that the other server responds to a ping test. If it does not, execute the Ping diagnostics test from the other server to verify that it is connected to the corporate LAN.

**\_PE 3 Major alarm - Processor Ethernet service is down**

| MO name in log | Alarm level | Alarm text                                                                                                  | Description                                                                                                                          |
|----------------|-------------|-------------------------------------------------------------------------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------|
| _PE 3          | MAJ         | Can't ping the device used for the PE Health Check or the IP interface used for the PE on the other server. | Processor Ethernet service is down. Cannot ping the PE Health Check device and the IP interface used for the PE on the other server. |

Resolution:

1. Run the tests listed for the alarms associated with \_PE 1 and \_PE 2.
2. Verify if that the server is connected to the corporate LAN.
3. If NIC alarms are present, follow the troubleshooting procedures for those alarms. For more information, see [Verify NIC Options Test \(#1511\)](#) on page 1676.
4. Verify that the corporate LAN is working.

---

## PE Interchange Priority Mismatch Alarm

### \_PE 4 Minor alarm: PE Priority configuration mismatch between servers

| MO name in log | Alarm level | Alarm text | Description                                                                                                                                                                                                                                                                                              |
|----------------|-------------|------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| _PE 4          | MIN         | None       | The PE Interchange Priority setting on the Configure Interfaces page of the System Management Interface of one of the servers of a duplicated pair of server does not match the PE Interchange Priority setting on the Configure Interfaces page of the System Management Interface of the other server. |

**Resolution:**

1. On the Status Summary screen of System Management Interface, verify that the PE Interchange Priority setting on the active server is the same as the PE Interchange Priority setting on the standby server.
2. On the Configure Interface screen of System Management Interface (that displays the incorrect value) change the incorrect value of the PE Interchange Priority setting.

**Note:**

Make sure that the server on which you are changing the settings on the Configure Interface screen is on the standby server.

## PE-BCHL (PRI Endpoint Port)

| MO Name in Log       | Alarm Level | Initial Command to Run               | Full Name of MO   |
|----------------------|-------------|--------------------------------------|-------------------|
| PE-BCHL <sup>1</sup> | MIN         | <code>test port location long</code> | PRI Endpoint Port |
| PE-BCHL              | WRN         | <code>test port location</code>      | PRI Endpoint Port |

1. For additional repair information, see also [UDS1-BD \(UDS1 Interface Circuit Pack\)](#) and [Troubleshooting ISDN-PRI endpoints \(wideband\)](#) in *Maintenance Procedures (03-300432)*.

A PRI endpoint provides ISDN-PRI (Primary Rate Interface) connections application equipment or terminal adapters that terminate ISDN PRI. The equipment or terminal adapters are connected to the switch via the TN464C/D UDS1 interface circuit pack. This MO monitors the PRI endpoint's port hardware on the UDS1 circuit pack by:

- 1 Logging hardware errors
- 1 Running tests for port initialization
- 1 Running periodic and scheduled maintenance
- 1 Executing demand tests

---

## Wideband Switching

Wideband switching supports end-to-end connectivity between customer endpoints at data rates from 128 to 1536 kbps over T1 facilities and to 1984 kbps over E1 facilities. Switching capabilities support wideband calls comprised of multiple DS0s that are switched end-to-end as a single entity.

Wideband switching is designed for ISDN application equipment such as ISDN video codecs, but can also interface to non-ISDN application equipment by using PRI terminal adapters. In the same sense that a data module acts as a DCP or BRI terminal adapter between endpoint data, such as V.35 and dialing interfaces such as RS-366 and a DCP interface, a PRI terminal adapter acts as a wideband terminal adapter between endpoint data and dialing interfaces and a line-side ISDN-PRI interface. Wideband switching introduces PRI endpoints on line-side interfaces.

A PRI endpoint has a unique extension number and consists of one or more contiguous B-Channels on a line-side T1 or E1 ISDN-PRI facility. Endpoints initiate and receive calls via ISDN SETUP messages indicating the data rate and specific B-Channels to be used, and communicate all other call status information via standard ISDN messages. Any ISDN signaling set such as Avaya, CCITT, or ECMA may be used for a line-side ISDN-PRI facility.

Multiple PRI endpoints on one line-side facility are separate and distinct within the facility. Non-overlapping contiguous sets of B-Channels are associated with each PRI endpoint, and the endpoint equipment is expected to initiate calls within these boundaries. The endpoint application equipment must:

- 1 Use standard ISDN-PRI signaling
- 1 Adhere to the administered PRI endpoint boundaries when initiating calls
- 1 Handle incoming calls appropriately, based on the originating PRI endpoint

---

## Signaling and B-Channel States

PRI ports use a separate channel called the D-Channel for call-control and signaling messages. This is called out-of-band signaling. The D-Channel associated with the set of B-Channels is an ISDN-PRI signaling link's port (ISDN-PLK). The signaling protocol used on the ISDN-PRI signaling-link port's D channel is defined by one of the four selectable ISDN-PRI Specifications: Avaya, CCITT, ECMA, and ANSI.

The ISDN-PRI Specification defines the possible service states for a B-Channel. The service state is negotiated with the far-end terminal adapter, changes over time, and can have far- and near-end components. The service state is initialized to Out-Of-Service/Far-End, and an attempt is made to negotiate it to In-Service. Use `status pri-endpoint extension` to display the service state of a particular PRI endpoint port's B-Channel.

If a call is present, the Specification defines the permissible call states as well. There are tests in the short and long test sequences for the PRI endpoint port designed to audit these states and ensure agreement between both ends of the PRI wideband connection.

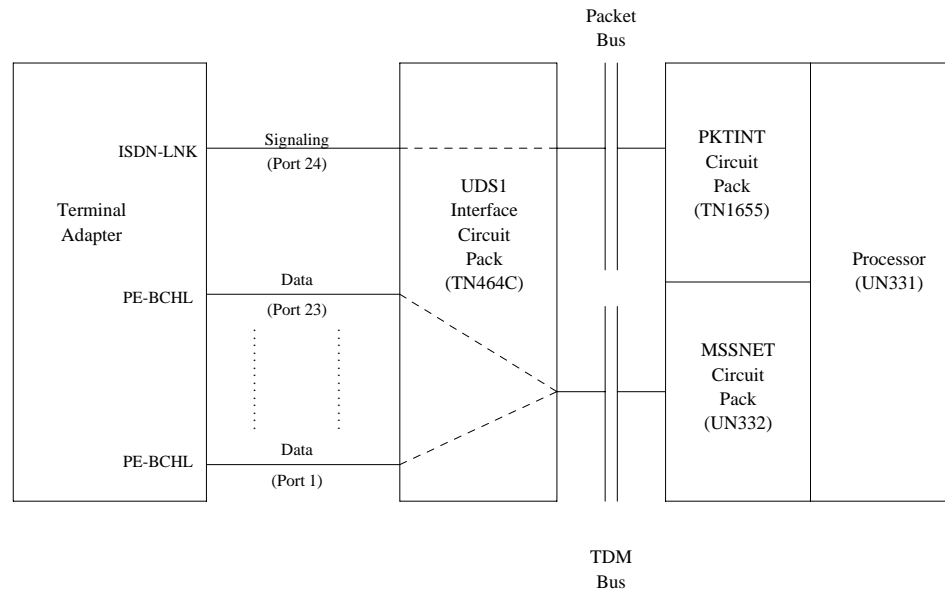

---

## Alarming Based on Service States

A PRI endpoint port's B-Channel logs a warning alarm when it is placed in a Maintenance/Far-End or Out-Of-Service/Far-End state. While in such a state, the port is unusable for calls to the terminal adapter. However, the user can still use the other remaining ports in the PRI endpoint to make calls to and from the terminal adapter. When a warning alarm is raised, use `status pri-endpoint extension` to determine the exact state of the port. Other alarms can be diagnosed by using the short and long test sequences. Note that a PRI endpoint port's B-Channel can be placed in a far-end service state by direct action by the far-end terminal adapter or by inaction of the far-end terminal adapter. For example, if it does not respond to a Remote Layer 3 Query (see [Remote Layer 3 Query \(#637\)](#) for ISDN-PLK) the associated PRI endpoint port's B-Channels will be placed in the Maintenance/Far-End service state.

A PRI endpoint port is a port on a UDS1 interface circuit pack and thus depends on the health of the circuit pack for proper operation (see the following figure). A problem on the associated ISDN-LNK's (ISDN-PRI signaling-link port's) D-Channel can also affect the PRI endpoint. In turn, the ISDN-PLK depends on the SYS-LINK (system link) to the packet interface. Keep this hierarchy of dependencies in mind when diagnosing problems.

**Figure 53: PRI Endpoint Port Interactions**

## PRI Endpoint Port Service States

The `status pri-endpoint extension` command displays the following possible service states for PRI endpoint ports. The table that follows gives recommended procedures for each state. The figure following that shows typical progressions from one service state to another. Refer also to [Troubleshooting ISDN-PRI endpoints \(wideband\)](#) in *Maintenance Procedures (03-300432)* for a layered approach to addressing PRI endpoint problems.

- 1 In-Service (INS)

The B-Channel is in its normal operating state.

- 1 Out-of-Service/Far-End (OOS/FE)

A B-Channel is initialized to this state when first administered. The switch then sends messages to the far-end terminal adapter to negotiate the B channel into service. If the far-end terminal adapter does not respond to the messages within a certain time period, the port remains out of service, and maintenance will periodically resend the messages. The port is unusable for incoming and outgoing calls, although other ports in the PRI endpoint can still be used.

## 1 Out-of-Service/Near-End (OOS/NE)

This is the state of the port when a hardware failure exists on the signaling link, the NPE Crosstalk test fails, or when the port is busied out by command. In this state, the port is unusable for calls coming into the switch or going out to the terminal adapter, although other ports in the PRI endpoint can still be used for incoming and outgoing calls. No messages are sent to the far-end terminal adapter until the signaling link comes back into service or the port is released by command.

## 1 Maintenance/Far-End (MTC/FE)

This state is reached when the far-end terminal adapter does not respond to messages sent over the signaling link for a particular port within a certain amount of time. This state is different from OOS/FE since the signaling link must have initially been up and the B-Channels in service. The switch will periodically send messages to the far-end terminal adapter to try to negotiate the port (B-Channel) into service. The port is unusable for outgoing calls to the terminal adapter but will service incoming call requests from the far end. Other ports of the PRI endpoint can still place outgoing calls to the terminal adapter. Transitions into MTC/FE do not drop stable calls. If the service state changes from in-service to MTC/FE, stable calls are unaffected.

## 1 Maintenance/Near-End (MTC/NE)

Use **busyout**, **test port 1** or **test pri-endpoint 1** to busy out the signaling link (SYS-LINK). Transitions into MTC/NE do not drop stable calls. The **busyout link link-no** command does not drop stable wideband calls. In this state, the B-Channel is not usable for new incoming calls to the switch or new outgoing calls to the terminal adapter.

1 Pending States (PEND)

If the near end is expecting a timed response from the far end for a request to change the service state of a port, a *pending* state is in effect. For example, if the port is out-of-service/far-end and an in-service message was sent to the far end, then the service state of the port is OOS/FE-PEND/INS meaning out-of-service/far-end, pending/in-service. The service state will reflect this pending state until the far end responds or the timer expires.

**Table 204: PRI Endpoint Port Service States 1 of 2**

| Service State      | Alarm | Possible Cause                                                                                                    | Possible Solution                                                                                                                                                          |
|--------------------|-------|-------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>OOS/NE</b>      | WRN   | Port has been busied out by command.                                                                              | Enter <b>release pri-endpoint extension</b> .                                                                                                                              |
|                    | MIN   | NPE Crosstalk test (#6) failed.                                                                                   | Replace UDS1 circuit pack.                                                                                                                                                 |
|                    |       | UDS1 circuit pack lost its signal.                                                                                | Is the UDS1 circuit pack removed? Is the UDS1 cable disconnected? Is the far-end terminal restarting or experiencing problems? Check circuit pack using UDS1-BD procedure. |
| <b>OOS/FE</b>      | WRN   | Far-end problems or incompatibility                                                                               | Check administration and status of the corresponding port on the terminal adapter.                                                                                         |
|                    | WRN   | The far-end port is busied out.                                                                                   | Check the status of the far-end terminal adapter.                                                                                                                          |
| <b>OOS/FE PINS</b> |       | Service message was sent and the switch is waiting up to 2 minutes for a reply from the far-end terminal adapter. | Wait 2 minutes, and check service state after the PINS state has cleared.                                                                                                  |
| <b>MTC/NE</b>      |       | System link demand busied out                                                                                     | Check link status. Release with <b>release link link#</b> .                                                                                                                |
| <b>MTC/FE</b>      | WRN   | Signaling channel has been down for over 90 sec.                                                                  | Consult ISDN-SGRP, ISDN-SLK and/or SYS-LINK. Far-end terminal adapter may currently be restarting.                                                                         |
|                    | WRN   | Repeated failure of far end to respond to messages.                                                               | Maintenance software will periodically try to resend messages. You can speed the process with <b>test port location</b> (Test #256).                                       |
|                    | WRN   | The far-end port is being tested.                                                                                 | Check status of the far-end terminal adapter.                                                                                                                              |
| <b>1 of 2</b>      |       |                                                                                                                   |                                                                                                                                                                            |

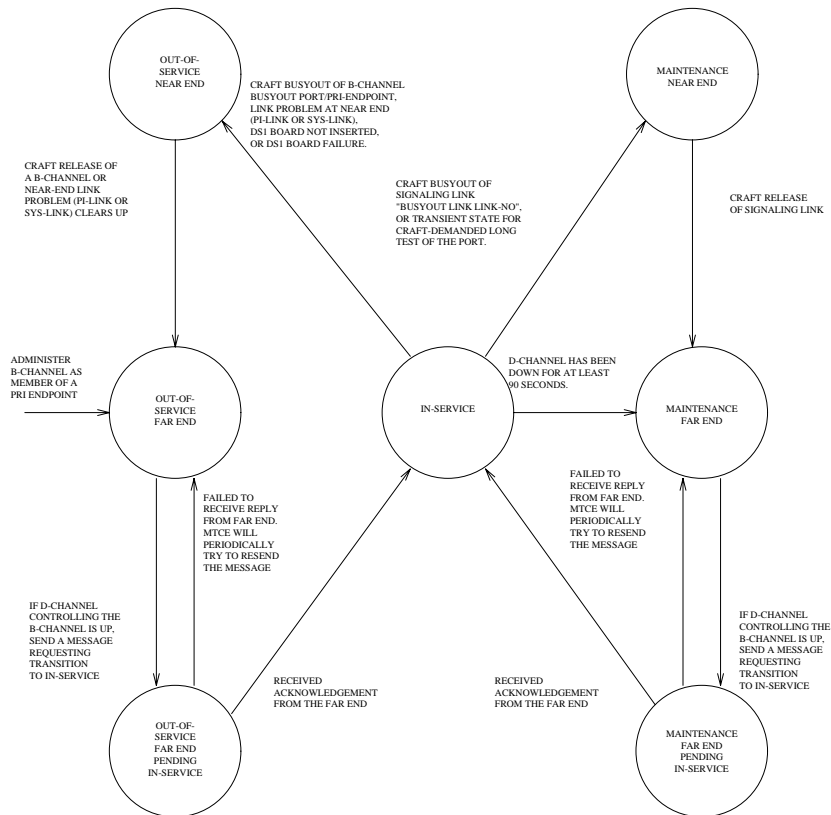

Table 204: PRI Endpoint Port Service States 2 of 2

| Service State      | Alarm | Possible Cause                                                                                                     | Possible Solution                                                         |
|--------------------|-------|--------------------------------------------------------------------------------------------------------------------|---------------------------------------------------------------------------|
| <b>MTC/FE PINS</b> |       | Service message was sent, and the switch is waiting up to 2 minutes for a reply from the far-end terminal adapter. | Wait 2 minutes, and check service state after the PINS state has cleared. |
| <b>INS</b>         |       | Normal operating state. ISDN wideband calls are completing.                                                        |                                                                           |

| 3585 (m)   | Any      |                                                                             |             |              |                                                                     |

Notes:

- a. **Error Type 0:** run the short test sequence first. If every test passes, run the long test sequence. Refer to each test's description and follow its procedures.
- b. **Error Type 1:** disagreement between this switch and the terminal adapter at the other end of the connection with regard to the ISDN call state of the PRI endpoint port. This switch will

automatically try to recover by clearing the call (the call will be torn down). Use `status pri-endpoint extension` to determine the state of the port.

When running the short test sequence, note the results of the [Call State Audit Test \(#257\)](#).

- c. **Error Type 15:** software audit error that does not indicate any hardware malfunction. Run the short test sequence, and investigate associated errors.
- d. **Error Type 18:** the PRI endpoint port has been busied out by `busyout pri-endpoint extension` or `busyout port location`. No wideband calls can be made to this port, although wideband calls can still be made to other ports within this PRI endpoint if they are in service. Release the port with `release port location`.
- e. **Error Type 129:** the far-end terminal adapter changed its ISDN *service* state to out-of-service or maintenance. This may be a temporary condition due to testing of this port by the far-end terminal adapter or a hardware problem with the port. Outgoing calls to the terminal adapter will not be allowed over the port, although calls can still be made to other ports that are in service within the same PRI endpoint. To investigate the status of the port, enter `status pri-endpoint extension`.
- f. **Error Type 130:** the circuit pack has been removed or has been insane for more than 11 minutes. To clear the error, reinsert or replace the circuit pack.
- g. **Error Types 257, 769:** disagreement between this switch and the terminal adapter at the other end of the connection with regard to the ISDN service state of the PRI endpoint port. The switch will automatically try to recover by performing a service state audit. Use `status pri-endpoint extension` to determine the state of the port.

When running the short test sequence, note the results of the [Service State Audit Test \(#256\)](#).

- h. **Error Type 513:** This port is not recognized by the far-end terminal adapter. Investigate the PRI endpoint administration for both the switch and the terminal adapter, and make sure they agree.
- i. **Error Type 1281:** The Conference Circuit test (#7) failed on this port. See [Conference Circuit Test \(#7\)](#) for repair procedures.
- j. **Error Type 1537:** The NPE Crosstalk test (#6) failed on this port. See [NPE Crosstalk Test \(#6\)](#) for repair procedures.
- k. **Error Type 1793:** failure of the UDS1 Interface circuit pack. Run the short test sequence and note the results of the [Signaling Link State Audit Test \(#255\)](#).
- l. **Error Type 3073:** Two Service State audit attempts have failed (see [Service State Audit Test \(#256\)](#)). The port will not be usable for any outgoing calls to the terminal adapter until the test passes and the port state is changed to in-service. Incoming calls from the terminal adapter *will* be accepted over this port, and other ports in the PRI endpoint can still be used for both incoming and outgoing calls to and from the terminal adapter.

- m. **Error Type 3585:** the switch received an ISDN RESTART message for an ISDN port that is not idle. Because calls are not typically cleared with the RESTART message, this Error Type may be associated with a dropped call report from a user.

The following Aux Data values for Error Type 3585 represent the port's ISDN call state at the time the unexpected RESTART request was received from the terminal adapter. This information can be useful if dropped calls are being reported by users of the PRI endpoint. Aux Data values that do not appear below can be ignored.

**Table 206: PE-BCHL - Error 3585 Aux Data Values**

| Aux Data                            | Meaning                                                                                                                                                                                                                                                                                                                                         |
|-------------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 10                                  | A call in a stable, talking state (the <i>active</i> state) was cleared unexpectedly by the far-end terminal adapter with an ISDN RESTART message.                                                                                                                                                                                              |
| 4<br>7<br>8<br>260<br>263           | A call that has not reached the active state, but has at least reached a ringing state, was cleared unexpectedly by the far-end terminal adapter with an ISDN RESTART message.                                                                                                                                                                  |
| 1<br>3<br>6<br>265                  | A call that has not yet reached a ringing state was cleared unexpectedly by the far-end terminal adapter with an ISDN RESTART message.                                                                                                                                                                                                          |
| 11<br>12<br>19<br>267<br>268<br>531 | A call that was already in the process of clearing has been cleared by the far-end terminal adapter with an ISDN RESTART message. If this condition occurs frequently, it may mean that the far-end terminal adapter is attempting to clear ports that it thinks are in a "hung" state. The RESTART message puts the port in an idle condition. |

## Demand test descriptions and error codes

Investigate tests in the order presented. By clearing errors associated with the first test, errors generated from other tests may also be cleared. Click on the link to see the full description of the test, error codes, and recommended actions.

| Order of Investigation                                 | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|--------------------------------------------------------|---------------------|--------------------|-------------------|
| <a href="#">NPE Crosstalk Test (#6)</a>                |                     | X                  | ND                |

1. D = Destructive; ND = Nondestructive

## PKT-BUS (Packet Bus)

| MO Name in Log | Alarm Level | Initial Command to Run <sup>1</sup>           | Full Name of MO |
|----------------|-------------|-----------------------------------------------|-----------------|
| PKT-BUS        | MAJ         | <code>test pkt P long r 2</code> <sup>1</sup> | Packet Bus      |
|                | MIN<br>WRN  | <code>test pkt P long</code>                  |                 |

1. *P* is the port-network number indicated in the PORT field from the Alarm or Error Log.

The packet bus consists of a single bus, and one such bus appears in each port network. The packet bus in each port network is physically independent from those in other port networks, so each port network has a separate PKT-BUS MO. This bus supports the following types of connections:

- 1 Logical control links between the server and every PN
- 1 ISDN-BRI D-channel transport (signaling)
- 1 ASAI D-channel transport (signaling)
- 1 ISDN-PRI D-channel (signaling)
- 1 System Access Ports

The TN2312AP IPSI circuit pack's Packet Interface circuit provides an interface to the packet bus for the server. Packet bus testing depends on the TN771D Maintenance/Test circuit pack. Packet Bus tests will abort if the TN771D circuit pack is not inserted in the port network.

The interactions between the packet bus and the circuit packs that use the bus are complex. Circuit pack failures can alarm the packet bus, while packet bus faults can alarm or interrupt service to one or more circuit packs and their ports and endpoints. The [Isolating and repairing packet-bus faults](#) section in *Maintenance Procedures (03-300432)* describes packet bus maintenance and interactions with circuit packs. That section should be referenced for all troubleshooting and repairs. The flowchart is the normal starting point for experienced technicians.

This section on the PKT-BUS MO is limited to a description of the Error and Alarm Log entries and the test sequence for the packet bus. The following list summarizes some of the important points to consider when working with the packet bus.

- 1 The Maintenance/Test circuit pack (TN771D) is a critical tool for isolating packet bus faults. This circuit pack resides in each port network of a critical-reliability system (duplicated servers *and* PNC). If a TN771D is absent, *one must be taken to the customer site* to allow for proper fault isolation. [Isolating and repairing packet-bus faults](#) in *Maintenance Procedures (03-300432)* describes the Packet Bus testing facilities of the TN771D and when one must be taken to the customer site.

- 1 Certain catastrophic packet bus faults have an effect on maintenance software activities relating to packet circuit packs, ports, and endpoints:
  - Packet circuit pack (BRI-BD, UDS1-BD) inline errors indicating possible Packet Bus test failures are logged in the error log, but are not acted upon.
  - Port-level (BRI-PORT, ABRI-PORT) inline errors on Packet circuit packs which indicate possible Packet Bus failures are not logged or acted upon.
  - Circuit pack and port inline errors that are not relevant to the Packet Bus, or that indicate a circuit pack failure, are acted upon in the normal fashion.
  - Periodic and scheduled background maintenance are not affected.
  - Foreground maintenance (for example, a `test board` command executed at a terminal) is not affected.

The actions in the previous list serve to reduce the system load, which could become excessive if many MOs are affected by a packet bus failure. However, such an excessive load should in no way impede the isolation and the correction of the faults.

When the above actions are implemented, Error Type 3329 is logged against PKT-BUS, and a Warning alarm is raised. Other Packet Bus errors may raise more severe alarms, thereby overriding the Warning alarm.

- 1 **S8700-series Fiber-PNC**: Since all packet traffic requires communication with the IPSI's PKT-INT circuit in an IPSI connected PN, a PKT-BUS failure in the IPSI connected PN causes packet traffic in this PN, and every PN controlled by the IPSI connected PN, to fail. In the S8700 Fiber-PNC configuration where some PNs are non IPSI connected, an IPSI connected PN PKT-BUS fault should be investigated first whenever PKT-BUS problems occur in multiple PNs.

## Error log entries and recommended action

Table 207: PKT-BUS Error Log Entries 1 of 2

| Error Type | Aux Data | Associated Test                                 | Alarm Level | On/Off Board <sup>1</sup> | Recommended Action                         |
|------------|----------|-------------------------------------------------|-------------|---------------------------|--------------------------------------------|
| 0 (a)      | 0        | Any                                             | Any         | Any                       | <code>test pkt port-network</code>         |

| 1793 (d)   | Any      |                                                 |             |                           |                                            |

**1 of 2**

**Table 207: PKT-BUS Error Log Entries 2 of 2**

| Error Type | Aux Data | Associated Test                                 | Alarm Level | On/Off Board <sup>1</sup> | Recommended Action            |
|------------|----------|-------------------------------------------------|-------------|---------------------------|-------------------------------|
| 2049 (e)   | 1–3      | Maintenance/Test Circuit Pack Query test (#572) | MIN         | ON                        | test pkt port-network P 1 r 2 |
| 2305 (f)   | 1–2<br>4 | Maintenance/Test Circuit Pack Query test (#572) |             |                           | test pkt port-network P 1     |
| 3329 (g)   | 1–7      |                                                 | WRN         | ON                        | test pkt port-network P 1     |
| 3585 (h)   | Any      |                                                 | MIN         | ON                        | test pkt port-network P 1     |
| 3841 (i)   | Any      |                                                 | MIN         | OFF                       |                               |
|            |          |                                                 |             |                           | <b>2 of 2</b>                 |

1. ON-BOARD indicates a problem with the packet bus itself.

Notes:

- a. **Error Type 0:** Run the short test sequence first. If every test passes, run the long test sequence. Refer to each test’s description and follow its procedures.
- b. **Error Type 1:** Within the last minute, packet circuit packs have reported errors that indicate a possible packet bus failure. The Aux Data value is 1 or 2, indicating that only one or more than one Packet circuit pack (respectively) have reported a possible packet bus failure.
- c. **Error Type 513:** The Maintenance/Test packet bus port (M/T-PKT) for this port network has determined that there are more packet bus faults than the port can correct. The Aux Data value indicates the number of faulty leads.
- d. **Error Type 1793:** Packet circuit packs have detected possible packet bus failures via inline error or via background test failure. Examine the Error and Alarm logs for more specific PKT-BUS errors.
- e. **Error Type 2049: S8700-series Fiber-PNC:** The Maintenance/Test packet bus port (M/T-PKT) has detected a Packet Bus fault and has taken corrective action by swapping to spare leads. This error appears only in high/critical-reliability systems (duplicated PNC). The Aux Data value indicates the number of faulty leads. If this is the only active error against the packet bus, *the packet bus is still in service*. Due to the disruptive nature of the packet bus Fault Isolation and Correction procedures, repairs should be deferred until a time when the least interruption in service would result. This should be determined by consultation with the customer. However, do not delay repairs for too long, since the switch cannot recover from another packet bus failure until the current one is resolved. [Isolating and repairing packet-bus faults](#) in *Maintenance Procedures (03-300432)* contains a sub-section, *Special Precaution Concerning the TN771D* that describes how to ensure that the TN771D is providing correct information. A new TN771D may need to be taken to the customer site.

- f. **Error Type 2305:** The Maintenance/Test packet bus port (M/T-PKT) has detected open leads on the packet bus. The Aux Data value indicates the number of open leads.
- g. **Error Type 3329:** Packet circuit pack, port, and endpoint maintenance has been disabled due to a packet bus failure. The Aux Data value indicates the cause:

| Aux Data | Cause                                                                                                                                                                                                 |
|----------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1        | inline errors from packet circuit packs                                                                                                                                                               |
| 2        | Uncorrectable packet bus fault reported                                                                                                                                                               |
|          | Maintenance/Test packet bus port (M/T-PKT)                                                                                                                                                            |
| 3        | Both of the above                                                                                                                                                                                     |
| 100x     | Packet-related circuit pack, port, and endpoint maintenance in the PN has been disabled due to a packet bus failure in the PN. The last digit has the same meaning as the single digits listed above. |

Keep in mind that although only packet circuit packs can detect and report packet bus problems, such problems can be caused by any circuit pack.

- h. **Error Type 3585:** Packet circuit pack, port, and endpoint maintenance has been disabled due to more than one circuit pack reporting inline errors. If this occurs more than three times in 15 minutes a Minor alarm is raised against the packet bus. This happens when maintenance is disabled due to errors and is then re-enabled because no more errors are reported.

This error may still be present in the error log even though the [Packet Circuit Pack Audit Test \(#573\)](#) indicates that only one circuit pack is reporting a problem. This happens when more than one circuit pack has reported errors in any 1-minute interval since the packet bus fault occurred.

- i. **Error Type 3841:** The Maintenance/Test packet bus port (M/T-PKT) for this port network is not in service. This alarm does not appear for PNs in standard- or high-reliability systems since a TN771D is not required there. The error indicates one or more of the following:
  - 1 The packet bus port has been busied out (indicated by Error Type 18), and a Warning alarm is active against M/T-PKT in the same port network. Release the port by entering `release port location 04`.
  - 1 The packet bus port has failed. Look for alarms against M/T-PKT, and attempt to resolve these alarms.
  - 1 The Maintenance/Test circuit pack was not recognized by the system at the last system restart. Replace the Maintenance/Test circuit pack.
  - 1 There is no Maintenance/Test circuit pack in this port network. One must be installed.

The TN771 must be installed before other packet bus alarms can be resolved. (Alarms against a given MO are not resolved until every alarm-generating condition has been cleared).

---

## Demand test descriptions and error codes

Investigate tests in the order presented. By clearing errors associated with the first test, errors generated from other tests may also be cleared. Click on the link to see the full description of the test, error codes, and recommended actions.

| Order of Investigation                                          | Short Test Sequence | Long Test Sequence | D/ND           |
|-----------------------------------------------------------------|---------------------|--------------------|----------------|
| <a href="#">Packet Circuit Pack Audit Test (#573)</a>           | X                   | X                  | Nondestructive |
| <a href="#">Maintenance/Test Circuit Pack Query Test (#572)</a> | X                   | X                  | Nondestructive |

## PKT-INT (Packet Interface)

| MO Name in Log | Alarm Level       | Initial Command to Run                       | Full Name of MO  |
|----------------|-------------------|----------------------------------------------|------------------|
| PKT-INT        | MAJ<br>MIN<br>WRN | <code>reset packet-interface location</code> | Packet Interface |

The Packet Interface (PKT-INT) MO resides on the TN2312 IP Server Interface (IPSI) circuit pack and serves as an interface between the server and the packet bus.

The functionality of the TN1655 PKT-INT and TN2182 Tone-Clock circuit packs are on the TN2312 IPSI circuit pack. The IPSI circuit pack also provides:

- 1 PKT-INT packet bus interface
- 1 Archangel TDM-bus interface
- 1 Tone-Clock functionality
- 1 Ethernet interface for connectivity to servers
- 1 Ethernet interface for connectivity to services laptop PCs
- 1 **S8700-series Fiber-PNC**: Maintenance board interface for communication with the PN's Maintenance board, in Carrier A or B only

The TN2312 IPSI circuit pack is inserted into a PN's Tone-Clock slot and provides an Ethernet interface back to the servers. The PKT-INT interface module on the IPSI is similar to TN1655 PKT-INT boards. However, the IPSI's PKT-INT module does not support DMI Mode-2/-3 data links.

The PKT-INT supports links used for call setup of each port located in a PN. Packet Interface failure prevents call set-up and tear-down from telephones and trunks connected to PNs.

In addition to affecting telephone service, a Packet Interface failure affects the service provided by circuit packs that connect to the Packet bus. For example, ISDN-PRI or ISDN-BRI service, service provided by the C-LAN or VAL or IPMEDPRO circuit packs, etc.

**S8700 | S8710 | S8720**: If the active IPSI's Packet Interface module causes a MAJOR alarm in a high- or critical-reliability system (with duplicated IPSIs), an IPSI interchange occurs if the standby IPSI's state of health (SOH) is high enough to permit the interchange. A MAJOR alarm due to a failure of the standby IPSI's Packet Interface module lowers the standby's state of health (SOH), preventing a subsequent interchange.

The links that pass through the Packet Interface are identified as application links or system links as follows:

- 1 Application links are endpoints that require connectivity to the server via the C-LAN board's Socket interface. These links pass over the packet bus, and through C-LAN ports. The following system features use application links:
  - Call Detail Recording (CDR)
  - Dial-up administration
  - Property Management System (PMS)
  - Journal printer
  - Wake-up log printer
  - Announcement circuit pack upload/download of recorded messages
  - IP phones
- 1 System links
  - Expansion Archangel links (signaling links for call setup of a PN's endpoints)
  - Center Stage Control Network (CSCN) links
  - ISDN-PRI D-channel signaling links
  - ISDN-BRI D-channel broadcast and point-to-point signaling links
  - Adjunct Switch Application Interface (ASAI) links
  - Remote Socket Control Link (RSCL) (C-LAN, VAL)
  - BRI (TRK and STA)

---

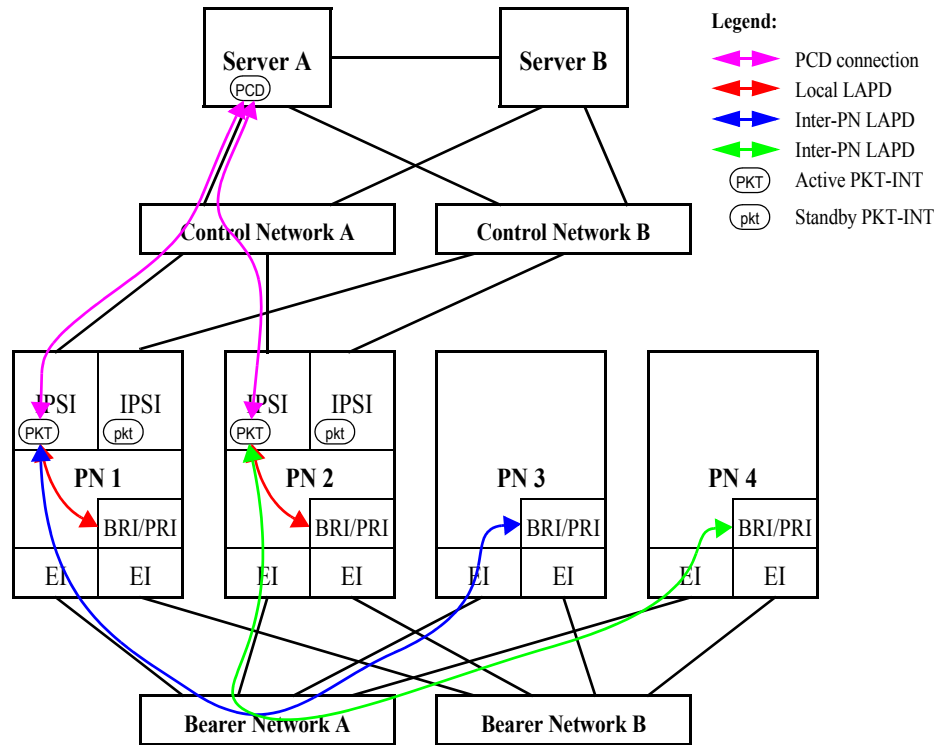

## Distributed PKT-INTs

LAPD links are terminated by the PKT-INT modules within IPSIs that are distributed out to the PNs, or out to every PN for the S8700 IP-PNC.

**S8700-series Fiber-PNC:** As shown in [Figure 55: Distributed PKT-INTs](#), PNs 1 and 2 have IPSIs that terminate LAPD links. PNs 3 and 4 do not have local IPSIs, so their LAPD links are terminated by IPSIs in PNs 1 and 2.

**S8700-series IP-PNC:** All port networks must have IPSI/PKT-INTs. They can be all simplex (one IPSI per PN) or all duplex (two IPSI per PN).

Figure 55: Distributed PKT-INTs

S8700-series Fiber-PNC

## PKT-INT Interchange

PKT-INT interchange is independent of server interchange, and a PKT-INT interchange can occur without a server interchange and vice versa. The active server's packet control driver (PCD) has sockets to both active and standby IPSIs and exchanges heartbeats with both. The active PCD is responsible for bringing up the active PKT-INT, and for bringing up the standby PKT-INT into the standby mode. The standby PCD also has sockets to both active and standby IPSIs and exchanges heartbeats with both. The standby PCD only talks to the IPSI SIM, and does not communicate with the PKT-INTs. The active server communicates directly with both active and standby PKT-INTs and performs maintenance activities on both PKT-INTs without the standby server getting involved.

There is no dedicated hardware to keep the standby PKT-INT up-to-date. Instead, the PCD refreshes the standby PKT-INT prior to an interchange.

## Executing a PKT-INT Interchange

There are two ways to interchange PKT-INTs, spontaneous and planned.

- 1 A spontaneous interchange is usually caused by a fault, and:
  - Stable calls are retained
  - LAPD links are restarted
  - Some data may be lost
- 1 A planned interchange can be requested by Services' personnel or by software for maintenance or periodic testing.
  - LAPD links are migrated from the active to the standby PKT-INT
  - No data is lost during the interchange

The active server's PCD has socket connections to both active and standby IPSIs. server interchange and IPSI interchange are independent of each other. IPSIs in a PN can be interchanged independently of IPSIs in other PNs.

## Spontaneous PKT-INT Interchange

The standby PKT-INT is not kept up-to-date with the links terminated by the active PKT-INT. During a spontaneous interchange of PKT-INTs, the standby PKT-INT is refreshed with the link information by the active PCD and the standby PKT-INT is activated with a warm reset. A spontaneous interchange of PKT-INTs may result in loss of some up-stream and down-stream data.

- 1 PCD maintains socket connections to the active and the standby PKT-INTs, via the SIM.
- 1 server sends control and data packets only to the active PKT-INT.
- 1 Standby PKT-INT has no information about the LAPD links.
- 1 On a spontaneous interchange, the standby PKT-INT is "refreshed" by the PCD. That means the LAT and the LCT are sent to the PKT-INT, and the standby PKT-INT is made active by a warm interrupt.

## Planned PKT-INT Interchange (Link Migration)

A planned interchange of PKT-INTs uses link migration to assure that no data is lost during the interchange. On a planned interchange of PKT-INTs, software initiates the link migration by sending commands to the active and standby PKT-INTs to make a peer link between the PKT-INTs and to start the link migration process. Down-stream and up-stream messages can be processed by the PKT-INTs during the link migration process. As long as the PKT-INT interchange has not been completed, PCD should continue to send down-stream messages to the active PKT-INT. If a down-stream data packet is for a link that has not yet been migrated over to the standby PKT-INT, the active PKT-INT processes it and sends it out.

If a down-stream data packet is for a link that has already migrated over to the standby PKT-INT, the peer link forwards the down-stream data packet to the standby PKT-INT, and the standby PKT-INT processes it and sends it out. Up-stream messages during migration are handled by both PKT-INTs as with the down-stream messages. The PKT-INT that controls the link (the active PKT-INT if the link has not yet been migrated, and the standby PKT-INT if the link has been migrated) processes the up-stream data packet and sends it up to the PCD. During the migration process, both the active and the standby PKT-INTs can send up-stream messages to the PCD.

On S8700, all down-stream packets go to the active PKT-INT, but the up-stream packets can come from the active and the standby PKT-INTs during the migration process.

- 1 Link migration is performed to prepare the standby PKT-INT for a hot reset.
  - 1 RNRs are not sent to the endpoints at the start of the link migration.
  - 1 PCD tells the active and standby PKT-INTs that a link migration is starting.
  - 1 LAPD links are migrated from the active-mig PKT-INT to the standby-mig PKT-INT in the order they appear in the internal list.
  - 1 Active-mig PKT-INT continues to accept up-stream messages for the links that are not yet migrated. The standby-mig PKT-INT starts accepting up-stream messages for the links that are migrated. Both the active-mig and the standby-mig PKT-INTs send up-stream messages to the PCD.
  - 1 PCD accepts up-stream messages from both the active-mig and standby-mig PKT-INTs.
  - 1 PCD sends every down-stream message to the active-mig PKT-INT and has the active-mig PKT-INT send it out for those links that have not been migrated or forward it to the standby-mig PKT-INT for those links that have been migrated.
  - 1 At the end of the migration, the active-mig PKT-INT tells the PCD that the migration is finished, and PCD tells the standby-mig PKT-INT to go active (hot interrupt). Some coordination verifies that every up- and down-stream message has been flushed from the active-mig PKT-INT before completing the interchange.
- 

---

## **PKT-INT and System Reliability**

---

### **S8700-series IP-PNC**

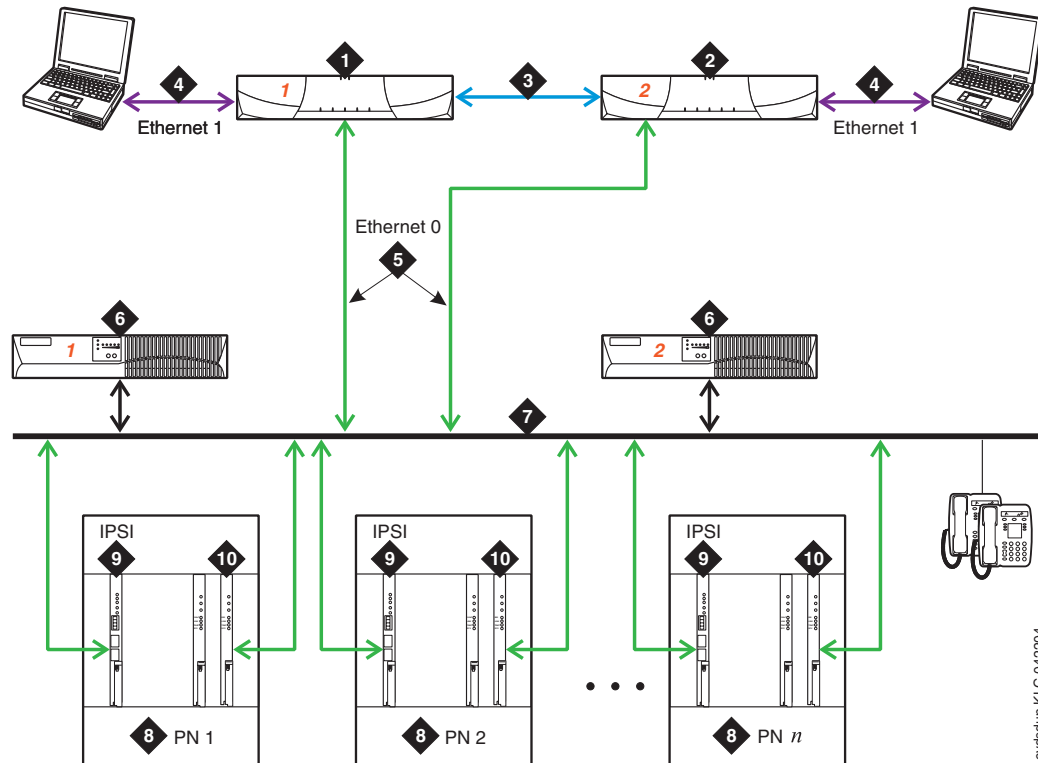

A PKT-INT module resides on each IPSI board. On an S8700 IP-PNC system, there is a duplicated server. One server is in active mode and one server is on standby. The control network(s) may be implemented in a simplex, see [Figure 56: IP-PNC Duplex Reliability - Simplex Control Network](#), or a optional duplicated configuration. There is only one PKT-INT per port network.

**Note:**

Duplicated control networks require G650 media gateways (not G600) because the G600 does not support duplicated clocks. The clock is a component of the TN2312 IPSI.

Figure 56: IP-PNC Duplex Reliability - Simplex Control Network

cydsdup\_KLC\_042204

Figure notes:

1. S8700 Server 1 – two are always present, one in an active mode and one on standby.
2. S8700 Server 2 – two are always present, one in an active mode and one on standby.
3. Duplication Interface – the Ethernet connection between the two S8700 servers.
4. Services Interface – the S8700 servers dedicated Ethernet connection to a laptop. This link is active only during on-site administration or maintenance, and the services interface can link to the non-active server through a Telnet session.
5. Connection from the Servers to the Local Area Network (LAN).
6. UPS units – two required.
7. Local Area Network
8. Port Network – optional configuration of media gateways that provides increased switch capacity.
9. IPSI – provides transport of CCMS messages over IP, allowing the S8700 server to communicate with the port networks.
10. Media Processor - Provides conversion between Time Division Multiplexed (TDM) and Internet Protocol (IP) voice signals.

---

## S8700-series Fiber-PNC

A PKT-INT module resides on each IPSI board. LAPD links are terminated by the PKT-INT modules in the IPSIs that are distributed out to the port networks. The non IPSI connected port networks do not have their own PKT-INT capability, so their LAPD links are terminated by IPSIs in the IPSI connected port networks.

Three items can be duplicated for increased reliability: server, IPSI, and PNC. They can be duplicated independently. Duplicated control networks and duplicated IPSIs go together, so that when the IPSIs are duplicated, the control networks must be duplicated. The set of items in your configuration that are duplicated depend on the reliability option chosen for your system: duplex, high or critical. See [Table 208: Reliability Options](#).

**Table 208: Reliability Options**

| <b>Configurations</b> | <b>Servers</b> | <b>Control Networks and IPSIs</b> | <b>Bearer Networks</b> |
|-----------------------|----------------|-----------------------------------|------------------------|
| Duplex Reliability    | Duplicated     | Unduplicated                      | Unduplicated           |
| High Reliability      | Duplicated     | Duplicated                        | Unduplicated           |
| Critical Reliability  | Duplicated     | Duplicated                        | Duplicated             |

---

## Duplex-Reliability Configuration

The duplex-reliability configuration shown in [Figure 57: Duplex-Reliability Configuration](#) has duplicated servers, an unduplicated control network, unduplicated IPSIs in the IPSI connected PNs, and an unduplicated bearer network. Because the IPSIs are not duplicated, the PKT-INT modules contained within them are not duplicated.

---

**Figure 57: Duplex-Reliability Configuration**

---

## High-Reliability Configuration - Fiber-PNC

The high-reliability configuration shown in [Figure 58: High-Reliability Configuration - Fiber-PNC](#) has duplicated servers, duplicated control networks, and duplicated IPSIs in the IPSI connected PNs. With this configuration, every IPSI connected PN must have duplicated IPSIs. The duplicated control network prevents a single fault in the control network, such as a bad Ethernet switch, from bringing the whole system down. Because the IPSIs are duplicated in this configuration, the PKT-INT modules are duplicated.

---

## High-Reliability Configuration - IP-PNC

The IP-PNC high reliability configuration is similar to the Fiber-PNC configuration. There are no expansion interface circuit packs in the IP-PNC configuration. There are duplicated IPSI circuit packs in each port network. Port networks must use the G650 rack mounted carrier to accommodate the duplicated clock circuits located on the IPSI circuit packs. See [Figure 59: High-Reliability Configuration - IP-PNC](#).

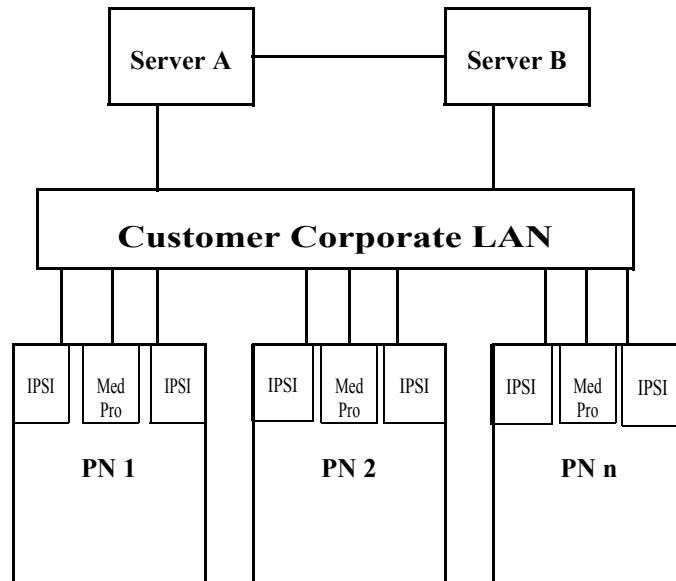

---

**Figure 58: High-Reliability Configuration - Fiber-PNC**

---

**Figure 59: High-Reliability Configuration - IP-PNC**

---

## Critical-Reliability Configuration - Fiber-PNC

The critical-reliability configuration shown in [Figure 60: Critical-Reliability Configuration - Fiber-PNC](#) has full duplication of the following options: servers, control networks, IPSIs and PNCs (bearer networks). As with the high-reliability configuration, this configuration requires that IPSI connected PNs have duplicated IPSIs. Because the IPSIs are duplicated in this configuration, the PKT-INT modules are duplicated.

---

**Figure 60: Critical-Reliability Configuration - Fiber-PNC**

---

## Packet Interface Service Operations

The following sections provide more background information about service operations for the Packet Interface.

## Administration

PKT-INT modules are automatically administered as a component of an IPSI circuit pack. See `add/remove ipserver-interface` and `test/status/reset packet-interface` in *Maintenance Commands Reference (03-300431)*.

## Packet Interface Circuit Replacement

To replace a Packet Interface module that is part of a TN2312AP IPSI circuit pack, follow the procedure for replacing an IPSI circuit pack.

## Demand Reset of a Packet Interface

System software denies a demand reset of an active IPSI's Packet Interface (`reset packet-interface`) if the Packet Interface is in service and has not been placed in an out-of-service state by background maintenance software. A reset of an in-service Packet Interface causes severe service disruption, including the loss of all existing calls, and dropped links to adjuncts such as AUDIX. As part of the automatic recovery action initiated when a fatal hardware-fault condition is detected, the software that controls Packet Interface maintenance puts a Packet Interface module in the out-of-service state if that IPSI circuit pack has been reset three times within the last 15 minutes.

A demand reset of a standby Packet Interface is not disruptive and is allowed regardless of the service state of the associated maintenance software.

## Service States

Packet Interface maintenance software maintains a state variable to monitor the service state of each Packet Interface. To determine the state of a Packet Interface, use `status packet-interface`. A Packet Interface can be in the service states:

- 1 *in-service* - in service and active
- 1 *standby* - in service and standby
- 1 *out-of-service* - active or standby Packet Interface not in service
- 1 *standby-disabled* - IPSI circuit pack with Packet Interface module is present and administered, but duplication is disabled
- 1 *craft-busy* - Packet Interface has been demand busied out by craft
- 1 *uninstalled* - Packet Interface is administered but not physically present

---

**S8700 | S8710 | S8720**

If the circuit pack's diagnostic tests do not pass in a standard- or duplex-reliability system (unduplicated IPSIs), the failing Packet Interface is placed in an out-of-service state. Every link handled by that IPSI goes down, and may be re-established using other Packet Interface resources. Calls associated with these links may drop.

If the standby IPSI (in a high- or critical-reliability system with duplicated IPSIs) has an acceptable state of health, maintenance software interchanges the IPSIs, instead of resetting the active IPSI's Packet Interface module. This is less disruptive than a reset.

---

An IPSI's Packet Interface module goes out-of-service if the IPSI has been reset by background maintenance 3 times in the last 15 minutes, whether or not reset succeeded. Various errors will lead to a Packet Interface reset. See the [Error log entries and recommended actions](#) section.

An extensive set of diagnostic tests is run when the circuit pack is reset.

---

**S8700 | S8710 | S8720**

## Duplication Impact

The Packet Interface module is a single point of failure in a standard- or duplex-reliability system, with unduplicated IPSIs. If not acceptable, an S8700 customer can upgrade to a high- or critical-reliability system with duplicated IPSIs. [Figure 55: Distributed PKT-INTs](#) shows an S8700 Fiber-PNC configuration with duplicated IPSIs. The following concepts apply to duplicated IPSIs:

- 1 Packet bus connection

In a high- or critical-reliability system (duplicated IPSIs), the standby IPSI's Packet Interface module cannot access the packet bus to write data, except during a planned IPSI interchange or when the [Active-Standby Peer Link Test \(#888\)](#) is run. The [Packet Interface Maintenance Looparound Test \(#886\)](#), which requires access to the packet bus, is not run on the standby IPSI's Packet Interface module.

- 1 IPSI interchange

Severe Packet Interface module faults that cause system and application links to go down are detected within 1 second. A fatal fault error message is generated, and the Packet Interface maintenance software attempts to run the Packet Interface Reset test. In a high- or critical-reliability system, this results in a requested IPSI interchange, instead of a Packet Interface reset, since stable calls are preserved across the interchange.

---

## Maintenance Object Interactions

### 1 Packet Bus maintenance

A Packet Interface physically interacts with the PKT-BUS. It may be difficult to isolate faults to one or the other component for certain types of Packet Interface errors. In each of these cases, Packet Interface maintenance forwards an error report to packet bus maintenance, where it records a packet bus fault in the error log and runs Packet Bus tests.

### 1 Packet Interface maintenance

The operation of the IPSI circuit pack's Packet Interface module affects the operation and maintenance of other circuit packs connected to the packet bus. This includes:

1. BRI applications (BRI-PT)
2. Universal DS1 applications (UDS1) for ISDN/PRI applications
3. **S8700-series Fiber-PNC**: Expansion Interface circuit pack maintenance (EXP-INTF)

Some packet errors require examination of the Packet Interface's operating status. To obtain this information:

- 1 Examine the Error and Alarm Logs for PKT-INT entries and determine which PKT-INT the link is accessing.
- 1 Use `status sys-link` to identify the PKT-INT location in this PN, or use `status sys-link` to find the PKT-INT hardware used by the faulted link.
- 1 Use `test sys-link` to troubleshoot the component.
- 1 Use `status packet-interface` to determine the:
  - service state of the Packet Interface, for example, in service/out of service
  - total number of Packet Interface links assigned to a Packet Interface.

For a standby IPSI's Packet Interface module in a high- or critical-reliability system (duplicated IPSIs), the module is shown in standby mode if it is not out-of-service because of a failure condition. The number of links for a standby Packet Interface module is always zero.

In general, if every link for an active IPSI's Packet Interface module is shown as a Failed Link, there may be a fault on either the Packet Interface module or the packet bus that caused every link to go down. If only a small percentage of the links are shown as Failed Links, then the Packet Interface is probably not the source of the problem. Some typical sources of individual link failures include:

- 1 failed BRI telephone set
- 1 disconnected cord to a BRI set, causes three link failures
- 1 **S8700-series Fiber-PNC**: failed or removed EI circuit pack in a PN, causes one link failure

For a case where not every link appears in the Failed Links category, examine the alarm and error logs for failures of the following circuit packs, and follow the repair procedures for those circuit packs before considering replacing the associated IPSI circuit pack:

- | **S8700-series Fiber-PNC**: TN570 Expansion Interface circuit pack (EXP-INTF)
- | **S8700-series Fiber-PNC**: TN573 Switch Node Interface circuit pack (SNI-BD)
- | **S8700-series Fiber-PNC**: TN572 Switch Node Clock circuit pack (SNC-BD)
- | **S8700-series Fiber-PNC**: TN2305, TN2306 ATM
- | ISDN-BRI Line circuit packs, ports, and stations (BRI-BD, BRI-PORT, BRI-SET)
- | Universal DS1 circuit packs and ports (UDS1-BD, TIE-DS1)
- | TN464, TN2207, TN2464 Universal DS1 circuit pack — ISDN-PRI service
- | TN556, TN2198, TN2185 ISDN-BRI Line circuit pack — ISDN-BRI service
- | TN799DP Control LAN (C-LAN) circuit pack
- | TN2501 Voice Announcements over the LAN (VAL)
- | TN2602 IP Media Processor (IPMEDPRO)

Use `test sys-link` with the faulted path option to test all components in the faulted link.

## Error log entries and recommended actions

Table 209: PKT-INT Error Log Entries 1 of 2

| Error Type     | Aux Data | Associated Test                    | Alarm Level | On/Off Board | Recommended Action                                       |
|----------------|----------|------------------------------------|-------------|--------------|----------------------------------------------------------|
| 0 (a)          | 0        | Any                                | Any         | ON           | <code>test packet-interface location 1 r 2</code>        |
| 1 (b)          | Any      |                                    | WARNING     | OFF          | <code>reset packet-interface location<sup>1</sup></code> |
| 10 (c)         | 0        |                                    |             |              |                                                          |
| 50 (d)         | 0        |                                    |             |              |                                                          |
| 257 (e)        | Any      |                                    | MIN         | OFF          | <code>reset packet-interface location</code>             |
| 513 (f)        | Any      |                                    | MAJ         | ON           | <code>reset packet-interface location</code>             |

| 1793 (k)                 | Any      | Memory Checksum (#884)          | MIN         | ON           | <code>test packet-interface location l r 2</code>        |
| 2049 (l)                 | Any      |                                 | WRN         | ON           | <code>test packet-interface location r 25</code>         |
| 2305 (m)                 | Any      |                                 |             |              | <code>test packet-interface location r 2</code>          |
| 2561 (n)                 | Any      | Active-Standby Peer Link (#888) | MIN         | OFF          | <code>test packet-interface location r 2</code>          |
| 2817 (o)                 | Any      | Read and Clear test (#887)      | MIN<br>MAJ  | ON           | <code>test packet-interface location</code>              |
| 3074<br>3073<br>3072 (p) | Any      | Maintenance Looparound (#886)   | WRN         | OFF          | <code>test packet-interface location r 2</code>          |
| 3585 (q)                 | Any      |                                 | WRN         | OFF          | <code>reset packet-interface location<sup>1</sup></code> |
| 3841 (r)                 | Any      |                                 | MAJ         | OFF          | <code>reset packet-interface location<sup>1</sup></code> |
|                          |          |                                 |             |              | <b>2 of 2</b>                                            |

1. You can reset a Packet Interface module on an active IPSI if it has been taken out of service by the background maintenance software. A Packet Interface module on a standby IPSI can be reset independent of its service state.

Notes:

- a. **Error Type 0:** an alarm was raised but an associated error was not entered into the error log due to a momentary overload condition caused by a burst of hardware or software error reports. Run the long test sequence. Refer to the test description and follow the recommended procedures.
- b. **Error Type 1:** background maintenance software has reset the Packet Interface module on an IPSI circuit pack as a fault recovery action. It is used to keep track of the number of times that the Packet Interface is reset, independent of whether or not the Reset test passed. When 3 of these errors occur in 15 minutes, maintenance places the Packet Interface into

an out-of-service state, and raises a WARNING off-board alarm on the Packet Interface (PKT-INT).

1. See if Error Codes 257, 513, 769, 1025, 1281, or 3841 are present in the error log. If one or more are present, follow the repair procedures for those errors.
  2. If no other Packet Interface errors appear in the error log, and if the Packet Interface is not in a held reset state as indicated by the absence of a MAJOR or MINOR alarm with a Service State of OUT, you do not have to take any action. If a Packet Interface MAJOR or MINOR alarm is present and no other Packet Interface Error Codes are in the error log, use reset packet-interface location to execute a demand reset, and refer to the repair procedures for [Packet Interface Reset Test \(#889\)](#).
- c. **Error Type 10:** the Packet Interface maintenance software caused an escalating system WARM restart as part of a recovery action for certain Packet Interface failures. A present SYSTEM Error Type 10 indicates that a software-initiated WARM restart occurred.
1. See if Error Types 513, 1025, or 3074 are present in the error log. If any are present, follow the repair procedures for those errors.
- d. **Error Type 50:** the server is sending more downlink messages than the Packet Interface module can process. This is an inline error not produced by any test. When this error is reported, application software is slowed down to allow the module to process existing downlink messages. If there is a hardware problem, the Packet Interface test causes other errors to be logged. In rare cases when no other PKT-INT errors are logged but error 50 occurs more than 10 times in the last hour, follow normal escalation procedures.
- e. **Error Type 257:** the Packet Interface module on the IPSI circuit pack detected a fatal failure. This error is very serious. Maintenance software immediately escalates testing to the [Packet Interface Reset Test \(#889\)](#). This error can be caused by network connectivity loss between the Server and the IPSI where the packet interface Module resides.
1. If the Packet Interface module has a WARNING alarm: the alarm is caused by the connectivity loss between the server and the IPSI.
  2. If the Packet Interface module has a MINOR alarm: verify the network reachability of IPSI from the server.
    1. If the network is out: try to restore the network connectivity.
    1. If connected to IPSI: use the reset packet-interface location to reset the Packet Interface. Refer to the repair procedures for the [Packet Interface Reset Test \(#889\)](#).
  3. If the Packet Interface is not alarmed: you do not have to take any action.
- f. **Error Type 513:** Message Handshake failure. A failure with the message protocol between the server's software and the Packet Interface was detected.
1. If the Packet Interface has a MAJOR alarm:
    - a. Use `reset packet-interface location` to reset the Packet Interface.
    - b. Refer to the repair procedures for the [Packet Interface Reset Test \(#889\)](#).

2. If the Packet Interface is not alarmed, take no action.
- g. **Error Type 769 and 770:** failure in the Packet Looparound test. A maintenance looparound link cannot be established or the Packet Interface cannot send and receive data correctly as part of the [Packet Interface Maintenance Looparound Test \(#886\)](#). If the number of errors exceeds a defined threshold, a Major alarm is raised.
- In a high- or critical-reliability system (duplicated IPSIs), a failure of the Maintenance Looparound test may have caused an IPSI interchange. This results in an alarm associated with Error Code 769 or 770 being reported against the standby IPSI's Packet Interface module.
- Test 886 can be run only on the active IPSI. Enter `busy ipserver-interface` followed by `release ipserver-interface` to clear the error on the standby IPSI. Then enter `set ipserver-interface` to force an IPSI interchange.
- Error code 770 indicates that old firmware on the IPSI does not support new software operation.
- For more information, refer to the repair procedures of the [Packet Interface Maintenance Looparound Test \(#886\)](#).
- h. **Error Type 1025:** failure of the [Packet Interface Private Looparound Test \(#885\)](#).
1. If the Packet Interface has a MAJOR alarm:
    - a. Use `reset packet-interface location` to reset the Packet Interface.
    - b. Refer to the repair procedures for [Packet Interface Reset Test \(#889\)](#).
  2. If the Packet Interface is not alarmed, take no action.
- i. **Error Type 1281:** the Packet Interface has Translation RAM failures. PKT-INT Translation RAM is used to convert the addresses of a packet to the destination endpoint address.
1. If the Packet Interface has a MAJOR alarm:
    - a. Use `reset packet-interface location` to reset the Packet Interface.
    - b. Refer to the repair procedures for the [Packet Interface Reset Test \(#889\)](#).
  2. If the Packet Interface is not alarmed, take no action.
- j. **Error Type 1537:** Boot PROM memory failure. The Packet Interface module may still be operational if no other errors are reported. However, the module may report a fatal fault during board initialization. This may occur during a system recovery level more severe than a WARM restart. For more information, refer to [Packet Interface Memory Checksum Test \(#884\)](#).
- k. **Error Type 1793:** FLASH Memory test failure. The Packet Interface module may still be operational if no other errors are reported. However, the module may report a fatal fault during board initialization. This may occur during a system recovery level more severe than a WARM restart. For more information, refer to the repair procedures of [Packet Interface Memory Checksum Test \(#884\)](#).

- l. **Error Type 2049:** LAPD Received Buffer Overflow error. The Packet Interface's packet bus receive buffer overflowed. For more information, refer to the repair procedures of [Packet Interface Read and Clear Counters \(#887\)](#).
- m. **Error Type 2305:** parity failure was detected by the packet bus interface. The Packet Interface received packets with parity errors from the packet bus.
  1. Check for errors logged against the packet bus and Maintenance/ Test circuit pack. Refer to repair procedures to clear those errors first.
  2. Check every other circuit pack connected to the packet bus in the same cabinet. Packet bus failures may be caused by a faulty circuit pack connected to the backplane or bent pins on the back plane.
  3. If the problem still exists, use `test packet-interface`, and follow repair procedures described for [Packet Interface Read and Clear Counters \(#887\)](#).
- n. **Error Type 2561:** Active-Standby Peer Link test failure indicating a possible failure of the:
  - 1 Active IPSI's Packet Interface
  - 1 Standby IPSI's Packet Interface

If the number of errors exceeds a defined threshold, a Minor alarm is raised. For more information, refer to the repair procedures of [Active-Standby Peer Link Test \(#888\)](#).
- o. **Error Type 2817:** Standby Packet Interface Translation RAM failure. A MINOR alarm is raised when there are 1 to 5 bad locations and a MAJOR alarm is raised when there are 5 or more bad locations. Use `test packet-interface`, and follow repair procedures described for [Packet Interface Read and Clear Counters \(#887\)](#).
- p. **Error Types 3074, 3073, and 3072:** PKT-INT Transmit Buffer Overflow, the number of transmit buffers required by software exceeded the number available. **Error Type 3074** is generated when the PKINT sends an inline hardware error to maintenance software, indicating transmit buffer overflow. As part of the background recovery action for this error, maintenance software automatically runs the [Packet Interface Maintenance Looparound Test \(#886\)](#). If that test fails, maintenance software generates **Error Types 3073 and 3072**, and it requests a system WARM restart. If, after the WARM restart, transmit buffer overflow errors continue to be reported, maintenance software generates Error Code 100 and it resets the PKT-INT. These errors may be the result of system overload due to a problem with communication between the PKT-INT and the PNs.
  1. Check for errors logged against the Expansion Interface circuit pack, the Switch Node Interface circuit pack, Packet Gateway circuit pack, the Packet Data Line circuit packs associated with the System Ports, BRI Line circuit packs and BRI endpoints, and the Universal DS1 circuit packs supporting PRI service. Clear errors against those components first.
  2. Use `test packet-interface short` against the Packet Interface associated with the error. If the [Packet Interface Maintenance Looparound Test \(#886\)](#) passes, the alarm will clear. If the test fails, repeat the test 5 times.
  3. If it continues to fail, follow normal escalation procedures.

- q. **Error Type 3585:** a packet bus failure has been detected and that the packet bus is alarmed. Refer to the packet bus maintenance documentation for further action.
- r. **Error Type 3841:** the Packet Interface reported a fatal fault failure condition that might be caused by a packet bus fault on the PN containing the failed PKT-INT.
  - 1. If Error Type 3585 has also been reported, see [PKT-BUS \(Packet Bus\)](#). After the packet bus fault has been corrected, use `reset packet-interface` to bring the Packet Interface back into service.
  - 1. If Error Type has not been reported, use `reset packet-interface`, and follow the repair steps associated with [Packet Interface Reset Test \(#889\)](#)

---

## Demand test descriptions and error codes

Investigate tests in the order presented. By clearing errors associated with the first test, errors generated from other tests may also be cleared. Click on the link to see the full description of the test, error codes, and recommended actions.

| Order of Investigation                                                     | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|----------------------------------------------------------------------------|---------------------|--------------------|-------------------|
| <a href="#">Packet Interface Private Looparound Test (#885)</a>            |                     | X                  | ND                |
| <a href="#">Packet Interface Maintenance Looparound Test (#886)</a>        | X                   | X                  | ND                |
| <a href="#">Packet Interface Memory Checksum Test (#884)</a>               |                     | X                  | ND                |
| <a href="#">Packet Interface Read and Clear Counters (#887)</a>            | X                   | X                  | ND                |
| <a href="#">Active-Standby Peer Link Test (#888)</a>                       | X                   | X                  | ND                |
| The following test is run as a result of <code>reset board location</code> |                     |                    |                   |
| <a href="#">Packet Interface Reset Test (#889)</a>                         |                     |                    | D                 |

1. D = Destructive; ND = Nondestructive

## PLAT-ALM (Platform Alarms)

The PLAT-ALM is a virtual MO used by Communication Manager to keep track of its server and media gateway alarms.

**Note:**

“CMG” can be seen in some media gateway traps.

If there is an alarm against PLAT-ALM, do the following:

1. Access the server's Linux command line by entering the SAT command `go shell`.
2. Log into the server's Linux shell.
3. View the server's current list of alarms by entering `almdisplay -v`.  
See *Avaya Aura™ Communication Manager Server Alarms (03-602798)*.

**Note:**

If the `almdisplay` command returns a failure message, such as:

**almdisplay: 4: Unable to connect to Multifilament**

enter `man almdisplay` for command-related information.

4. Troubleshoot and clear the problems by following the procedures for the maintenance object listed under either:
  - *Avaya Aura™ Communication Manager Server Alarms (03-602798)*
  - *Gateway Traps for the G250/G350/G430/G450/G700 Avaya S8xxxx Servers (03-602803)*

An alternative procedure for an alarm against PLAT-ALM requires the following steps:

1. Log into the server's Web interface.
2. View the server's current list of alarms by clicking on the **Display Alarms** option.
3. Troubleshoot and clear the problems by following the procedures for the appropriate MOs listed in the display.

**Note:**

After repairing the server or media gateway, use the Linux command `almclear` to manually clear every server or media gateway alarm. This action will also clear any alarms associated with PLAT-ALM. See *Clearing Server Alarms in Avaya Aura™ Communication Manager Server Alarms (03-602798)*.

---

## Demand test descriptions and error codes

There are no demand tests for PLAT-ALM.

## PMS-LINK (Property Management System Link)

| MO Name in Log | Alarm Level | Initial Command to Run          | Full Name of MO |
|----------------|-------------|---------------------------------|-----------------|
| PMS-LINK       | MIN         | <code>test pms-link long</code> | PMS Link        |
|                | WRN         | <code>test pms-link</code>      |                 |

Property Management System (PMS) is a stand-alone computer system that environments such as hotels or hospitals use for services such as reservations, registration, messaging, housekeeping, night audit, billing, and inventory. The PMS Link provides a communications channel between the switch and the customer-owned PMS so that the PMS can interrogate the system for information related to the following features:

- 1 Message Waiting Notification
- 1 Controlled Restriction
- 1 Housekeeping Status
- 1 Check-in/Check-out
- 1 Room Change/Room Swap

The PMS device connects to the system via a data module (PDM, MPDM, DTD) connected to a port on a TN754 Digital Line circuit pack which is administered as a data extension. The PMS link to the processor is via a TN799 C-LAN port. For information about C-LAN connectivity, refer to [CLAN-BD \(Control LAN Circuit Pack\)](#).

PMS Link maintenance provides a strategy for maintaining the link between the switch and a PMS device. The strategy includes a set of tests for periodic diagnosis, detection of errors during normal operation, actions for troubleshooting, and raising alarms for serious problems. PMS Link Maintenance uses a “try-and-wait” mechanism for maintaining the PMS Link. If a PMS Link is torn down due to an error, PMS Link Maintenance attempts to bring up the link immediately. If the Link Setup fails, PMS Link Maintenance will wait for five minutes before the next retry. If the number of retries reaches a threshold (12), a Minor alarm is raised for service attention.

PMS Link Maintenance does not cover the maintenance of the elements composing the PMS physical link (the external PMS device, Data Module (PDM/MPDM/DTDM), Digital Line Port of a TN754 Digital Line circuit pack, ADU, or Data Line Port of TN726B Data Line circuit pack). If PMS Link Maintenance cannot restore the PMS Link, then the maintenance tests of these individual components of the PMS Link must be executed to diagnose faults. If `test pms-link` fails, no alarm will be generated.

The `list pms-down` command lists every meaningful event to the PMS that occurred while the link between the switch and the PMS was down. For example, any room status codes entered by hotel housekeeping staff during a time of PMS outage would be shown in this report.

## Procedures for Restoring the PMS Link

1. Determine the status of the PMS Link.

Enter `status pms-link`, and make sure that the PMS Link is not busied out for maintenance. If the link is “down,” then continue with the next step.

2. Where does the PMS Link connect?

Enter `display system-parameters hospitality`, and find out the destinations of the PMS Link.

3. Determine the status of the data extension.

Enter `status data extension`, and verify whether the data extension is in the in-service/idle state. If the data extension is not available, then look for the extension number in Alt Name field of the Error Log. See [XXX-BD \(Common Port Circuit Pack/Media Module\)](#) for resolutions.

4. Is the external PMS device available?

Make sure that the PMS device is ON-LINE and ready for service. Check the physical connectivity between Data Module and the PMS device.

5. If the problem is not found in the above steps, check the C-LAN board for any problems. For a description about the C-LAN board and its connectivity, refer to Downloading License and Authentication files from RFA in *Maintenance Procedures (03-300432)*.

When restoring the PMS link, it is necessary to execute maintenance test on different objects that comprise the PMS link. It is recommended that you busyout the PMS link before trying to restore the link. When the PMS Link is busied out, every PMS Link maintenance action is deactivated, and interference with tests of other MOs is prevented.

---

## Error log entries and recommended actions

Table 210: PMS-LINK Error Log Entries 1 of 2

| Error Type | Aux Data | Associated Test               | Alarm Level          | On/Off Board | Recommended Action            |
|------------|----------|-------------------------------|----------------------|--------------|-------------------------------|
| 0 (a)      | 0        | Any                           | Any                  | Any          | <code>test pms-link</code>    |
| 18 (b)     | 0        | <code>busyout pms-link</code> | WRN                  | OFF          | <code>release pms-link</code> |
| 257 (c)    | Any      | Link Retry test (#215)        | MIN WRN <sup>1</sup> | OFF          | <code>test pms-link 1</code>  |
| 513 (d)    | Any      |                               |                      |              | <code>test pms-link</code>    |
| 769 (e)    | Any      |                               |                      |              |                               |
|            |          |                               |                      |              | <i>1 of 2</i>                 |

**Table 210: PMS-LINK Error Log Entries 2 of 2**

| Error Type | Aux Data                      | Associated Test | Alarm Level | On/Off Board | Recommended Action                                  |
|------------|-------------------------------|-----------------|-------------|--------------|-----------------------------------------------------|
| 1025 (f)   | 40–49                         |                 |             |              |                                                     |
| 1281 (g)   | 10–19                         |                 |             |              |                                                     |
| 1537 (h)   | N0–N9                         |                 |             |              |                                                     |
| 1793 (i)   | Any                           |                 |             |              | <code>test pms-link</code>                          |
| 2049 (j)   | Any                           |                 |             |              |                                                     |
| 2305 (k)   | 50–59                         |                 |             |              | <code>release pms-link, or<br/>test pms-link</code> |
| 2561 (l)   | Any                           |                 |             |              | <code>test pms-link</code>                          |
| 2817 (m)   | 100–109<br>200–209<br>300–309 |                 |             |              |                                                     |
| 3073 (n)   | 70–79                         |                 |             |              |                                                     |
| 3841 (o)   | 20–29                         |                 |             |              |                                                     |
|            |                               |                 |             |              | <b>2 of 2</b>                                       |

1. Minor alarms on this MO may be down graded to Warning alarms based on the value in `set options`.

Notes:

- a. **Error Type 0:** run the short test sequence first. If every test passes, run the long test sequence. Refer to each test's description, and follow its procedures.
- b. **Error Type 18:** the PMS Link has been busied out with `busyout pms-link`. The link is torn down. Enter `release pms-link` to restore the link.
- c. **Error Type 257:** the Link Retry test (#215) fails. An error was detected when setting up the link. Refer to the [Procedures for Restoring the PMS Link](#) above.
- d. **Error Type 513:** the PMS physical link is down for one of the following reasons:
  - 1 Cable to the PMS device is disconnected.
  - 1 The PMS device is powered off.
  - 1 The data extension to which the PMS device connects has been busied out.

Check the connectivity of wire and cable among wall jacket, data module, and the PMS device. Enter `status data extension` and verify that the data extension of the PMS device is in the in-service/idle state. If the data extension is not available, then see [Procedures for Restoring the PMS Link](#).

- e. **Error Type 769:** there has been no communication between the switch and the PMS for a period of time specified in “system hospitality” administration. The PMS Link is torn down. To clear this error, see [Procedures for Restoring the PMS Link](#).
- f. **Error Type 1025:** The link was taken down because the switch could not receive an incoming message from the PMS. The message from the PMS repeatedly had corrupted data or the switch received requests for acknowledgment but never received a message to be processed. If this Error Type occurs frequently (more than once a month), advise the customer to call the vendor of the PMS to check out the PMS device. Once the PMS Link is successfully established, this error disappears from the Error Log.
- g. **Error Type 1281:** the link was taken down because the switch could not send an outgoing message. The message, which was sent but not acknowledged, was flushed. If this Error Type occurs frequently (more than once a month), advise the customer to call the vendor of the PMS to check out the PMS device. Once the PMS Link is successfully established, this error disappears from the Error Log.
- h. **Error Type 1537:** the PMS has been busied out for maintenance at the request of the PMS. The PMS Link is torn down. The reason code (N), if present, is that supplied by the PMS in the request message. If this Error Type recurs frequently (that is, more than once a month), advise the customer to call the vendor of the PMS to check out the PMS device. Once the PMS Link is successfully established, this error disappears from the Error Log. No alarm is raised against this error.
- i. **Error Type 1793:** due to heavy call traffic, or the PMS protocol message rate being faster than the PMS/PBX protocol specifications allow, the PMS Link is torn down. PMS Link maintenance software will wait for five minutes before attempting to set up the link again. If this Error Type occurs frequently (more than once a month), advise the customer to call the vendor of the PMS to check out the PMS device. Once the PMS Link is successfully established, this error disappears from the Error Log. The PMS should be checked for adherence to message rate defined in the PMS/PBX protocol specifications. No alarm is raised against this error.
- j. **Error Type 2049:** The attempt to swap the database between PBX and PMS failed three times consecutively due to excessive PMS/PBX protocol violations, buffer overflows, or PMS Link outages. The PMS Link is NOT torn down. If this Error Type occurs frequently (more than once a month), advise the customer to call the vendor of the PMS to check out the PMS device. Once the PMS Link is successfully established, this error disappears from the Error Log. No alarm is raised against this error.
- k. **Error Type 2305:** The PMS Link was busied out with `busyout pms-link`, or it was brought down with `test pms-link long`. The PMS Link is torn down, and PMS Link maintenance stops attempts to reestablish the link in the case where the `busyout pms-link` was used. When `test pms-link long` has been used, PMS Link maintenance continues trying to reset the link. To restore the PMS Link after use a `busyout pms-link`, enter `release pms-link`. To restore the PMS Link after a `test pms-link long`, enter `test pms-link`.

i. **Error Type 2561:** the PMS Link is physically established, but the protocol has not been started by the PMS before the protocol timer expires. The PMS Link is NOT torn down. If this Error Type occurs frequently (more than once a month), advise the customer to call the vendor of the PMS to check out the PMS device. Once the PMS Link is successfully established, this error disappears from the Error Log. The PMS should be checked to make sure that it will attempt to start the protocol according to the PMS/PBX protocol specifications. No alarm is raised against this error.

m. **Error Type 2817:** look for the following Aux Data:

|     |                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
|-----|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 10x | The PMS violated the application protocol. The first message after a request to initiate a database exchange was not the start of a database exchange. The message is processed. If this Error Type with this aux data value occurs frequently (more than once a month), advise the customer to call the vendor of the PMS to check out the PMS device. Once the PMS Link is successfully established, this error disappears from the Error Log.        |
| 20x | The PMS violated the application protocol. The start of a database exchange was received in a state in which it was not expected. The message is ignored. If this Error Type with this Aux data value occurs frequently (more than once a month), advise the customer to call the vendor of the PMS to check out the PMS device. Once the PMS Link is successfully established, this error disappears from the Error Log.                               |
| 30x | The PMS violated the application protocol. The end of a database exchange was received when no exchange was in progress. The message is ignored. If this Error Type with this Aux Data value occurs frequently (more than once a month), advise the customer to call the vendor of the PMS to check out the PMS device. Once the PMS Link is successfully established, this error disappears from the Error Log. No alarm is raised against this error. |

The PMS should be assessed for adherence to the PMS/PBX protocol specifications.

- n. **Error Type 3073:** the link was taken down by the switch because the threshold for application protocol violations has been exceeded by the PMS. The protocol never started and messages were received and/or messages were received in a state in which they were not expected. (Refer to Error Type 2817 for recommended strategy.)
- o. **Error Type 3841:** link was taken down by the switch because the threshold for link protocol violations has been exceeded by the PMS. PMS is sending “garbage” to the switch.

---

## Demand test descriptions and error codes

Investigate tests in the order presented. By clearing errors associated with the first test, errors generated from other tests may also be cleared. Click on the link to see the full description of the test, error codes, and recommended actions.

| Order of Investigation                     | Short Test Sequence | Long Test Sequence | D/ND           |
|--------------------------------------------|---------------------|--------------------|----------------|
| <a href="#">Link Tear Down Test (#213)</a> |                     | X                  | Destructive    |
| <a href="#">Link Retry Test (#215)</a>     | X                   | X                  | Nondestructive |

## PMS-PRNT (PMS Printer Link)

| MO Name in Log       | Alarm Level | Initial Command to Run                                    | Full Name of MO                 |
|----------------------|-------------|-----------------------------------------------------------|---------------------------------|
| PMS-PRNT<br>JNL-PRNT | MIN         | <code>test journal [pms-log  <br/>wakeup-log] long</code> | PMS Printer/<br>Journal Printer |
|                      | WRN         | <code>test journal [pms-log  <br/>wakeup-log]</code>      |                                 |

The errors and tests for PMS-PRNT also apply to JNL-PRNT.

A journal printer is a printer to which Emergency Access to Attendant, Wakeup and Property Management System (PMS) events are printed as they occur. The PMS-log printer is used as a backup of the PMS output device to print an audit trail of every PMS transaction and Housekeeping Status Change event when the PMS Printer Link is not available. There may be one or two journal printers. If there is one, every event is printed there. If there are 2, then emergency access, wakeup events, and scheduled reports are printed at one printer (JNL-PRNT), and PMS events are printed at the other (PMS-PRNT).

The scheduled report printer is where summaries of daily wakeup activity and emergency access activity are printed. If the customer requests a summary report, the report will be printed exactly once per day.

The distinction between Journal and Scheduled report printers is logical rather than physical. Whether or not there are two printers, the scheduled reports are always sent to the printer that journals the wakeup and emergency access events. A scheduled report will temporarily suspend the journal activity. Upon completion of the scheduled report, journaling will be resumed after the printing of every withheld event.

The journal printer device connects to the system via a data module (PDM, MPDM, DTDM) connected to a port on a TN754 Digital Line circuit pack that is administered as a data extension. A journal printer device can also be connected through an ADU to a port on TN726B Data Line circuit pack. The journal printer's link to the processor is via a C-LAN port. For information about C-LAN connectivity, see [CLAN-BD \(Control LAN Circuit Pack\)](#).

PMS/JOURNAL Printer Link Maintenance provides a strategy for maintaining the link between the system and a PMS device (an external Journal Printer device). The strategy includes a set of tests for periodic diagnosis, detection of errors during normal operation, actions for troubleshooting, and raising alarms for serious problems. PMS Printer Link Maintenance uses a try-and-wait mechanism. If a PMS Printer Link is torn down due to an error, PMS Printer Link Maintenance will try to bring the link up immediately. If the link setup fails, PMS Link Maintenance will wait for five minutes before the next trial. If the number of retries reaches a threshold (15), a Minor alarm is raised for service attention.

PMS Printer Link Maintenance does not cover the maintenance of the elements composing the journal printer physical link (for instance, the external printer device, Data Module (PDM/MPDM/DTDM), Digital Line Port or ADU and Data Line Port). If PMS Printer Link maintenance cannot restore the PMS Printer Link, then the maintenance tests of individual components of the PMS Link must be executed to diagnose faults.

The `list pms-down` command lists every meaningful event to the PMS that occurred while the link between the switch and the PMS was down. For example, any room status codes entered by hotel housekeeping staff during a time of PMS outage would be reflected in this report.

### Procedures for Restoring the PMS Printer Link

1. Determine the status of the PMS Printer Link.

Enter `status journal-printer wakeup-log | pms-log` and make sure that the journal printer link is not busied out for maintenance. If the link is down, then continue to the next step.

2. Where does the journal printer link connect?

Enter `display system-parameters hospitality` and find out the destinations of the PMS Printer Link.

3. Determine the status of the data extension.

Enter `status data extension` and verify that the data extension is in the in-service/ idle state. If the data extension is *not* available, look for the extension number in the **Alt Name** field of the Error Log. See [XXX-BD \(Common Port Circuit Pack/Media Module\)](#) for resolutions.

4. Is the external printer device available?

Make sure that the printer device is ON-LINE and ready for service. Check the physical connectivity between Data Module and the printer device.

5. If the problem is not found in the above steps, check the C-LAN board for any problems. For a description of C-LAN connectivity, see [CLAN-BD \(Control LAN Circuit Pack\)](#).

It should be noted that when restoring the PMS printer link, it is necessary to execute tests on different MOs that comprise the link; it is recommended that you busyout the PMS printer link before trying to restore the link. If the PMS printer Link is busied out, then every PMS printer Link maintenance action is deactivated, and interference with tests of other MOs is prevented.

## Error log entries and recommended actions

Table 211: PMS-PRNT/JNL-PRNT Error Log Entries

| Error Type | Aux Data | Associated Test                                   | Alarm Level             | On/Off Board | Recommended Action                                  |
|------------|----------|---------------------------------------------------|-------------------------|--------------|-----------------------------------------------------|
| 0 (a)      | 0        | Any                                               | Any                     | Any          | <code>test journal wakeup-log   pms-log</code>      |
| 18 (b)     | 0        | <code>busyout journal wakeup-log   pms-log</code> | WRN                     | OFF          | <code>release journal wakeup-log   pms-log</code>   |
| 257 (c)    | Any      | Link Retry test (#215)                            | MIN <sup>1</sup><br>WRN | OFF          | <code>test journal wakeup-log   pms-log long</code> |
| 513 (d)    | Any      |                                                   |                         |              | <code>test journal wakeup-log   pms-log</code>      |
| 769 (e)    |          |                                                   |                         |              |                                                     |

1. Minor alarms may be downgraded to Warning alarms based on the value used in `set options`.

### Notes:

- a. **Error Type 0:** run the short test sequence first. If every test passes, run the long test sequence. Refer to each test's description and follow its procedures. Both PMS Printer and Journal Printer are administered to the same extension, and the printer is not connected. Refer to the [Procedures for Restoring the PMS Printer Link](#) for resolution.
- b. **Error Type 18:** the Journal Printer Link has been busied out and the link is torn down. Enter `release journal wakeup-log | pms-log` to restore the link.
- c. **Error Type 257:** Link Retry test (#215) failed. Physical link cannot be set up, usually because of hardware problems such as power off or cable disconnect. See [Procedures for Restoring the PMS Printer Link](#).
- d. **Error Type 513:** physical link cannot be set up, usually because of hardware problems such as power off or cable disconnect. The PMS Printer Link physical link is down due to the following causes: cable to the printer device is disconnected, the printer device is powered off, or the data extension where the printer device connects to has been busied out. Check the connectivity of wire and cable among wall jacket, data module, and the printer device. Enter `status data extension` and verify that the data extension of the printer device is in the in-service/idle state. If the data extension is not available, see [Procedures for Restoring the PMS Printer Link](#).

- e. **Error Type 769:** link idle timer, link comes down. The printer device is in an off-line state, for example, paper jam or paper out. Check the printer device and act promptly to put it back to on-line state. Enter `test journal wakeup-log | pms-log` to set up the printer link.

---

## Demand test descriptions and error codes

Investigate tests in the order presented. By clearing errors associated with the first test, errors generated from other tests may also be cleared. Click on the link to see the full description of the test, error codes, and recommended actions.

| Order of Investigation                     | Short Test Sequence | Long Test Sequence | D/ND           |
|--------------------------------------------|---------------------|--------------------|----------------|
| <a href="#">Link Tear Down Test (#213)</a> |                     | X                  | Destructive    |
| <a href="#">Link Retry Test (#215)</a>     | X                   | X                  | Nondestructive |

# PNC-DUP (PNC Duplication)

S8700-series Fiber-PNC only

| MO Name in Log | Alarm Level | Initial Command to Run  | Full Name of MO |
|----------------|-------------|-------------------------|-----------------|
| PNC-DUP        | NA          | <code>status pnc</code> | PNC duplication |

In systems with the Critical Reliability option, the following components, which together comprise the Port Network Connectivity (PNC), are duplicated:

- 1 Expansion Interface (EI) TN570 circuit packs in the port networks (PNs)
- 1 Switch Node Interface (SNI) TN573 circuit packs in switch nodes
- 1 DS1 Converter (DS1C) TN574 circuit packs for remote PN connections
- 1 Fiber-optic cables (metallic in certain cases) connecting the above circuit packs
- 1 DS1 facilities between the DS1Cs
- 1 Switch Node Clock (SNC) TN572 circuit packs
- 1 IP Server Interface (IPSI) TN2312AP circuit packs

Although not part of the PNC, Tone-Clock circuit packs are also duplicated in each PN. The PNC is available in two different configurations: direct connect, in which each port network is connected directly by fiber optic links to each other PN; and Center Stage Switch (CSS) which utilizes one or two switch nodes to interconnect the PNs. Direct connect systems can have up to two PNs. CSS systems with one switch node can have up to 15 PNs. CSS systems with three switch node can have up to 44 PNs. See [Figure 61: Duplicated Direct Connect PNC Connectivity](#) and [Figure 62: Duplicated PNC with Center Stage Switch Connectivity](#).

PNC duplication architecture utilizes an active/standby duplication scheme, in which one complete set of PNC components supports call processing, while the duplicate PNC is held in reserve. All calls on the active PNC are simultaneously set up, or shadowed, on the standby PNC in order for it to be capable of instantly assuming active status when necessary, allowing for interchanges without service disruption (in the case of single faults).

The PNC-DUP MO tracks the health of the active and standby PNCs, controls planned and spontaneous interchanges, and manages related functions such as double call refresh and unrefresh, anti-thrashing, and so on. The main responsibility of PNC-DUP is to recover the system to full service in the event of a fault. In the event of multiple faults PNC-DUP will do its best to maximize service continuity.

PNC duplication does not introduce any additional types of hardware or hardware faults, and there are no tests associated with the PNC-DUP MO. Instead, error log entries are used to log useful information about the occurrence and causes of interchanges. This is done in order to facilitate diagnosis of problems, which can then be addressed by using the documentation for the individual MO involved.

---

## PNC-DUP Related Commands

The following commands are described in *Maintenance Commands Reference (03-300431)*.

|                              |                                                                                                                                                                   |
|------------------------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>status pnc</b>            | Lists information about the operational status of both PNCs including state of health, alarms, busyouts and locks.                                                |
| <b>reset pnc interchange</b> | Initiates a demand PNC interchange. If the standby is healthy with state of health indexes all 0, there is no effect on service. Otherwise, calls may be dropped. |
| <b>set pnc</b>               | Locks or unlocks the active PNC, preventing interchanges. It does not interfere with double call setup.                                                           |
| <b>busyout pnc</b>           | Removes the standby PNC from service. See also <a href="#">Busyouts and PNC-DUP</a> .                                                                             |

---

## Busyouts and PNC-DUP

The **busyout pnc** command puts the standby PNC in the busyout state, and call set up is turned off.

- 1 The standby PNC is unrefreshed; existing duplicate call connections are removed.
- 1 PNC interchanges are prevented.

Upon release, interchanges are re-enabled and a global refresh of double call setup on the standby is performed.

When PNC duplication is in effect:

- 1 An active PNC component cannot be busied-out.
- 1 A standby PNC component can only be busied-out when the standby PNC is first busied-out.
- 1 The standby PNC cannot be released unless all standby PNC components are released.

**Figure 61: Duplicated Direct Connect PNC Connectivity**

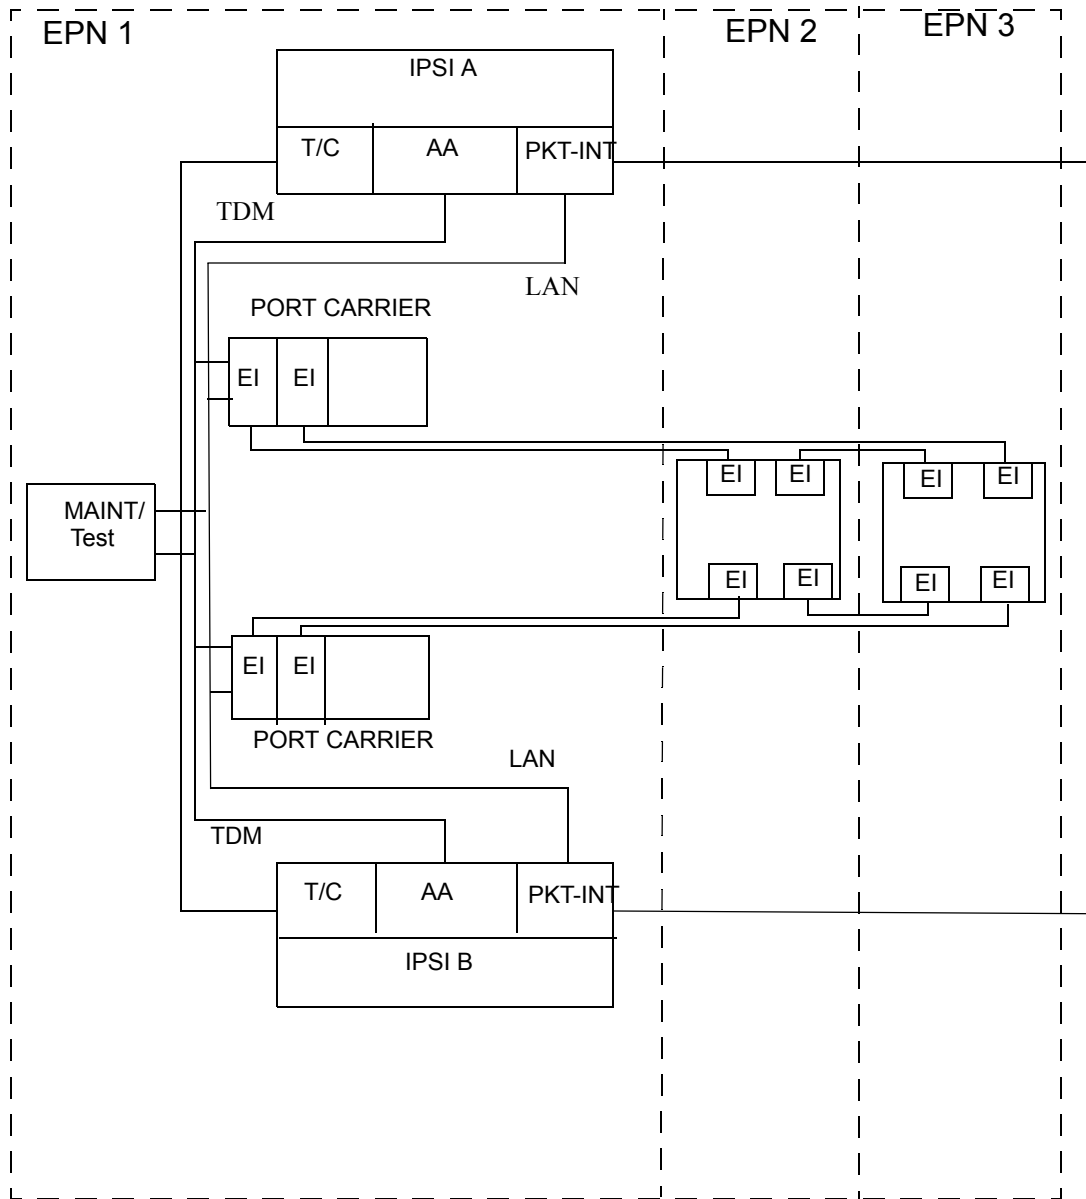

Figure 62: Duplicated PNC with Center Stage Switch Connectivity

---

## Enabling and Removing PNC Duplication

### Note:

PNC duplication requires IPSI duplication.

### To Enable PNC Duplication

To enable PNC duplication:

1. Enable PNC-DUP on the `change system-parameters customer-options` screen.
2. Fully administer duplicate fiber link connectivity. Verify by entering `list fiber-link`. For IP Duplication go to Step [3](#).
3. Fully administer IPSI duplication (`ipserver-interface duplication`). Verify by using `list ipserver-interface`.
4. Turn on PNC-DUP using the `change system-parameters duplication` screen. This is not allowed if any component of either PNC (A or B) is busied out.
5. The system must insert all connectivity-related components for both standby and active PNC. For CSS configurations this takes up to 5 minutes depending upon CSS circuit pack insertion. For Direct Connect configurations this is declared complete at 5 minutes after the first appearance of the terminal login prompt.
6. The PNC-DUP initialization anti-thrashing timer must expire (this occurs 5 minutes after completion of board insertion, PNC interchange, or system reset of level 2 or higher).

### To Disable PNC Duplication

To disable PNC duplication perform the following sequence of steps:

1. Verify that the A-PNC is active. A forced interchange may be required. See `reset pnc` in Chapter 8.
2. Busyout the standby PNC (B-PNC).
3. Turn off the system parameter for PNC-DUP using `change system-parameters duplication`.

After PNC duplication has been removed, configuration audits generate the alarm shown below and possibly others. To clear this alarm, the B-PNC fibers, circuit packs in switch node carriers (EIs, SNIs, SNCs, and DS1Cs), and switch node carriers must be removed as outlined in the following steps.

```
01D SN_CONF 5000 255
```

In this case, 01D is the B-PNC switch node from which duplication was removed.

4. Remove the B-PNC fibers by removing the Endpoint Board Locations on the **change fiber-link** screen for all fibers. For fibers using DS1Cs, remove the B-PNC DS1C Board Locations on the **change fiber-link** screen.
5. Remove the B-PNC circuit packs starting with the switch node carrier most distant from the server complex. Use **change circuit-pack location**, page to the B-PNC carrier and remove all of the circuit packs there. Remove all circuit packs in the other B-PNC switch node carriers.

If the Expansion Interface circuit pack associated with the PN is located in the switch node carrier closest to the server, it cannot be removed from translation until it has been busied-out and disconnected from the carrier slot.

When SNI, SNC, or DS1C circuit packs are removed from a B-PNC carrier, any alarms against them should be resolved.

6. Remove the B-PNC switch node carriers. Use **change cabinet location** and enter **not-used** for B-PNC carriers.

Any alarm against the carrier such as 01D SN-CONF should be resolved. The B-PNC carriers and associated circuit packs should not be alarmed.

7. Disable PNC duplication on the **change system-parameters customer-options** screen by changing **PNC Duplication** to **no**.

If an alarm exists against any Expansion Interface circuit pack connected to a B-PNC carrier, use **test board location long clear** to clear the alarm.

Alterations to PNC which involve only the *addition* of fiber connectivity can be done with PNC-DUP operational. Alterations requiring the *removal* of fiber connectivity must be done with PNC-DUP removed. PNC-DUP must be removed and translations should be saved before any hardware changes are made.

---

## Steady State LEDs

The LEDs of PNC components in a stable duplicated system should appear as follows:

- 1 The active IPSIs are functioning as archangels in IPSI port networks.
- 1 The active EIs in the PNs are functioning as archangels. Their LEDs flash in a pattern of 2 seconds on 200 milliseconds off (PN *without* an IPSI).
- 1 The PN standby EIs amber LEDs are off (PN *without* an IPSI).
- 1 The PN active EI amber LED is on solid (PN *with* an IPSI).
- 1 The PN standby EI amber LED is off (PN *with* an IPSI).
- 1 The SNIs on the active switch node(s) have amber LEDs on solid.
- 1 The SNIs on the standby switch node(s) have amber LEDs off.
- 1 Active DS1Cs amber LEDs are on solid.

- 1 Standby DS1Cs amber LEDs are off.
- 1 DS1C facility green LEDs are on if the corresponding facility is equipped.

---

## PNC State of Health

PNC-DUP software monitors the health of the two PNCs as determined by their state of health (SOH) vectors, and initiates an interchange when the health of the active falls below that of the standby (unless prevented from doing so by a PNC lock, busyout, or anti-thrashing mechanism). Potentially service-disrupting faults which occur in PNC components are reported to PNC-DUP and incorporated in the state of health for the affected PNC. The SOHs of both PNCs are displayed on the **status pnc** screen.

## PNC State-of-Health Indexes

The Inter-PN and Inter-SN Indexes form the state of health vector, which is used to track and compare the states of health of both PNCs. The fields making up the indexes are two digit numbers separated by periods (.), with each field representing a different class of faults. The fault class fields are arranged in order of decreasing importance from left to right. In other words, each field in the index supersedes the following fields in determining which PNC is healthiest. A fault class drives an interchange only when all of the higher priority fault classes are equal. A zero entry indicates no faults in that class. Increasing numbers indicate increasingly higher numbers of faults present in that class.

The Inter-PN Index contains six fields (XX.XX.XX.XX.XX.XX), and the Inter-SN Index has two (XX.XX). The Inter-PN Index reports faults in connectivity between port networks and supersedes the Inter-SN Index, which reports faults in connectivity between switch nodes. (The Inter-SN Index is only meaningful for systems with a center stage switch having two switch nodes, each of which is duplicated).

The meaning of each fault class field is given in [Table 212: PNC State-of-Health Fault Classes](#). A zero entry indicates that there are no such faults reported. Higher numbers indicate increasing number of faults. All zeros indicates perfect state of health. Unless the PNCs are locked, the active PNC's state of health should always be equal to or better than the standby's. (Otherwise, the system would perform a spontaneous interchange.)

After a PNC-related alarm is cleared, the system performs a partial refresh of the standby PNC. The corresponding fault class field is not updated to reflect the improved state of health until the refresh is done. The state of health indexes will not agree with the current alarm status during this period.

**Table 212: PNC State-of-Health Fault Classes**

| Fault Class         | Priority | Description                                                                                                                                       | MOs                                                      |
|---------------------|----------|---------------------------------------------------------------------------------------------------------------------------------------------------|----------------------------------------------------------|
| FC_EAL              | 1        | Number of PNs with EALs down                                                                                                                      | EXP-PN                                                   |
| FC_INL              | 2        | Number of PNs with LINL, RINL, or EI-SNI neighbor link faults                                                                                     | EXP-PN,<br>SN-CONF                                       |
| FC_BFD <sup>1</sup> | 3        | Number of PNs with BFDL (Bearer Fault Detection Link) faults                                                                                      | SYS-LINK                                                 |
| FC_HW               | 4        | Number of PNs affected by hardware faults in a link having an EI as an endpoint (Endpoints can be determined with <code>list fiber-link</code> .) | EXP-INTF,<br>SN-CONF,<br>FIBER-LK,<br>SNI-BD,<br>DS1C-BD |
| FC_PER              | 5        | Number of PNs affected by SNI peer link faults for SNIs connected to EIs                                                                          | SNI-PEER                                                 |
| FC_DS1              | 6        | Number of PNs affected by DS1C facility faults                                                                                                    | DS1FAC                                                   |

**Table 212: PNC State-of-Health Fault Classes**

| <b>Fault Class</b> | <b>Priority</b> | <b>Description</b>                                                          | <b>MOs</b>                      |
|--------------------|-----------------|-----------------------------------------------------------------------------|---------------------------------|
| FC_SNIL            | 7               | Number of inter-switch-node fibers affected by peer or neighbor link faults | SNI-PEER                        |
| FC_SNIHW           | 8               | Number of interswitch-node fibers affected by hardware faults               | SN-CONF,<br>SNI-BD,<br>FIBER-LK |

1. BFDLs only exist in Port networks that have an IPSI. Port networks that do not have an IPSI will have the EI as Archangel and no BFDL faults.

In multi-node CSS configurations FC\_DS1 is considered less critical than FC\_SNINL since DS1C constraints affect only one PN and indicate restricted bandwidth. However FC\_SNINL can indicate problems for all PNs on the far end switch node (the one downlink from the PN). If the DS1C problem is critical (for example, loss of all bandwidth to the affected PN) a constraint with a higher order fault class will be reported to PNC DUP.

---

## Resolving Poor State of Health

When the SOHs for both PNCs are not all zeros, identify and repair the problem:

1. Look for PNC component alarms (major or minor) for the PNC side whose SOH is not all zero. First repair the standby PNC.
2. Busy-out the standby PNC.
3. Follow the diagnostic and repair procedures for the alarmed PNC components just as with a unduplicated PNC. Examine the alarm logs and error logs to isolate the fault.
4. Verify that the related PNC SOH is restored to all zeros.
5. Release the standby PNC for busy-out.

---

## Refresh and Unrefresh of the Standby PNC

In a fully functional PNC with healthy standby and active sides, the standby PNC has a complete set of call connections corresponding to those in the active PNC. If, however, the state of health of the standby PNC degrades, a selective unrefresh of those connections which utilize the faulted component(s) is performed. If the health of the standby PNC improves, a selective refresh of connections on the affected route is performed, so that call setup is consistent between the active PNC and the healthy parts of the standby PNC.

The **Standby Refreshed** field on the **status pnc** screen does not refer to the selective type of refresh. It refers only to a global refresh that is performed when:

1. The system is initialized and PNC duplication is enabled.

- 1 There has been a spontaneous PNC interchange.
- 1 The standby PNC has been released from busy-out.
- 1 A system reset of level 2 or higher has taken place.

The **Refreshed** field may show **y** when the standby is partially unrefreshed. An interchange into an incompletely refreshed standby results in dropped calls. This can happen when a more severe fault occurs on the active PNC, or when `set pnc interchange` is used with the override option.

---

## PNC Interchanges

PNC spontaneous interchanges occur when PNC duplication software determines that the SOH of the standby PNC is better than that of the active PNC. PNC-DUP executes a spontaneous interchange only when a message from a PNC component MO sends a message indicating that either a fault has occurred on the active PNC, or a fault has been resolved on the standby PNC such that the state of health of the active PNC is now lower than that of the standby.

This message will usually indicate the type and location of the failed connectivity component. A corresponding major or minor alarm is logged by the reporting MO, stimulating an alarm report.

In the less common situation when the resolution of a fault on the standby renders it more healthy than a simultaneously faulted active PNC, the message will indicate the type and location of the *improved* component.

Once the interchange completes, the failed component will be on the standby PNC. A demand interchange can be requested in the presence or absence of standby PNC faults. The following sequence of actions can be observed during a fault-free interchange:

1. The Expansion Interfaces currently acting as archangels in the PNs are deactivated as indicated by the amber LEDs going from flashing to on solid.
2. The EIs in IPSI port networks are interchanged as indicated by the new standby EI amber LED off and the new active EI amber LED on solid.
3. One by one the EIs in non IPSI port networks are interchanged as indicated by new standby EI amber LED turning off and the new active EI amber LED flashing (2 seconds on, 200 milliseconds off). At this point the interchange is functionally complete.
4. The SNIs amber LEDs are updated. so that the SNIs on the active SN have amber LEDs on, while the standby SN's SNIs amber LEDs turn off.

Certain conditions may interfere with the normal execution of the interchange:

1. In a faulted spontaneous interchange it is possible the PN directly affected by the fault will be the last to interchange.
2. A user directly affected by the single fault instigating a PNC interchange can experience a momentary outage of voice path connectivity during the switch.

3. If faults exist on both the standby and active PNC, it is possible to have some PNs go out of service while others are returned to service.
4. The new standby SNIs amber LED may not be off due to a fault in the line of communication path to the standby SNIs. In a multi-fault interchange, LEDs on the new active SNIs may not be on for the same reason.

In any multi-fault situation, use `status pnc` to determine which is the active PNC.

PNC duplication informs Timing Synchronization maintenance when a PNC interchange has been completed and indicates which PNC is active. This causes Synchronization to audit and insure that the primary source for synchronization of Tone-Clocks in each PN is supplied by a path associated with the active PNC.

---

## Antithrashing and PNC Interchanges

Following a spontaneous PNC interchange, subsequent PNC interchanges are prevented for 5 minutes. This condition is indicated by a **y** in the **Interchange Disabled** field of the **status PNC** screen. After 5 minutes, the anti-thrashing timer expires, interchange decisions are re-enabled, and the field entry is **n**.

**Note:**

Should a catastrophic failure occur on the active PNC during the period when **Interchange Disabled?** is set to **y**, there will be no spontaneous PNC interchange.

Demand PNC interchanges also invoke anti-thrashing, but only for a period of 30 seconds. During anti-thrashing mode, demand interchanges are also prevented unless the override option is specified. Use of this option will cause a service disruption.

---

## Repairs on the Standby PNC Components

 **CAUTION:**

If there is a TDM-CLK alarm, system timing may be routed through part of the standby PNC, and circuit switched data may be affected by the following repair procedures. This can happen, for example, when a slave tone/clock circuit pack experiences a loss of signal and switches to receive timing from the standby EI. In this case TDM-CLK 2305 error will be logged, and the clock problem should be addressed first, if possible.

To repair PNC components in a duplicated PNC:

Most repairs involve fixing a single fault on the standby PNC.

1. Use `set pnc lock` or `busyout pnc` to prevent an interchange into the PNC being repaired.

If a faulty component exists on the currently active PNC, the standby PNC is more severely faulted. Normally the standby PNC is repaired first because it is the most severely impaired.

2. To repair the active PNC, use `reset pnc interchange override-and-lock` to request an interchange and ensure that no subsequent interchange occurs during the repair of the standby PNC.

The demand interchange may not be necessary if the following conditions drive a spontaneous interchange:

- 1 The anti-thrashing period from the last interchange has expired.
- 1 The global refresh from releasing the standby PNC has completed.

The standby PNC SOH is better than the active.

3. At this point, the faulty component is on the standby PNC, and the PNCs are locked in their current active/standby state. Busy-out the PNC.
4. Use fault isolation and component testing procedures for the individual PNC components. Replacement of components will not disrupt operation of the active PNC.
5. Once the failed component is replaced, test the standby PNC component from the terminal to ensure the replacement is functioning properly.
6. When the problem is resolved as indicated by a state of health with all zeros, (`status pnc`), unlock and release the pnc.

No further PNC interchange is required because you can test the standby PNC as thoroughly as the active.

---

## Interactions: Server Resets and PNC Interchanges

- 1 A system reset of level 1 (warm), 2 (cold2) or 4 (reboot) does not change which PNC is active. If a PNC interchange was in progress when the reset took place, the PNC interchange still goes to completion.
- 1 If a system reset level 1 (warm) takes place during a PNC interchange, the reset is escalated to level 2 (cold2).

---

## Fault Isolation Using Duplicated PNC

PNC duplication, can, in some cases aid in the isolation of faults. PNC interchanges can be used to help indict the faulty hardware. Following are two examples demonstrating this technique.

- 1 There is a fault which can occur in either an IPSI port network's EI or the PKT-INT which cannot be readily attributed to one board or the other. If the packet bus transceivers on the PKT-INT or EI fail, it will be apparent that the two boards cannot communicate, but it will not be clear which board is at fault. In this case, a planned interchange of the PNC can be used to indict one of the two boards. If the interchange cures the problem, the EI was at fault. If the interchange does not cure the problem, the PKT-INT is suspect, provided there are no PKT-BUS faults.
- 1 A similar relationship exists for the PN Archangel (active EI) and certain TDM bus problems. If the EAA cannot communicate with a port board over the TDM bus, then the EAA has a fault, the port board has a fault, or there is a problem with the TDM bus itself.
  - If TDM bus maintenance tests find no problems with the bus, then it is either the port board or the EAA. It may be simpler to replace the port board than to request a PNC interchange.
  - If it is not clear which port board may be at fault, or maintenance is being performed remotely, verify that the EAA is not at fault by executing a PNC interchange. If the interchange solves the problem, then the EAA is faulty.
  - If the problem persists after the interchange, but TDM bus maintenance finds no problem, then the port board is faulty.

---

## Error Log Entries

When a PNC interchange takes place, an error is logged against PNC-DUP with a code that conveys information about the cause of the interchange and which PNC became active. There are no alarms associated with PNC-DUP errors. There should be an alarm against the PNC component that drove the interchange.

There are no PNC-DUP test sequences. Use `status pnc` to see information regarding the status of the PNCs.

The information in the following tables helps identify areas of the Alarm Log to investigate in order to find the source of the problem.

| Error Type        | Aux Data |  | Error Code         | Aux Data |
|-------------------|----------|--|--------------------|----------|
| 00000 (a)         | None     |  | 20200 – 20263 (s)  | 1        |
| 10000 – 10063 (b) | 1        |  | 20300 – 20363 (t)  | 1        |
| 10100 – 10163 (c) | 1        |  | 20400 – 20463 (u)  | 1        |
| 10200 – 10263 (d) | 1        |  | 20500 – 20563 (v)  | 1        |
| 10300 – 10363 (e) | 1        |  | 20601 – 20664 (w)  | 1        |
| 10400 – 10463 (f) | 1        |  | 20701 – 20764 (x)  | 1        |
| 10500 – 10563 (g) | 1        |  | 21000 – 21063 (y)  | 1        |
| 10601 – 10664 (h) | 1        |  | 21100 – 21163 (z)  | 1        |
| 10701 – 10764 (i) | 1        |  | 21200 – 21263 (aa) | 1        |
| 11000 – 11063 (j) | 1        |  | 21300 – 21363 (ab) | 1        |
| 11100 – 11163 (k) | 1        |  | 21400 – 21463 (ac) | 1        |
| 11200 – 11263 (l) | 1        |  | 21601 – 21664 (ad) | 1        |
| 11300 – 11363 (m) | 1        |  | 21701 – 21764 (ae) | 1        |
| 11400 – 11463 (n) | 1        |  | 51000 (af)         | 1        |
| 11601 – 11664 (o) | 1        |  | 52000 (ag)         | 1        |
| 11701 – 11764 (p) | 1        |  | 53000 (ah)         | 1        |
| 20000 – 20063 (q) | 1        |  | 60801 (ai)         | 1        |
| 20100 – 20163 (r) | 1        |  | 60800 (aj)         | 1        |

1. The Aux Data indicates which PNC became active after the PNC interchange: “0” denotes PNC-A; “1” denotes PNC-B.

| Error Type | Aux Data | Associated Test              | Alarm Level | On/Off Board | Recommended Action           |
|------------|----------|------------------------------|-------------|--------------|------------------------------|
| 18         | None     | <code>busyout pnc-dup</code> | WRN         | ON           | <code>release pnc-dup</code> |

Notes:

- a. **Error Type 0:** an error took place in generating the Error Code.

- b. **Error Type 1000-10063:** a spontaneous PNC interchange took place in response to the retiring of an alarm on the A-PNC associated with fault class FC\_EAL. Use `status pnc` to look at the state of health indexes for the PNCs, and investigate any associated alarms. Adding 1 to the last two digits of the Error Code gives the PN number of the port network that reported the retired alarm. (10003 points to port network 4) Use `list config port-network` to show the cabinet number associated with a port network.
- c. **Error Type 10100-10163:** a spontaneous PNC interchange took place in response to the retiring of an alarm on the A-PNC associated with fault class FC\_INL. Use `status pnc` to look at the state of health indexes for the PNCs, and investigate any associated alarms. Adding 1 to the last two digits of the Error Code gives the PN number of the port network that reported the retired alarm. (10003 points to port network 4). Use `list config port-network` to show the cabinet number associated with a port network.
- d. **Error Type 10200-10263:** a spontaneous PNC interchange took place in response to the retiring of an alarm on the A-PNC associated with fault class FC\_HW. Use `status pnc` to look at the state of health indexes for the PNCs, and investigate any associated alarms. Adding 1 to the last two digits of the Error Code gives the PN number of the port network that reported the retired alarm. (10203 points to port network 4.) Use `list config port-network` to show the cabinet number associated with a port network.
- e. **Error Type 10300-10363:** a spontaneous PNC interchange took place in response to the retiring of an alarm on the A-PNC associated with fault class FC\_PER. Use `status pnc` to look at the state of health indexes for the PNCs, and investigate any associated alarms. Adding 1 to the last two digits of the Error Code gives the PN number of the port network that reported the retired alarm. (10303 points to port network 4.) Use `list config port-network` to show the cabinet number associated with a port network.
- f. **Error Type 10400-10463:** a spontaneous PNC interchange took place in response to the retiring of an alarm on the A-PNC associated with fault class FC\_DS1. Use `status pnc` to look at the state of health indexes for the PNCs, and investigate any associated alarms. Adding 1 to the last two digits of the Error Code gives the PN number of the port network that reported the retired alarm. (10403 points to port network 4.) Use `list config port-network` to show the cabinet number associated with a port network.
- g. **Error Type 10500-10563:** a spontaneous PNC interchange took place in response to the retiring of an alarm on the A-PNC associated with fault class FC\_BFD. Use `status pnc` to look at the state of health indexes for the PNCs, and investigate any associated alarms. Adding 1 to the last two digits of the Error Code gives the PN number of the port network that reported the retired alarm. (10203 points to port network 4.) Use `list config port-network` to show the cabinet number associated with a port network.
- h. **Error Type 10600-10664:** a spontaneous PNC interchange took place in response to the retiring of an alarm on the A-PNC associated with fault class FC\_SNIL. Use `status pnc` to look at the state of health indexes for the PNCs, and investigate any associated alarms. The last two digits of the Error Code indicate the fiber-link number of the fiber that reported the retired alarm. Use `list fiber-link` to show the location of the fiber.
- i. **Error Type 10700-10764:** a spontaneous PNC interchange took place in response to the retiring of an alarm on the A-PNC associated with fault class FC\_SNIHW. Use `status pnc` to look at the state of health indexes for the PNCs, and investigate any associated alarms.

The last two digits of the Error Code indicate the fiber-link number (01-64) of the fiber that reported the retired alarm. Use `list fiber-link` to show the location of the fiber.

- j. **Error Type 11000 – 11063:** a spontaneous PNC interchange took place in response to the occurrence of a major or minor alarm on the A-PNC associated with fault class FC\_EAL. This indicates that one or more Expansion Archangel Links are down. Investigate any EXP-PN alarms. Adding 1 to the last two digits of the Error Code gives the PN number of the port network that reported the alarm. (11003 points to port network 4.) Use `list config port-network` to show the cabinet number associated with a port network.
- k. **Error Type 11100 – 11163:** a spontaneous PNC interchange took place in response to the occurrence of a major or minor alarm on the A-PNC associated with fault class FC\_INL. This indicates that one or more neighbor or indirect neighbor links with an EI as an endpoint have experienced faults. Investigate any alarms against EXP-PN and SN-CONF. Adding 1 to the last two digits of the Error Code gives the PN number of the port network that reported the alarm. (11103 points to port network 4.) Use `list config port-network` to show the cabinet number associated with a port network.
- l. **Error Type 12000 – 11263:** a spontaneous PNC interchange took place in response to the occurrence of a major or minor alarm on the A-PNC associated with fault class FC\_HW. This indicates that one or more neighbor or indirect neighbor links with an EI as an endpoint have experienced faults. Investigate any alarms against EXP-PN and SN-CONF. Adding 1 to the last two digits of the Error Code gives the PN number of the port network that reported the alarm. (11203 points to port network 4.) Use `list config port-network` to show the cabinet number associated with a port network.
- m. **Error Type 11300 – 11363:** a spontaneous PNC interchange took place in response to the occurrence of a major or minor alarm on the A-PNC associated with fault class FC\_PER. This indicates one or more faults on peer links that connect SNIs to EIs. Investigate any alarms against SNI-PEER. Adding 1 to the last two digits of the Error Code gives the PN number of the port network that reported the alarm. (11303 points to port network 4.) Use `list config port-network` to show the cabinet number associated with a port network.
- n. **Error Type 11400 – 11463:** a spontaneous PNC interchange took place in response to the occurrence of a major or minor alarm on the A-PNC associated with fault class FC\_DS1. This indicates faults on one or more DS1C facilities. Investigate any alarms against DS1-FAC. Adding 1 to the last two digits of the Error Code gives the PN number of the port network that reported the alarm. (11403 points to port network 4.) Use `list config port-network` to show the cabinet number associated with a port network.
- o. **Error Type 11601 – 11664:** a spontaneous PNC interchange took place in response to the occurrence of a major or minor alarm on the A-PNC associated with fault class FC\_SNIL. This indicates one or more faults on peer or neighbor links between SNIs on different switch nodes. Investigate any alarms against SNI-PEER. The last two digits of the Error Code indicate the fiber-link number of the fiber that reported the retired alarm. Use `list fiber-link` to show the location of the fiber.
- p. **Error Type 11701 – 11764:** a spontaneous PNC interchange took place in response to the occurrence of a major or minor alarm on the A-PNC associated with fault class FC\_SNIHW. This indicates one or more faults on hardware connecting SNIs on different switch nodes.

Investigate any alarms against SN-CONF, SNI-BD, FIBER-LK. The last two digits of the Error Code indicate the fiber-link number of the fiber that reported the retired alarm. Use `list fiber-link` to show the location of the fiber.

- q. **Error Type 20000 – 20063:** a spontaneous PNC interchange took place in response to the retiring of an alarm on the B-PNC associated with fault class FC\_EAL. Use `status pnc` to look at the state of health indexes for the PNCs, and investigate any associated alarms. Adding 1 to the last two digits of the Error Code gives the PN number of the port network that reported the retired alarm. (20003 points to port network 4.) Use `list config port-network` to show the cabinet number associated with a port network.
- r. **Error Type 20100 – 20163:** a spontaneous PNC interchange took place in response to the retiring of an alarm on the B-PNC associated with fault class FC\_INL. Use `status pnc` to look at the state of health indexes for the PNCs, and investigate any associated alarms. Adding 1 to the last two digits of the Error Code gives the PN number of the port network that reported the retired alarm. (20103 points to port network 4.) Use `list config port-network` to show the cabinet number associated with a port network.
- s. **Error Type 20200 – 20263:** a spontaneous PNC interchange took place in response to the retiring of an alarm on the B-PNC associated with fault class FC\_HW. Use `status pnc` to look at the state of health indexes for the PNCs, and investigate any associated alarms. Adding 1 to the last two digits of the Error Code gives the PN number of the port network that reported the retired alarm. (20203 points to port network 4.) Use `list config port-network` to show the cabinet number associated with a port network.
- t. **Error Type 20300 – 20363:** a spontaneous PNC interchange took place in response to the retiring of an alarm on the B-PNC associated with fault class FC\_PER. Use `status pnc` to look at the state of health indexes for the PNCs, and investigate any associated alarms. Adding 1 to the last two digits of the Error Code gives the PN number of the port network that reported the retired alarm. (20303 points to port network 4.) Use `list config port-network` to show the cabinet number associated with a port network.
- u. **Error Type 20400 – 20463:** a spontaneous PNC interchange took place in response to the retiring of an alarm on the B-PNC associated with fault class FC\_DS1. Use `status pnc` to look at the state of health indexes for the PNCs, and investigate any associated alarms. Adding 1 to the last two digits of the Error Code gives the PN number of the port network that reported the retired alarm. (20403 points to port network 4.) Use `list config port-network` to show the cabinet number associated with a port network.
- v. **Error Type 20500 – 20563:** a spontaneous PNC interchange took place in response to the retiring of an alarm on the B-PNC associated with fault class FC\_BFD. Use `status pnc` to look at the state of health indexes for the PNCs, and investigate any associated alarms. Adding 1 to the last two digits of the Error Code gives the PN number of the port network that reported the retired alarm. (20503 points to port network 4.) Use `list config port-network` to show the cabinet number associated with a port network.
- w. **Error Type 20600 – 20664:** a spontaneous PNC interchange took place in response to the retiring of an alarm on the B-PNC associated with fault class FC\_SNIL. Use `status pnc` to look at the state of health indexes for the PNCs, and investigate any associated alarms. The last two digits of the Error Code indicate the fiber-link number (01-27) of the fiber that reported the retired alarm. Use `list fiber-link` to show the location of the fiber.

- x. **Error Type 20700 – 20764:** a spontaneous PNC interchange took place in response to the retiring of an alarm on the B-PNC associated with fault class FC\_SNIHW. Use `status pnc` to look at the state of health indexes for the PNCs, and investigate any associated alarms. The last two digits of the Error Code indicate the fiber-link number (01-27) of the fiber that reported the retired alarm. Use `list fiber-link` to show the location of the fiber.
- y. **Error Type 21000-21063:** a spontaneous PNC interchange took place in response to the occurrence of a major or minor alarm on the B-PNC associated with fault class FC\_EAL. This indicates that one or more Expansion Archangel Links are down. Investigate any EXP-PN alarms. Adding 1 to the last two digits of the Error Code gives the PN number of the port network that reported the alarm. (21003 points to port network 4.) Use `list config port-network` to show the cabinet number associated with a port network.
- z. **Error Type 21100-21163:** a spontaneous PNC interchange took place in response to the occurrence of a major or minor alarm on the B-PNC associated with fault class FC\_INL. This indicates that one or more neighbor or indirect neighbor links with an EI as an endpoint have experienced faults. Investigate any alarms against EXP-PN and SN-CONF. Adding 1 to the last two digits of the Error Code gives the PN number of the port network that reported the alarm. (21103 points to port network 4.) Use `list config port-network` to show the cabinet number associated with a port network.
- aa. **Error Type 21200-21263:** a spontaneous PNC interchange took place in response to the occurrence of a major or minor alarm on the B-PNC associated with fault class FC\_HW. This indicates that one or more neighbor or indirect neighbor links with an EI as an endpoint have experienced faults. Investigate any alarms against EXP-PN and SN-CONF. Adding 1 to the last two digits of the Error Code gives the PN number of the port network that reported the alarm. (21203 points to port network 4.) Use `list config port-network` to show the cabinet number associated with a port network.
- ab. **Error Type 21300-21363:** a spontaneous PNC interchange took place in response to the occurrence of a major or minor alarm on the B-PNC associated with fault class FC\_PER. This indicates faults on peer links that connect SNIs to EIs. Investigate any alarms against SNI-PEER. Adding 1 to the last two digits of the Error Code gives the PN number of the port network that reported the alarm. (21303 points to port network 4.) Use `list config port-network` to show the cabinet number associated with a port network.
- ac. **Error Type 21400-21463:** a spontaneous PNC interchange took place in response to the occurrence of a major or minor alarm on the B-PNC associated with fault class FC\_DS1. This indicates faults on one or more DS1C facilities. Investigate any alarms against DS1-FAC. Adding 1 to the last two digits of the Error Code gives the PN number of the port network that reported the alarm. (21403 points to port network 4.) Use `list config port-network` to show the cabinet number associated with a port network.
- ad. **Error Type 21600-21664:** a spontaneous PNC interchange took place in response to the occurrence of a major or minor alarm on the B-PNC associated with fault class FC\_SNIL. This indicates faults on peer or neighbor links between SNIs on different switch nodes. Investigate any alarms against SNI-PEER. The last two digits of the Error Code indicate the fiber-link number (01-27) of the fiber that reported the alarm. Use `list fiber-link` to show the location of the fiber.

- ae. **Error Type 21700-21764:** a spontaneous PNC interchange took place in response to the occurrence of a major or minor alarm on the B-PNC associated with fault class FC\_SNIHW. This indicates faults on hardware connecting SNIs on different switch nodes. Investigate any alarms against SN-CONF, SNI-BD, FIBER-LK. The last two digits of the Error Code indicate the fiber-link number (01-27) of the fiber that reported the alarm. Use `list fiber-link` to show the location of the fiber.
- af. **Error Type 51000:** a spontaneous PNC interchange took place upon the expiration of the anti-thrashing timer.
- ag. **Error Type 52000:** a spontaneous PNC interchange took place upon the unlocking of the PNCs with the `set pnc unlock` command.
- ah. **Error Type 53000:** a spontaneous PNC interchange took place upon the completion of a global refresh of the standby.
- ai. **Error Type 60801:** a demand interchange was executed with `reset pnc interchange`.
- aj. **Error Type 60800:** a demand interchange was executed with `reset pnc interchange` using the `override-and-lock` option.

## POWER

### S8700-series Fiber-PNC

This section covers maintenance for:

- 1 [Battery and Charger for AC-Powered Systems](#)
- 1 [Battery and Charger for DC-Powered Systems](#)

---

## Battery and Charger for AC-Powered Systems

| MO Name in Log | Alarm Level | Initial Command to Run                       | Full Name of MO             |
|----------------|-------------|----------------------------------------------|-----------------------------|
| POWER          | MIN         | <code>test environment c</code> <sup>1</sup> | Battery and Battery Charger |

1. **C** is the cabinet number indicated in the PORT field from the Alarm or Error Log.

Two different cabinet types: multicarrier and single carrier. Single carrier cabinets are used only for PNs. Both cabinet types may be powered by AC or DC external power source. Environmental maintenance differs according to cabinet type and external power supply.

AC-powered multicarrier cabinets can be equipped with rechargeable batteries that provide backup power during short power outages. Battery backup is optional on cabinets powered by an uninterruptable power supply (UPS), and is required on those that are not. DC-powered cabinets and single-carrier cabinets do not have battery backup, and this MO is not valid for those cabinets.

The battery backup for the J58890CH unit consists of one battery assembly and charger. The battery backup for the J58890CE unit consists of three 48V batteries and a battery charger. Each cabinet so equipped has its own independent battery backup unit. When power to the cabinet is interrupted, a warning alarm is logged against AC-POWER and the system draws power from the backup batteries. This is known as Nominal Power Holdover (NPH). If power is restored before the NPH time expires, the alarm is resolved. If power does not return, error logs are saved to the Mass Storage System. The nominal power holdover provided is as follows:

| PN cabinet                | Holdover   |
|---------------------------|------------|
| All carriers              | 15 seconds |
| Expansion control carrier | 10 minutes |

When AC power is restored after an outage, the battery charger fully recharges the batteries within 30 hours.

In a multicarrier-cabinet system, the Battery and Battery Charger MO represents the battery charger and the battery which are located in the lower left corner of the cabinet. Should anything go wrong with the battery or charger, they must be replaced using the procedure described in [Replacing the Battery and Battery Charger \(J58890CE\)](#). The system will detect one of the following three problems with the batteries or charger:

- 1 Reserve Fault: the charger has detected a problem within itself or the batteries and has notified the system.
- 1 High Charge Rate: the batteries have been charging at a high charge rate for an excessively long period of time. This indicates that there is a short in the batteries or the charger.
- 1 Prepare to Disconnect (Low Battery): the batteries are in danger of being drained to a point where the batteries would be damaged. This warning often occurs after multiple power failures.

The batteries take 30 hours to fully charge after being drained. A fully charged battery pack should bridge two power failures without causing a low battery warning to occur.

### **Replacing the Battery and Battery Charger (J58890CE)**

1. Move the power switch on the battery charger to OFF.  
Always turn off the battery charger before replacing the batteries. Failure to do so will result in damage to the 397C battery charger.
2. Disconnect the cord from the outlet on the front of the battery charger.
3. Remove the screw at the top left of the cover and open the cover to access the charger.
4. Check the battery voltages at the test points. Check all 3 batteries wired in series (the voltage should be 144 Volts, 3 X 48 Volts = 144 Volts).

**Note:**

An ordinary voltmeter can be used to check battery voltages at the test points, but it may not produce valid results. If the battery voltage readings are below 48 Volts (the voltages at test points should read 144 Volts, 3 x 48 Volts = 144 Volts), the battery is probably defective. However, a normal voltage reading does not necessarily mean the battery is good; under load, a defective battery with a normal reading on the voltmeter may discharge rapidly.

5. Check the battery dates and the preventive maintenance log. Replace the batteries if they are more than 2.5 years old.

**Note:**

If any defective batteries are found, replace all of them. Batteries are ordered in sets of three and should be replaced as such.

6. If no defective batteries are found, replace the entire charger.
7. Close the cover and secure it with the screw.
8. Reconnect the cord and move the power switch to ON.

## Replacing the Battery Assembly (J58890CH)

The batteries are replaced as an entire assembly.

1. Check the battery voltages at the test points on the BIU (Battery Interface Unit).
2. Remove the BIU from the power distribution unit.
3. Disconnect the battery plug from the power distribution unit (J20).
4. Remove the battery assembly from the rear of the cabinet.
5. Install the new battery assembly in the reverse order.
6. Plug the BIU back into the power distribution unit.

---

## Battery and Charger for DC-Powered Systems

| MO Name in Log | Alarm Level | Initial Command to Run           | Full Name of MO             |
|----------------|-------------|----------------------------------|-----------------------------|
| POWER          | MIN         | test environment UU <sup>1</sup> | Battery and Battery Charger |

1. **UU** is the cabinet number indicated in the PORT field from the Alarm or Error Log.

### Note:

This MO applies to the J58890CE and the J58890CH-1 with large battery holdover.

This MO represents the battery backup unit found in AC-powered multicarrier cabinets. Because the system does not recognize the type of external power, this MO exists in DC-powered multicarrier cabinets but serves no functional purpose. In such cabinets, every POWER test should always pass or abort, and no POWER alarms should be raised.

Two different types of PN cabinets are supported: multicarrier and single-carrier. Both cabinet types may be powered by either AC or DC external power source. Environmental maintenance differs according to cabinet type and external power supply.

## Battery Holdover (Large Batteries)

The large batteries are mounted inside a separate battery cabinet and can supply holdover times of 2 to 8 hours depending on the size of the battery. The batteries are circuit breaker protected and are charged by the J58890CH-1. The batteries also contain a thermal sensor that change the charging voltage depending on the battery temperature.

## Error log entries and recommended actions

Table 213: POWER Error Log Entries

| Error Type | Aux Data     | Associated Test                                    | Alarm Level | On/Off Board | Recommended Action  |
|------------|--------------|----------------------------------------------------|-------------|--------------|---------------------|
| 0 (a)      | 0            | Any                                                | Any         | Any          | test environment UU |
| 1          | Any          | Battery and Power Supply Query (#5) (Error Code 8) | MIN         | ON           | test environment UU |
| 257        | Any          | Battery and Power Supply Query (#5) (Error Code 4) | MIN         | ON           | test environment UU |
| 769        | Any          | Battery and Power Supply Query (#5) (Error Code 2) | MIN         | ON           | test environment UU |
| 3840 (b)   | 1005<br>1028 | Battery and Power Supply Query (#5)                |             |              | test environment UU |

Notes:

- a. **Error Type 0:** run the short test sequence first. If every test passes, run the long test sequence. Refer to each test's description, and follow its procedures.
- b. **Error Type 3840:** this error is valid only for AC-powered multicarrier cabinets with battery backup. For DC-powered cabinets, ignore the error; it cannot be cleared. For AC-powered cabinets, see if the battery charger is connected. If the cabinet is powered by a UPS, there is no battery backup and this error can be ignored.

## Demand test descriptions and error codes

Investigate tests in the order presented. By clearing errors associated with the first test, errors generated from other tests may also be cleared. Click on the link to see the full description of the test, error codes, and recommended actions.

| Order of Investigation                                       | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |

1. D = Destructive, ND = Nondestructive

# POW-SUP (Power Supply)

G650

| MO name in Log | Alarm level <sup>1</sup> | Initial Command to Run                | Full name of MO |
|----------------|--------------------------|---------------------------------------|-----------------|
| POW-SUP        | MAJ<br>MIN<br>WRN        | <code>test board location long</code> | Power Supply    |

1. This is a minor alarm if there is a redundant power supply, and a major alarm if there is only one power supply.

The POW-SUP maintenance object notes the presence of each power supply and the voltage of each power supply in the G650.

This MO:

- 1 Verifies that a power supply that is administered is physically present
- 1 Verifies that each output voltage (+5V, -5V, and -48V for the power supplies and +12V for the fan) is within tolerance
- 1 Is used with the `recycle carrier` command to momentarily turn off and on the power to a specified power supply or to a specified carrier
- 1 Is used to turn off output voltages from one power supply to verify that the other supply can support the entire load of the G650 (This is used only when a G650 has redundant power supplies.)

There is one instance of this MO for each 655A power supply equipped in a G650 stack. Refer to [G650 Cabinet Environmental Hardware Components](#) for further information.

If you have redundant power supplies, and both are operating, you can unplug one power supply and leave it unplugged for ten minutes without causing an alarm. If the remaining operating power supply has an alarm, the system does not wait ten minutes to generate an alarm. It generates an alarm immediately. If the power supply is unplugged for more than ten minutes, the system generates a warning alarm with an Error Code 23. If you need the power supply to be unplugged for more than ten minutes, and you do not want the system to generate an alarm, use the `change circuit-pack` command to un-administer the power supply.

## Recycle carrier

The `recycle carrier` command is useful for three different troubleshooting actions:

- 1 To verify that a redundant power supply can carry the full load. This is done by entering `recycle carrier location` with the slot number of the power supply that is to be momentarily shut down.

Each power supply monitors the voltage on the backplane and not the voltages from the power supply itself. Therefore, when redundant power supplies are present, the only way to check the voltages from each power supply is to use the recycle power supply command with the slot number chosen to force the other power supply to be tested when it is the only supply on the backplane.

- 1 To momentarily shut the power off for an entire carrier that is not a control carrier to force all the boards in the carrier to be power cycled. This is done by entering `recycle carrier location`.

### Note:

When redundant power supplies are present, this test may generate error log entries for either power supply in the carrier.

- 1 To momentarily shut the power off for a control carrier to force the EPN to go down and back up with a port network COLD restart. This is done by entering `recycle carrier location override` for a G650 carrier with an active IPSI.

For the case where duplicate IPSIs are present in a port network, the `set ipserver` command can be used to put an IPSI in the standby mode, so that a recycle of the carrier containing that IPSI will not cause a reset of the EPN.

The following test results may be obtained from the `recycle carrier` command:

| Failure Code | Description                                                                                                                                                                                                                                                                                                                                                                                               |
|--------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1            | Output voltages for the power supply under test are out of tolerance after the power was restored.                                                                                                                                                                                                                                                                                                        |
| 2            | When redundant power supplies are present, the output voltages for the other power supply are out of tolerance after the power was restored.                                                                                                                                                                                                                                                              |
| 16           | When redundant power supplies are present, and the slot number is specified, the output voltages for the other power supply are out of tolerance during the time that power supply is the only power supply providing power.<br>If it is acceptable to disrupt service temporarily, remove the good power supply and run <code>test board</code> for the other power supply to verify that it has failed. |

### Note:

It is unlikely that failure codes 1 or 2 will occur when redundant power supplies are present, because each power supply is measuring the backplane voltage instead of the power supply voltage.

## Error log entries and recommended actions

**Table 214: POW-SUP Error Log**

| Error Type | Aux Data | Associated Test                     | Alarm Level <sup>1</sup> | On/Off Board | Recommended Action                               |
|------------|----------|-------------------------------------|--------------------------|--------------|--------------------------------------------------|
| 1 (a)      | Any      | Power supply detection test (#1535) | MAJ<br>MIN               | ON           | test environment location<br>test board location |
| 23 (b)     |          | Power supply detection test (#1535) | WRN                      | ON           | test board location                              |
| 257 (c)    |          | Power supply recycle test (#1534)   | MAJ<br>MIN               | ON           | recycle carrier location [override]              |

| 769 (e)    |          | Power supply voltage test (#1536)   | MAJ<br>MIN               | ON           | test environment location<br>test board location |
| 1025 (f)   |          | Power supply voltage test (#1536)   | MAJ<br>MIN               | ON           | test environment location<br>test board location |
| 1281 (g)   |          | Power supply voltage test (#1536)   | MAJ<br>MIN               | ON           | test environment location<br>test board location |
| 1537 (h)   | Any      | Power supply detection test (#1535) | MAJ<br>MIN               | ON           | test board location                              |
| 1793 (i)   | Any      | Power supply detection test (#1535) | MAJ<br>MIN               | ON           | test board location                              |
| 2049 (j)   |          | Power supply detection test (#1535) | MIN<br>WRN               | ON           | test board location                              |
| 2305 (k)   |          | Power supply aux sig test (#1649)   | MAJ<br>MIN               | ON           | test board location                              |

1. This is a MINOR alarm if there is a redundant power supply, and a MAJOR alarm if there is only one power supply.

### Notes:

- a. **Error Type 1:** power supply not detected.
- b. **Error Type 23:** the power supply is administered, but not present.
  1. Verify that the power is plugged in.
  2. Check the yellow LED to determine that the power is on.

c. **Error Type 257:** the [Power Supply Recycle Test \(#1534\)](#) failed. Aux Data shows the failure(s), according to the table below. Aux Data values may be added together.

| Aux Data | Description                                                                                          |
|----------|------------------------------------------------------------------------------------------------------|
| 1        | The power supply under test did not restore power.                                                   |
| 2        | The other power supply did not restore power.                                                        |
| 16       | The power supply under load failed when the other power supply was specified in the recycle command. |

d. **Error Type 513:** the +5V is out of tolerance (4.75 to 5.25 V (+/- 5%)).

1. Run `test board location`.
2. Run `status environment`.

e. **Error Type 769:** the -5V is out of tolerance (-4.5 to -5.5 V (+/- 10%)).

1. Run `test board location`.
2. Run `status environment`.

f. **Error Type 1025:** the -48V is out of tolerance (-44.2 to -51.8 V (+/- 8%)).

1. Run `test board location`.
2. Run `status environment`.

g. **Error Type 1281:** the +12/14V fan voltage is out of tolerance (+11.4 to +15 V). The nominal +12V is raised to +14V when there is a hot spot warning or fan failure.

1. Run `test board location`.
2. Run `status environment`.

h. **Error Type 1537:** internal failure.

1. Run `test board location`.

| Aux Data | Description                             |
|----------|-----------------------------------------|
| 1        | Analog-to-digital converter failure     |
| 2        | Digital-to-analog converter failure     |
| 4        | Internal Mux failure                    |
| 8        | EEPROM failure                          |
| 64       | Calibration contents CRC check failure  |
| 128      | Power supply firmware CRC check failure |

i. **Error Type 1793:** operational failure.

1. Run `test board location`.

| Aux Data | Description                                             |
|----------|---------------------------------------------------------|
| 1        | No AC or DC input                                       |
| 2        | The power supply is off because of a system command.    |
| 4        | Failure, voltage, temperature, or internal status fault |

j. **Error Type 2049:** input power failure. A warning alarm is generated when the problem is first detected. The alarm level will change to a Minor alarm after about 50 minutes if the problem does not clear.

1. Run `test board location`.
2. Run `status environment`.

k. **Error Type 2305:** aux sig lead failure.

1. Run `test board location`.
2. Run `status environment`.

---

## Demand test descriptions and error codes

Investigate tests in the order presented. By clearing errors associated with the first test, errors generated from other tests may also be cleared. Click on the link to see the full description of the test, error codes, and recommended actions.

| Order of investigation                               | Short Test Sequence | Long Test Sequence | Reset Test Sequence | D/ND |
|------------------------------------------------------|---------------------|--------------------|---------------------|------|
| <a href="#">Power Supply Recycle Test (#1534)</a>    |                     |                    | X                   | D    |
| <a href="#">Power Supply Detection Test (#1535)</a>  | X                   | X                  |                     | ND   |
| <a href="#">Power Supply Voltage Test (#1536)</a>    | X                   | X                  |                     | ND   |
| <a href="#">Power Supply Aux Signal Test (#1649)</a> | X                   | X                  |                     | ND   |

## PPP-PT (Control LAN Packet/Port)

| MO Name in Log | Alarm Level | Initial Command to Run               | Full Name of MO      |
|----------------|-------------|--------------------------------------|----------------------|
| PPP-PT         | MAJ<br>MIN  | <code>test port location long</code> | PPP Port Maintenance |
|                | WRN         | <code>test port location</code>      |                      |

The TN799DP Control LAN (C-LAN) circuit pack provides TCP/IP connection to adjuncts applications such as CMS, INTUITY, and DCS Networking. The C-LAN circuit pack has one 100BASE-T Ethernet connection and up to 16 DS0 physical interfaces for PPP connections. Multiple C-LAN circuit packs in a system gives additional TCP/IP capacity.

A RSCL (remote socket control link) connects the C-LAN and the server to pass call-control and other management information. Since one link serves every port on the circuit pack, maintenance of the RSCL is part of the C-LAN circuit pack maintenance.

---

## Control LAN Congestion Controls

The switch activates congestion controls on C-LAN when it detects buffers exceeding the threshold. The switch releases the congestion controls when the C-LAN reports that its buffer level has returned to normal levels.

| If congestion:                    | Then the switch:    |
|-----------------------------------|---------------------|
| Persists for a 14-minute interval | Raises MINOR alarm  |
| Exhausts buffers                  | Raises MINOR alarm  |
| Ceases for 12 minutes             | Retires MINOR alarm |

---

## Error log entries and recommended actions

Table 215: PPP-PT Error Log Entries 1 of 2

| Error Type | Aux Data | Associated Test | Alarm Level | On/Off Board | Recommended Action              |
|------------|----------|-----------------|-------------|--------------|---------------------------------|
| 0 (a)      | 0        | Any             | Any         | Any          | <code>test port location</code> |
|            |          |                 |             |              | <i>1 of 2</i>                   |

**Table 215: PPP-PT Error Log Entries 2 of 2**

| Error Type       | Aux Data | Associated Test                | Alarm Level             | On/Off Board | Recommended Action              |
|------------------|----------|--------------------------------|-------------------------|--------------|---------------------------------|
| 1 (b)            | 0        | SCOTCH Sync Looparound (#1275) | MIN                     | ON           | <i>test port location 1 r 3</i> |
| 257 (c)          | 0        |                                | WRN                     | OFF          |                                 |
| 513 (d)          | 0        |                                | MIN                     | OFF          |                                 |
| 769 (e)          | 0        |                                | WRN                     | OFF          |                                 |
| 1281 (f)         | 0        |                                |                         |              |                                 |

| 1793 to 1920 (h) | See note |                                |                         |              |                                 |
| 2305 to 2816 (i) | See note |                                |                         |              |                                 |
| 3329 (j)         | 35768    | TCP/IP Ping test (#1281)       | MIN<br>WRN <sup>1</sup> | OFF          | <i>test port location r 3</i>   |
| 3585 (k)         | 0, 1     | TDM Looparound (#1285)         | MAJ                     | ON           | <i>test port location 1 r 3</i> |
|                  |          |                                |                         |              | <b>2 of 2</b>                   |

1. Major alarms may be downgraded to Warning alarms based on the value used in `set options`.

Notes:

- a. **Error Type 0:** run the short test sequence first. If every test passes, run the long test sequence. Refer to each test's description, and follow its procedures.
- b. **Error Type 1:** SCOTCH Synchronous Looparound test (#1275) failed.
  1. Test the port (*test port location long*).
  2. See [SCOTCH Synchronous Looparound Test \(#1275\)](#) for repair procedures.
- c. **Error Type 257:** C-LAN port detected overrun or underrun condition that may indicate a hardware problem.
  1. Test for hardware problem (*test port location long*).
  2. See [SCOTCH Synchronous Looparound Test \(#1275\)](#) for repair procedures to verify repair.
  3. Clear the alarm (*test port location long clear*).

d. **Error Type 513:** PPP link lost end-to-end connectivity.

1. Test for hardware problem (`test port location long`).
2. Run [TDM Looparound Test \(#1285\)](#), and refer to its repair procedures if there is a hardware problem.

If there is no hardware problem, the switch tries to re-establish PPP link.

e. **Error Type 769:** Port received an invalid frame, which is greater than the maximum length, contains CRC errors, and/or violates the link level protocol.

1. Test the port (`test port location long`).
2. Refer to [TDM Looparound Test \(#1285\)](#) to verify repair.
3. Clear the alarm (`test port location long clear`).

f. **Error Type 1281:** the far end has requested a disconnect of a session on this link. This is a log-only error.

g. **Error Type 1537, 1538:** some or all port sessions (sockets) are down:

| If the switch indicates that: | Then it:                     |
|-------------------------------|------------------------------|
| Some of the sessions are down | Raises off-board WARNING     |
| Every session is down         | Raises off-board MINOR alarm |

1. Test the port (`test port location`).
2. See [PPP Link Status Inquiry Test \(#1279\)](#) for repair procedure to verify repair.

h. **Error Type 1793-1920:** a socket was closed due to an error. Error Type indicates the application associated with this socket; Aux Data indicates the internal application number.

| Error Type | Application         |
|------------|---------------------|
| 1793       | Unused              |
| 1794       | DCS                 |
| 1795       | AUDIX               |
| 1796       | CMS                 |
| 1797       | ISDN Gateway        |
| 1798–1920  | Reserved for future |

i. **Error Type 2305-2816:** a session is down. Aux Data indicates the session number. These are log-only errors:

1. Error Types 2305–2560 are for session numbers 1–256.
1. Error Types 2561–2816 are for session numbers 257–512.

- j. **Error Type 3329:** TCP/IP Ping test failed. A WARNING alarm is raised if the test fails twice. A MAJOR alarm is raised if the test fails 6 times.
1. Test the port (*test port location*).
  2. See [TCP/IP Ping Test \(#1281\)](#) for repair procedures.
- k. **Error Type 3585:** TDM Looparound test (#1285) failed.
1. Test the port (*test port location long*).
  2. See [TDM Looparound Test \(#1285\)](#) for repair procedures.

---

## Demand test descriptions and error codes

1. D = Destructive, ND = Nondestructive

## PRI-CDR (Call Detail Recording Link)

| MO Name in Log                | Alarm Level | Initial Command to Run                         | Full Name of MO |
|-------------------------------|-------------|------------------------------------------------|-----------------|
| PRI-CDR<br>SEC-CDR<br>CDR-LNK | MIN         | <code>test cdr primary   secondary long</code> | CDR Link        |
|                               | WRN         | <code>test cdr primary   secondary</code>      |                 |

The error entries and tests for PRI-CDR also apply to CDR-LNK and SEC-CDR.

The CDR feature records detailed call information about every incoming and outgoing call on specified trunk groups and sends this information to a CDR output device. The two physical links can be administered for connecting external CDR output devices to the system. They are identified as the primary CDR (PRI-CDR) link and the secondary CDR (SEC-CDR) link. The CDR device connects to the system via a data module (PDM, MPDM, DTDM) connected to a port on a TN754 Digital Line circuit pack that is administered as a data extension. A CDR device can also be connected through an ADU to a port on TN726B. The CDR link to the processor is through a C-LAN board. For information about C-LAN port connectivity, see [CLAN-BD \(Control LAN Circuit Pack\)](#). External CDR output devices include:

- 1 94A Local Storage Unit (LSU)
- 1 TELESEER CDR Unit
- 1 Call Accounting System (CAS)
- 1 Call Detail Recording Unit (CDRU)
- 1 Printer
- 1 Host computer
- 1 Personal computer (PC)
- 1 Customer-provided equipment

CDR Link Maintenance provides a strategy for maintaining the link between the system and an external CDR output device. The strategy includes a set of tests for periodic diagnosis, detection of errors during normal operation, actions for troubleshooting, and raising alarms for serious problems. CDR Link Maintenance uses a try-and-wait mechanism for maintaining the CDR link. If the CDR link is torn down due to an error, CDR Link Maintenance tries to bring the CDR link up. If the Link Setup fails, CDR Link Maintenance will wait for 30 seconds before the next retry. If the number of retries reaches a threshold (two), a Minor alarm is raised for service attention.

CDR Link Maintenance does not cover the maintenance of the elements composing the CDR physical link:

- 1 External CDR output device
- 1 Data Module (PDM/MPDM/DTDM) and Digital Line Port of TN754 Digital Line circuit pack
- 1 ADU and Data Line Port of TN726B Data Line circuit pack

If CDR Link Maintenance cannot restore the CDR link, the maintenance tests of these individual components of the CDR link must be executed to diagnose faults.

### Procedures for Restoring the CDR Link

1. Determine the status of CDR links.  
Enter `status cdr-link` and make sure that the CDR links are not busied out for maintenance. If the link is down, continue to the next step.
2. Where does the CDR link connect to?  
Enter `display system-parameters features` and find out the destinations of CDR links. Continue to the next step.
3. Enter `status data extension` and verify whether the data extension is in the *in-service/idle* state. If the data extension is not available, look for the extension number in the **Alt Name** field of the Error Log and see [XXX-BD \(Common Port Circuit Pack/Media Module\)](#) for resolutions.
4. Is the external CDR output device available?  
Make sure that the CDR output device is on-line and ready for service. Check the physical connectivity between Data Module and the CDR output device.
5. If the problem is not found in the above steps, check the C-LAN board for any problems. For description about system port and its connectivity, see [CLAN-BD \(Control LAN Circuit Pack\)](#).

When restoring the CDR link it is necessary to execute maintenance test on different objects that comprise the CDR link. It is recommended that you busyout the CDR link before trying to restore the link. When the CDR Link is busied out, then every CDR Link maintenance action is deactivated, and interference to tests of other MOs is prevented.

## Error log entries and recommended actions

Table 216: PRI-CDR Error Log Entries

| Error Type | Aux Data | Associated Test                                 | Alarm Level             | On/Off Board | Recommended Action                               |
|------------|----------|-------------------------------------------------|-------------------------|--------------|--------------------------------------------------|
| 0 (a)      | 0        | Any                                             | Any                     | Any          | <code>test cdr-link primary   secondary</code>   |
| 18 (b)     | 0        | <code>busyout cdr-link primary secondary</code> | WRN                     | OFF          | <code>release cd-link primary   secondary</code> |
| 257 (c)    | Any      | Link Retry test (#215)                          | MIN <sup>1</sup><br>WRN | OFF          | <code>test cd-link primary   secondary 1</code>  |
| 513 (d)    |          |                                                 |                         |              | <code>test cdr-link primary   secondary</code>   |
| 1025 (e)   |          |                                                 |                         |              |                                                  |
| 1281 (f)   | Any      |                                                 |                         |              |                                                  |

1. Minor alarms may be downgraded to Warning alarms based on the value used in `set options`.

### Notes:

- a. **Error Type 0:** run the short test sequence first. If every test passes, run the long test sequence. Refer to each test's description, and follow its procedures.
- b. **Error Type 18:** the CDR link is busied out and the CDR link is torn down.
- c. **Error Type 257:** Link Retry test (#215) failed. An error was detected when setting up the link. See the preceding section [Procedures for Restoring the CDR Link](#) for resolution.
- d. **Error Type 513:** the CDR physical link is down for one of the following reasons:
  1. Cable to the CDR output device is disconnected.
  1. CDR output device is powered off.
  1. The data extension where the CDR output device connects to has been busied out or there is a scheduled daily interchange.
  1. Check the connectivity of wire and cable among wall jacket, data module, and the CDR output device.
  2. Enter `status data extension` and verify that the data extension of the CDR output device is in the in-service/idle state. If the data extension is not available, see [Procedures for Restoring the CDR Link](#) for resolution.
  3. Use `display system-parameters maintenance` to see the start time of daily maintenance.
  4. If the error occurs and is resolved during of daily maintenance, it can be ignored.

- e. **Error Type 1025:** the CDR output device is in an off-line state, (for example, due to paper jam or paper out for a printer device). The CDR link is torn down.
1. Check the CDR output device and act promptly to put it back to on-line state.
  2. Enter `test cdr-link primary | secondary` command to set up the CDR link.
- f. **Error Type 1281:** overflow of CDR records generated in the switch due to the heavy trunk traffic and low speed CDR output device. If both primary and secondary links are ON, the secondary link is torn down temporarily for two minutes to speed up the output process to the primary link. No action is necessary for this Error Type.

---

## Demand test descriptions and error codes

Investigate tests in the order presented. By clearing errors associated with the first test, errors generated from other tests may also be cleared. Click on the link to see the full description of the test, error codes, and recommended actions.

| Order of Investigation                     | Short Test Sequence | Long Test Sequence | D/ND           |
|--------------------------------------------|---------------------|--------------------|----------------|
| <a href="#">Link Tear Down Test (#213)</a> |                     | X                  | Destructive    |
| <a href="#">Link Retry Test (#215)</a>     | X                   | X                  | Nondestructive |

## PROC-SAN (Process Sanity Audits)

| MO Name in Log | Alarm Level | Initial Command to Run | Full Name of MO       |
|----------------|-------------|------------------------|-----------------------|
| PROC-SAN       | none        | none                   | Process Sanity Audits |

The Process Sanity Audits MO is responsible for monitoring the sanity of software processes in the system. If the Process Sanity Audits MO detects that a process has gone insane (does not respond to a sanity message within an allotted time period), the process will be restarted. If the Process Sanity Audits MO detects that multiple processes (or a single key process) do not respond to sanity messages within an allotted time period, a system recovery action will be initiated.

The Process Sanity Audits MO has no alarms and no tests. Certain errors are logged to the Error Log for information purposes only.

---

## Error log entries and recommended actions

**Table 217: PROC-SAN Error Log Entries**

| Error Type | Aux Data | Associated Test | Alarm Level | On/Off Board | Recommended Action |
|------------|----------|-----------------|-------------|--------------|--------------------|
| 0          | 0        | Any             | Any         | Any          | none               |
| 10 (a)     | 0        | none            | none        | none         | none               |
| 204 (a)    | any      | none            | none        | none         | none               |

Note:

- a. **Error Type 10, 204:** a system recovery action was taken because one or more software processes failed to respond to a sanity audit in a timely fashion. As a result of the recovery action, the system may have temporarily suspended service for a period of time surrounding the error.

# PS-RGEN (Power Supply Ring Generator)

G650

| MO Name in Log | Alarm Level | Initial Command to Run     | Full name of MO             |
|----------------|-------------|----------------------------|-----------------------------|
| PS-RGEN        | MAJ<br>MIN  | <i>test board location</i> | Power Supply Ring Generator |

The PS-RGEN maintenance object monitors the ringing voltage of each 655A power supply. The TN2312BP IPSI uses the ring detection circuit on the 655A to monitor ring voltage for the G650. When the TN2312BP IPSI is used in an MCC1 or SCC1, the ring detector on the tone clock monitors ringing.

When the G650 is equipped with two power supplies, the 655A power supply on the left (slot 0) is the primary power supply (master) and the 655A power supply on the right (slot 15) is the secondary power supply. In normal operation, the primary 655A provides ringing for the G650. If the primary 655A is unable to provide ringing to the G650 because it has failed or because of a command from the TN2312BP IPSI, the secondary 655A connects ringing to the backplane using an arbitration lead.

Normally the ring voltage LED (#5) on the left power supply is ON and the ring voltage LED on the right power supply is OFF. This changes momentarily when the ringer interchange test is run. The ring voltage LED will only remain lit on the right power supply when there is a power supply failure of the left hand supply or the left hand supply is removed.

Only one 655A power supply provides ringing voltage to the backplane. The other power supply ring voltage output is isolated from the backplane through a relay contact.

Refer to [Figure 66: G650 Cabinet Environmental Hardware Components](#) for further information.

---

## Error log entries and recommended actions

**Table 218: PS-RGEN Error Log Entries 1 of 2**

| Error Type | Aux Data | Associated Test                         | Alarm Level             | On/Off Board | Recommended Action                                                  |
|------------|----------|-----------------------------------------|-------------------------|--------------|---------------------------------------------------------------------|

| 1025       | 64<br>65 | Ring generator interchange test (#1539) | MAJ<br>MIN              | ON           | test environment location<br>test board location |
|            |          |                                         |                         |              | <b>2 of 2</b>                                    |

1. This is a minor alarm if there is a redundant power supply, and a major alarm if there is only one power supply.

## Notes:

- a. **Error Type 1:** ring generator interchange failed. Run **test environment long**. Run **test board long**. Follow the repair procedures for any test failures.
- b. **Error Type 257:** ring voltage not detected on backplane.
- c. **Error Type 513:** ring generator operational status failure. Aux Data values give description (values may be added together).

| Aux Data | Description                                                                                                  |
|----------|--------------------------------------------------------------------------------------------------------------|
| 1        | Overload                                                                                                     |
| 2        | Shorted                                                                                                      |
| 4        | Internal fault                                                                                               |
| 8        | Commanded off                                                                                                |
| 16       | When redundant power supplies are present, the standby ring generator (slot 15) is providing ringing voltage |
| 32       | No ringing voltage on backplane                                                                              |

---

## Demand test descriptions and error codes

Investigate tests in the order presented. By clearing errors associated with the first test, errors generated from other tests may also be cleared. Click on the link to see the full description of the test, error codes, and recommended actions.

| Order of investigation                                  | Short test sequence | Long test sequence | D/ND           |
|---------------------------------------------------------|---------------------|--------------------|----------------|
| <a href="#">Ring Generator Interchange Test (#1539)</a> |                     | X                  | Nondestructive |
| <a href="#">Ring Generator Status Test (#1540)</a>      | X                   | X                  | Nondestructive |

## RANL-STA (Remote Analog Line (Station) Port)

| MO Name in Log | Alarm Level | Initial Command to Run               | Full Name of MO         |
|----------------|-------------|--------------------------------------|-------------------------|
| RANL-STA       | MIN         | <code>test port location long</code> | Remote Analog Line Port |
|                | WRN         | <code>test port location</code>      |                         |

The RANL-STA MO maintains the circuitry associated with a port which has been translated as analog station.

Failures of the neon message waiting lamp power and the common ringing application circuitry are reported as part of common port circuit pack errors. See errors 1281 and 1793 in [XXX-BD \(Common Port Circuit Pack/Media Module\)](#).

---

## Ringling Caused by Maintenance Testing

Test #48 may cause some terminal equipment to ring briefly during daily maintenance. If this ringing disturbs the customer or the terminal equipment, disable it in the **Tests** field of the `change station extension` screen. This also disables Test 35 on that station.

---

## Error log entries and recommended actions

Table 219: RANL-STA Error Log Entries 1 of 2

| Error Type | Aux Data                | Associated Test                        | Alarm Level | On/Off Board | Recommended Action                     |

|            |                         |                                        |             |              | <i>1 of 2</i>                          |

**Table 219: RANL-STA Error Log Entries 2 of 2**

| Error Type | Aux Data | Associated Test                | Alarm Level          | On/Off Board | Recommended Action                  |
|------------|----------|--------------------------------|----------------------|--------------|-------------------------------------|
| 513 (e)    |          | Ringing Application Test (#48) | WRN                  | OFF          | <code>test port location r 2</code> |
| 769        |          | Port Diagnostic Test (#35)     | MIN WRN <sup>1</sup> | ON           | <code>test port location r 2</code> |
| 2817 (f)   |          | Hyperactive                    | MIN                  | OFF          |                                     |
|            |          |                                |                      |              | <b>2 of 2</b>                       |

1. Minor alarms on this MO may be downgraded to Warning alarms based on the values used in `set options`.

**Notes:**

- a. **Error Type 0:** run the short test sequence first. If every test passes, run the long test sequence. Refer to each test's description, and follow its procedures.
- b. **Error Type 1:** inline errors, can only be resolved over time.
  - 1 Aux Data 40960 indicates that too many simultaneous incoming ringing attempts were made on this board. Only 4 ports on a board may ring simultaneously. A 5th incoming call will cause an inline error from the board.
  - 1 Aux Data 40975 indicates that the terminal equipment was on-hook when ring-tip was detected during ringing. This usually indicates a failure in the terminal equipment or the type of terminal has a low ringer impedance. Call the terminal equipment and verify that the terminal rings. If the terminal does not ring, then replace it. Otherwise, enter the `test port location` command, and follow the procedure for Test #48.
  - 1 Aux Data 40977 indicates that terminal equipment was not connected when ringing was attempted. Run the short test using the `test port location` command, and follow the procedure for the results of Test #48.
- c. **Error Type 15:** A software audit error that does not indicate hardware malfunction. Run the short test sequence, and investigate associated errors.
- d. **Error Type 257:** An inline error and can only be resolved over time. This error indicates that ringing voltage is absent. If only one analog circuit pack in the system has this problem, then replace the circuit pack. If only analog circuit packs on a particular carrier have this error, then the ringing generator may not be connected to this carrier. If analog circuit packs on many carriers have this error, then it is probably a problem with the ringing generator.
- e. **Error Type 513:** Test #48 may cause some terminal equipment to ring briefly during daily maintenance. If this disturbs the customer or the terminal equipment, disable it by setting the **Tests** field on the `change station extension` screen to **n**. On some software releases, this will also disable Tests #7 and 35.

- f. **Error Type 2817:** the endpoint caused a large number of control channel messages to be sent to the switch within a short period of time (50 or more CCMS uplinks within 10 seconds). The station will be taken out-of-service for 30 seconds due to the hyperactivity. This may be completely normal during heavy traffic periods.

---

## Demand test descriptions and error codes

Investigate tests in the order presented. By clearing errors associated with the first test, errors generated from other tests may also be cleared. Click on the link to see the full description of the test, error codes, and recommended actions.

| Order of Investigation                            | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|---------------------------------------------------|---------------------|--------------------|-------------------|
| <a href="#">Port Diagnostic Test (#35)</a>        | X                   | X                  | ND                |
| <a href="#">ONS Ringer Application Test (#48)</a> | X                   | X                  | ND                |
| <a href="#">Port Audit And Update Test (#36)</a>  | X                   | X                  | ND                |

1. D = Destructive; ND = Nondestructive

## RC-BD (Radio Controller Board)

| MO Name in Log | Alarm Level | Initial Command to Run          | Full Name of MO        |
|----------------|-------------|---------------------------------|------------------------|
| RC-BD          | MIN         | <i>test board location long</i> | Radio Controller Board |
|                | WRN         | <i>test board location</i>      |                        |

The RC-BD maintenance object is inserted into the system whenever the TN789 RC circuit pack is administered and physically inserted into a slot. Each RC circuit pack is maintained as a separate MO.

## Error log entries and recommended actions

Table 220: RC-BD Error Log Entries 1 of 2

| Error Type | Aux Data | Associated Test                                | Alarm Level | On/Off Board | Recommended Action              |
|------------|----------|------------------------------------------------|-------------|--------------|---------------------------------|
| 0 (a)      | 0        | Any                                            | Any         | Any          | <i>test board location</i>      |
| 1 (b)      | 0        | Circuit pack removed or SAKI Test failed (#53) | MIN         | ON           | <i>test board location</i>      |
| 18 (c)     | 0        | <i>busyout station extension</i>               | WRN         | OFF          | <i>release board loc</i>        |
| 23 (d)     |          |                                                | WRN         | OFF          |                                 |
| 125 (e)    |          |                                                | WRN         | ON           |                                 |
| 130 (f)    |          |                                                | WRN         | OFF          |                                 |
| 257 (g)    |          | Control Channel Looparound Test (#52)          | MIN         | ON           | <i>test board location r 20</i> |
| 513 (h)    |          |                                                | MIN         | ON           | <i>test board location r 2</i>  |
| 769 (i)    |          |                                                |             |              |                                 |

| 2817 (q)   |          | RC Data Relations Audit       | WRN         | OFF          |                    |
| 3073 (r)   |          |                               | MIN         | ON           |                    |
| 3329 (s)   |          |                               | MIN         | OFF          |                    |
| 3585 (t)   |          |                               | WRN         | OFF          |                    |
| 3841 (u)   |          |                               |             |              |                    |
|            |          |                               |             |              | <b>2 of 2</b>      |

## Notes:

- a. **Error Type 0:** run the short test sequence first. If every test passes, run the long test sequence. Refer to each test's description, and follow its procedures.
- b. **Error Type 1:** the circuit pack stopped functioning or has been physically removed from the system. The alarm is logged approximately 11 minutes after removal of the circuit pack or failure of the SAKI Sanity Test (#53).  
  
Check for the physical presence of the circuit pack in the slot indicated by the alarm. If the circuit pack is absent, insert one of the proper type. If the circuit pack is present and its red LED is lit, see LED alarms without Alarm Log entry or with Error Type 1 in *LED Descriptions for Avaya Aura™ Communication Manager Hardware Components (03-602804)*.
- c. **Error Type 18:** the circuit pack has been busied out. Release the circuit pack using **release board location**.

- d. **Error Type 23:** the circuit pack has been logically administered but not physically installed. The alarm should clear when the circuit pack is installed.

If the circuit pack is already installed:

1. Run `test board location long` and look at any test failures or Error Codes generated.
2. If the test does not clear error 23, then execute `reset board location` and run the long test again.

If the reset/test does not clear error 23, replace the circuit pack.

- e. **Error Type 125:** wrong circuit pack has been physically inserted into a slot administered for an RC circuit pack.
- f. **Error Type 130:** an RC circuit pack has been physically inserted into a slot for which it has not been administered
- g. **Error Type 257:** transient communication problems between the switch and this circuit pack. Execute `test board location` and refer to the repair procedures for the [Control Channel Looparound Test \(#52\)](#).
- h. **Error Type 513:** This error indicates an on-board hardware failure. The system will continuously test the circuit pack and report the results approximately every 10 minutes. If the hardware problem is resolved, the alarm should clear in approximately 30 minutes. If the alarm does NOT clear in 30 minutes, then the circuit pack should be replaced.
- i. **Error Type 769:** this error can be ignored, but look for other errors on this circuit pack.
- j. **Error Type 1025:** this error is not service-affecting, and no action is required
- k. **Error Type 1281:** Execute `test board location` and refer to the repair procedures for [RC NPE Allocation Test \(#1336\)](#)
- l. **Error Type 1537:** this error occurs when an excessive number of up-link messages have been received by the circuit pack. Switch software will take the circuit pack out of service and alarm the circuit pack. Switch software will periodically (every 15 minutes) put the circuit pack back in service. If the problem still exists, the circuit pack will again be taken out of service. If the circuit pack does not exhibit the problem for a certain amount of time, the alarm will be resolved and the circuit pack will be left in service.
- m. **Error Type 1793:** this error occurs if the RC detects a DECT protocol error.
- n. **Error Type 2049:** Execute `test board location` and refer to the repair procedures for [RC NPE Port Loop Test \(#1316\)](#)
- o. **Error Type 2305:** this error indicates a firmware checksum error.
- p. **Error Type 2561:** this error indicates a firmware upgrade operations error.
- q. **Error Type 2817:** Execute `test board location` and refer to the repair procedures for [RC Hardware Translation Audit \(#1317\)](#).
- r. **Error Type 3073:** this error indicates loss of SYSCLOCK.
- s. **Error Type 3329:** this error indicates loss of HSCLOCK.

- t. **Error Type 3585:** this error indicates a WT firmware upgrade server error.
- u. **Error Type 3841:** this error indicates the RC circuit pack received an inconsistent downlink message (bad header, bad port number, bad data, etc.) over the Control Channel. This error is logged only.

---

## Demand test descriptions and error codes

Investigate tests in the order presented. By clearing errors associated with the first test, errors generated from other tests may also be cleared. Click on the link to see the full description of the test, error codes, and recommended actions.

| Order of Investigation                                | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|-------------------------------------------------------|---------------------|--------------------|-------------------|
| <a href="#">Control Channel Looparound Test (#52)</a> | X                   | X                  | ND                |
| <a href="#">RC Hardware Translation Audit (#1317)</a> | X                   | X                  | ND                |
| <a href="#">NPE Audit Test (#50)</a>                  |                     | X                  | ND                |
| <a href="#">RC NPE Port Audit Test (#1315)</a>        |                     | X                  | D                 |
| <a href="#">RC NPE Port Loop Test (#1316)</a>         |                     | X                  | D                 |
| <a href="#">RC Tone Loopback Test (#1343)</a>         |                     | X                  | D                 |
| <a href="#">RC NPE Allocation Test (#1336)</a>        | X                   | X                  | ND                |
| <a href="#">Clear Error Counters Test (#270)</a>      | X                   | X                  | ND                |

1. D = Destructive; ND = Nondestructive

## RDIG-STA (Remote Digital Station)

| MO Name in Log | Alarm Level | Initial Command to Run                  | Full Name of MO        |
|----------------|-------------|-----------------------------------------|------------------------|
| RDIG-STA       | MIN         | <code>test station location long</code> | Remote Digital Station |
|                | WRN         | <code>test station location</code>      |                        |

The RDIG-STA MO maintains the circuitry associated with a port which has been translated as a digital station (or DCP Console).

Remote Digital Station maintenance software provides maintenance for a port administered as a digital station on the circuit pack. This strategy covers the inline errors log, initialization tests, periodic tests, craft-demanded tests, and alarm resolution and escalation. Each port, translated as a digital station on a digital line board, is running as a separate MO (RDIG-STA) of this type. Fault conditions discovered on one MO may or may not indicate faults on other MOs of the same type.

Maintenance testing for the port circuitry on the combo blade circuit packs is handled by on-board firmware and server-controlled tests. Maintenance software queries the firmware for error and alarm information, status, and test results. Firmware automatically reports inline error conditions, which results in server-controlled testing.

There are instances where the service state of a station is mentioned. The different service states that apply to a remote digital line station are as follows:

|                   |                                                                                                                                                                                                                                                                                                                                 |
|-------------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Out-of-Service    | The port, and thus the station, have been removed from service. Busyout puts the port in the out-of-service state.                                                                                                                                                                                                              |
| Ready-for-Service | The port on the circuit pack has been put into service, but the voice terminal has not yet established signaling communications with the port.                                                                                                                                                                                  |
| In-Service        | The voice terminal has established signaling communications with the port, and the system is ready to process calls to and from that station. A terminal in the ready-for-service state will progress to the in-service state if it is functioning normally. It can also be forced into the in-service state by going off-hook. |

---

## Downloading of Terminal Parameters

### Programmable Terminals

The following information describes how maintenance software interacts with terminal parameter downloading.

## Terminal Types

1. 84xx multi button digital voice terminals (8403D01A, 8410B, 8410D02A, 8434D01A) with optional expansion module.
2. 603A1 and 603D1 Callmaster terminals for telemarketing applications.
3. 302B1 and 302C1 attendant console.

## Downloadable Terminal Parameters

The following parameters are downloaded to programmable terminals:

**Table 221: Parameters Downloadable to Programmable Terminals**

| Parameter                                                        | Scope                         | Terminal              |
|------------------------------------------------------------------|-------------------------------|-----------------------|
| International Flags (A-/mu-law, display mode, DLI voltage level) | System level                  | 84xx<br>603x<br>302B1 |
| Primary Levels (transmission and sidetone)                       | System level                  | 84xx<br>603x<br>302B1 |
| Adjunct Levels (transmission and sidetone)                       | System level                  | 84xx                  |
| Handset Expander Option                                          | System level                  | 84xx                  |
| Administrable Options (speakerphone and mute button)             | Per-terminal                  | 84xx                  |
| Administrable Softkeys                                           | Per-terminal,<br>system level | 8410D<br>8434D        |
|                                                                  |                               |                       |

## Nonvolatile Memory

Nonvolatile memory stores downloadable parameters in programmable terminals. Once the terminal is downloaded, it is not necessary to download it again, even if power is removed from the terminal. If nonvolatile memory fails with power still present, the terminal reverts to its default factory settings except for its A-law/mu-law companding settings which are stored in RAM. If power is removed after the nonvolatile memory fails, the terminal reverts to its factory default settings.

### Note:

The mu-law companding mode is assigned as a default setting at the factory. For the United States, a programmable terminal can place calls even though it has not been downloaded from the system.

## Download Actions

There are several different scenarios which causes a terminal to be downloaded. These can occur as part of background maintenance activity or on demand from the SAT (System Access Terminal) or from a station.

For the background actions described below, the terminal downloads automatically if a download retry flag for the terminal is set in software. This flag is set at the time translation is loaded at boot time, when the translation that affects the parameters of a terminal is changed as part of system administration actions, or when a port is inserted in software as a result of board insertion or translation change.

### Automatic Download Actions

#### 1. System Reboot/Restart

A global download action is initiated when periodic maintenance tests begin after a system reboot/restart, regardless of whether the parameters have been downloaded previously.

#### 2. Periodic tests

If the download flag is still set when periodic tests are run on a terminal, a download action occurs. This action is required in case a terminal could not be downloaded previously, because the terminal was off-hook when the:

- 1 system first booted
- or
- 1 translations associated with downloadable parameters were changed.

### Note:

It may take more than an hour for periodic tests to reach the terminal that needs to be downloaded.

### 3. Terminal Administration

A downloadable terminal is *automatically* downloaded when translation changes associated with downloadable parameters are made as part of system administration. As shown in the previous table, these changes can be for a specified terminal or may be system-wide. If the change is for a system-level parameter, a background global update request must be submitted to download every programmable terminal.

**Note:**

This global update may take more than an hour for a system with several thousand programmable terminals.

### 4. Port Insertion

Whenever maintenance software initiates a request to place a port into service, a terminal download action is begun on that terminal, if that terminal is programmable. This port insertion action occurs under the following circumstances:

- 1 A digital line circuit pack that is physically inserted into the system and has ports currently administered for programmable terminals.
- 1 A station port is added to the system by `add station` or `change station`.
- 1 A TTI port is activated.

### 5. Audits

As part of periodic maintenance, the Hardware Status Audit test queries programmable terminals to determine which levels and/or options are being used. If the reported values are not equal to the administered values, the system will initiate a terminal download action; however, this audit does NOT check the parameters used for softkeys.

### 6. Activation of TTI

A terminal is downloaded automatically when it is activated using the TTI (Terminal Translation Initialization) feature. Therefore, no special user actions are required for TTI.

**Note:**

Plugging the station cord into a terminal does not automatically cause the terminal to be downloaded. If this terminal has factory defaults or if the terminal has been previously downloaded with parameters different than those desired, use one of the demand download actions described below to download the terminal.

## Demand Download Actions

### 1. Busyout/Release Command

A maintenance demand busyout/release request for a station will cause the terminal to be downloaded regardless of its previous download status.

### 2. Feature Access Code

A Refresh Terminal Parameters Feature Access Code can be used to request a terminal download action. When this code is followed by a “#”, the programmable parameters for the current terminal are downloaded when the terminal goes on-hook. When this code is followed by an extension, the programmable parameters for the specified station are downloaded.

This Refresh Terminal Parameters Feature Access Code is assigned on the third page of the **change feature-access-codes** screen.

A confirmation is returned if the download request is accepted. A busy tone is returned if the request is made from a different station when the target station is off-hook.

As a result of an entry of a Refresh Terminal Parameters Facility Access Code, the first three green call appearance LEDs on the 84xx 603x terminal are turned on for three seconds, if the station was successfully downloaded. This is not true for the 302B1 terminal.

There is no visible display on a station for the other background or demand download actions. As described below, use **status station** and **status attendant** to check the download status of a specified terminal.

## Status of Parameter Downloads

The **status station** and **status attendant** screens display the current download status of individual 84xx, 603, and 301B1 terminals in the **Download Status** field. The possible download states are:

| Status         | Terminal Download State                                                                                                                                                                                                                        |
|----------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| Complete       | The terminal successfully downloaded sometime in the past.                                                                                                                                                                                     |
| Pending        | The system is waiting to download the terminal. This may require the execution of a background periodic test, which could take more than an hour. As previously described, demand download can also be used to initiate an immediate download. |
| Not Applicable | Not a programmable terminal.                                                                                                                                                                                                                   |

Possible reasons for no terminal download include:

- 1 Terminal is off-hook.
- 1 Terminal detected a bad checksum.
- 1 Terminal detected a bad or missing EEPROM (refer to the Error Log).
- 1 Terminal is busy programming data from a previous PROGRAM message.
- 1 Terminal is in the Programming Disabled state.
- 1 Terminal is in the Local Program Options mode.
- 1 Terminal is disconnected or out of service (use **status station**).

**Table 222: RDIG-STA Error Log Entries**

| Error Type | Aux Data         | Associated Test              | Alarm Level | On/Off Board | Recommended Action            |
|------------|------------------|------------------------------|-------------|--------------|-------------------------------|
| 0 (a)      | 0                | Any                          | Any         | Any          | <i>test port location</i>     |
| 1 (b)      | 1 – 20,<br>40987 |                              | WRN         | OFF          |                               |
| 18 (c)     | 0                | <i>busyout port location</i> | WRN         | OFF          | <i>release port location</i>  |
| 257 (d)    | 40971            |                              |             |              |                               |
| 513 (e)    | 0                | Digital Station Audits #17)  | WRN         | OFF          | <i>test port location r 6</i> |
| 767 (f)    | 40964            |                              | WRN         | OFF          |                               |
| 769 (g)    | 40963<br>40988   |                              | WRN         | OFF          |                               |
| 1025 (h)   |                  |                              | WRN         | OFF          |                               |
| 1281       | Any              | Digital Station Audits (#17) | WRN         | OFF          | <i>test port location r 4</i> |
| 1537 (i)   | 40968            |                              | WRN         | OFF          |                               |
| 2304 (j)   |                  |                              |             |              |                               |
| 2305 (k)   | 32770<br>40967   |                              |             |              |                               |
| 2817 (l)   |                  | Hyperactive                  | MIN         | OFF          |                               |
| 3840 (m)   | 40965<br>40989   |                              |             |              |                               |
| 3841 (n)   | 41029            |                              |             |              |                               |

Notes:

- a. **Error Type 0:** run the short test sequence first. If every test passes, run the long test sequence. Refer to each test's description, and follow its procedures.
- b. **Error Type 1 with Aux Data 40987:** could be caused by a noisy port or link. This is an off-board problem detected by the port circuit. Check for defective wiring, a defective voice terminal, or move the voice terminal closer to the switch (in terms of feet of wire from the jack to the switch). If the problem persists, replace the circuit pack. Once the problem has been resolved, the alarm disappears after a predetermined amount of time.

**Error Type 1 with Aux Data 1-20:** occurs when at least 15 off-board problems have been detected with the link to the terminal. When an error with the link is detected, an on-board counter is incremented.

The user could experience a noisy port or link. This is an off-board problem detected by the port circuit. Check for defective wiring, a defective voice terminal, or move the voice terminal closer to the switch (in terms of feet of wire from the jack to the switch). If the problem persists, replace the circuit pack. Once the problem has been resolved, the alarm disappears after a predetermined amount of time.
- c. **Error Type 18:** the port in question is busied out by maintenance personnel. Make sure the port is released from busyout by **release port location**.
- d. **Error Type 257:** Indicates problems transmitting to the voice terminal, which can be caused by defective wiring. Defective wiring can cause varying degrees of problems on different types of sets.
- e. **Error Type 513:** The result of an ID Request failure to respond to the digital endpoint audit.
- f. **Error Type 767:** An inline event produces this Error Type when a favorable response is received from running the [Digital Line Electronic Power Feed Test \(#11\)](#). No action is necessary. This alarm will be resolved with the passing of time.
- g. **Error Type 769 with Aux Data 40963:** The result of an unfavorable response to the [Digital Line Electronic Power Feed Test \(#11\)](#).

**Error Type 769 with Aux Data 40988:** the EPF/PTC circuit has been turned off due to an overcurrent condition.

Once the problem has been resolved, it may take up to one hour for the alarm to clear. If the problem cannot be resolved by one of the steps above, replace the circuit pack.
- h. **Error Type 1025:** problem with the voice terminal EEPROM. When the voice terminal is repaired the alarm will be resolved with the passing of time.
- i. **Error Type 1537:** there is a problem with the link to the voice terminal. This can be ignored if no user complaints are received. Otherwise, make sure the voice terminal is connected, check for defective wiring, check for a defective voice terminal, and move the voice terminal to a jack that is closer to the switch (in terms of feet of wiring between the jack and the switch). If the problem persists, replace the circuit pack. Once the problem has been resolved, the alarm disappears after a predetermined amount of time.
- j. **Error Type 2304:** internal system error. No action is necessary.

- k. **Error Type 2305 with Aux Data 32770:** the station went off-hook while it was in the ready-for-service state. Use the `status station` command to determine the state of the station. The off-hook should have moved the station to ready-for-service. No action is necessary.

**Error Type 2305 with Aux Data 40967:** an off-board warning was generated due to a problem with the link to the voice terminal. This can be ignored if no user complaints are received. Otherwise, make sure the voice terminal is connected, check for defective wiring, check for a defective voice terminal, and move the voice terminal to a jack that is closer to the switch (in terms of feet of wiring between the jack and the switch). If the problem persists, replace the circuit pack. Once the problem has been resolved, the alarm disappears after a predetermined amount of time.

- l. **Error Type 2817:** the endpoint caused a large number of control channel messages to be sent to the switch within a short period of time (50 or more CCMS uplinks within 10 seconds). The station will be taken out-of-service for 30 seconds due to the hyperactivity. This may be completely normal during heavy traffic periods.
- m. **Error Type 3840 with Aux Data 40965:** no terminal is connected to the board. No maintenance action is required. This is also the code that is generated when the link between the circuit pack and the voice terminal is successfully reset. No action is necessary.

**Error Type 3840 with Aux Data 40989:** Indicates an uplink message has been logged indicating that the Electric Power Feed (EPF) is on with no load on it. No action is necessary.

- n. **Error Type 3841:** the circuit pack's message buffer is full. This may be caused by having many display phones with heavy traffic connected to the circuit pack. No action is necessary.

---

## Demand test descriptions and error codes

Investigate tests in the order presented. By clearing errors associated with the first test, errors generated from other tests may also be cleared. Click on the link to see the full description of the test, error codes, and recommended actions.

| Order of Investigation                                        | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|---------------------------------------------------------------|---------------------|--------------------|-------------------|
| <a href="#">Digital Line Electronic Power Feed Test (#11)</a> |                     | X                  | ND                |
| <a href="#">Digital Station Lamp Update (#16)</a>             | X                   | X                  | ND                |
| <a href="#">Digital Station Audits Test (#17)</a>             | X                   | X                  | ND                |

1. D = Destructive; ND = Nondestructive

## REM-OFF (Remote Office)

| MO Name in Log | Alarm Level | Initial Command to Run                                      | Full Name of MO |
|----------------|-------------|-------------------------------------------------------------|-----------------|
| REM-OFF        | MIN<br>WRN  | <code>ping node-name node-name   ip-address location</code> | Remote Office   |

An instance of this MO (REM-OFF) is associated with every Remote Office box that is administered on the switch. This MO monitors keep-alive and periodic PING test failures.

---

## Error log entries and recommended actions

Table 223: REM-OFF Error Log Entries

| Error Type              | Aux Data | Associated Test | Alarm Level | On/Off Board | Recommended Action                                                         |
|-------------------------|----------|-----------------|-------------|--------------|----------------------------------------------------------------------------|
| 1 <a href="#">(a)</a>   |          |                 | MIN         | OFF          | <code>ping node-name node-name</code><br><code>ping ip-address addr</code> |
| 257 <a href="#">(b)</a> |          |                 | Log only    | OFF          | <code>ping node-name node-name</code><br><code>ping ip-address addr</code> |

Notes:

- a. **Error Type 1:** a PING test to the Remote Office has failed and a MINOR alarm has been raised. When this error is logged, as many as 26 endpoints associated with that Remote Office and several H.323 signaling groups could be out of service.
- b. **Error Type 257:** The response to a keep-alive update request exceeded the time limit for an endpoint. The error is a log-only error. It is not possible to determine which entity has failed.

The aux data associated with this error indicates whether the endpoint that failed to respond was a DCP, Analog, or Signaling Group type:

- 1 1096 = Analog Line
- 1 1095 = DCP Line
- 1 6179 = H.323 Signaling Group

---

## Demand test descriptions and error codes

There are no demand tests for REM-OFF. Use `ping ip-address` or `ping node-name` to ping the Remote Office.

## RING-GEN (Analog Ring Generator)

| MO Name in Log | Alarm Level | Initial Command to Run                 | Full Name of MO       |
|----------------|-------------|----------------------------------------|-----------------------|
| RING-GEN       | MAJ         | <code>test environment location</code> | Analog Ring Generator |

Analog phones must be provided with a voltage that allows them to ring. The Analog Ring Generator provides the ringing voltage for every analog phone associated with a given cabinet. In a multicarrier cabinet, the ring generator resides in the power distribution unit. It is protected by a fuse located next to the main circuit breaker on the front of the unit. In single-carrier cabinets, the ring generator is part of the WP-91153 power supply.

Failure of the ring generator results in loss of ringing on analog phones. Ringing on digital and hybrid phones is not affected.

The ringing voltage is monitored by the Tone-Clock circuit pack. In a port network with duplicated Tone-Clocks, the active Tone-Clock performs this function. In a PN made up of single-carrier cabinets, the Tone-Clock monitors the ringing voltage of only the carrier where it resides.

The TN2036 Voltage Range circuit pack provides easy access for testing the various voltages on the backplane pins.

---

## Error log entries and recommended actions

**Table 224: RING-GEN Error Log Entries**

| Error Type            | Aux Data | Associated Test             | Alarm Level | On/Off Board | Recommended Action                         |
|-----------------------|----------|-----------------------------|-------------|--------------|--------------------------------------------|
| 0 <a href="#">(a)</a> | 0        | Any                         | Any         | Any          | <code>test environment location</code>     |
| 1                     |          | Ring Generator Query (#118) | MAJ         | ON           | <code>test environment location r 3</code> |

Note:

- a. **Error Type 0:** run the short test sequence first. If every test passes, run the long test sequence. Refer to each test's description, and follow its procedures.

## Demand test descriptions and error codes

Investigate tests in the order presented. Click on the link to see the full description of the test, error codes, and recommended actions.

| Order of Investigation                                                       | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |

1. D = Destructive, ND = Nondestructive

## RMC-ENV (Power/Fan Sensors)

G600 only

| MO Name in Log | Alarm Level | Initial Command to Run | Full Name of MO   |
|----------------|-------------|------------------------|-------------------|
| RMC-ENV        | MAJ         | test environment       | Power/Fan Sensors |

The AC Power Supply (650A) for a G600 media gateway (Rack-Mounted Cabinet - RMC) supports one alarm lead that indicates the state of both the power and fan. The cabinets use variable-speed fans to reduce noise. The power unit contains thermal speed control. A 3-pin connector on the variable-speed fan assembly accepts variable input power to control its fan speed and power its alarm circuitry.

[Table 225: LED and Alarm Conditions](#) shows the LED and alarm conditions.

**Table 225: LED and Alarm Conditions**

| Condition                           | LED Status         | Alarm State | Fan/Power Alarm                     |
|-------------------------------------|--------------------|-------------|-------------------------------------|
| Normal                              | Red off, amber on  | Open        | Normal                              |
| No input power                      | Red off, amber off | Closed      | No input power                      |
| DC output not present (except neon) | Red on, amber off  | Closed      | DC output not present (except neon) |
| Fan alarm                           | Red on, amber on   | Closed      | Fan/Power alarm                     |

### Fan Removal and Replacement

You can remove the fan assembly while the system is running, but you must replace the new assembly within 60 seconds to avoid a thermal overload.

1. Place the new fan assembly close to the G600.
2. Loosen the thumb screws on the fan assembly, and pull it straight out (unplug it) as shown in [Figure 64: Fan Removal](#). The power for the fan automatically disconnects when the assembly is unplugged.
3. Plug in the new fan assembly. The power for the fan automatically connects when the fan assembly is plugged in.
4. Tighten every thumb screw on the fan assembly.

**Figure 64: Fan Removal**

## Error log entries and recommended actions

**Table 226: RMC-ENV Error Log Entries**

| Error Type | Aux Data | Associated Test                       | Alarm Level | On/Off Board | Recommended Action |
|------------|----------|---------------------------------------|-------------|--------------|--------------------|
| 0 (a)      | 0        | Any                                   | Any         | Any          | test environment   |
| 1 (b)      | Any      | Cabinet Temperature Query test (#122) | MAJ         | ON           | test environment   |

Notes:

- a. **Error Type 0:** run the short test sequence first. If every test passes, run the long test sequence. Refer to each test's description, and follow its procedures.
- b. **Error Type 1:** the power-/fan-status lead indicates that a G600 media gateway's power supply has detected an alarm condition. The condition can be caused by the failure of any fan's or any power supply's output. If more than one G600 exists, every power-/fan-status lead is tied together. (The fan and power lead is an O-ring of every cabinet's status lead.) Since an error condition on a fan's or power supply's output could be the result of a temporary overload (e.g., during board insertion) or caused by the equipment's location (e.g., fan blockage), a single event may be an anomaly that eventually clears. However, a repeating condition causes a major alarm.

---

## Demand test descriptions and error codes

Investigate tests in the order presented. By clearing errors associated with the first test, errors generated from other tests may also be cleared. Click on the link to see the full description of the test, error codes, and recommended actions.

| Order of Investigation                                    | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |

Table 227: RSCL-PT Error Log Entries

| Error Type                | Aux Data | Associated Test | Alarm Level | On/Off Board | Recommended Action |
|---------------------------|----------|-----------------|-------------|--------------|--------------------|
| 130 ( <a href="#">a</a> ) |          |                 | WRN         | ON           |                    |

Notes:

- a. **Error Type 130:** The associated circuit pack has been removed or has been insane for > 11 minutes. To clear this error, make sure that the circuit pack is installed. If the circuit pack is installed, pull and re-insert the circuit pack to reset it.

## Demand test descriptions and error codes

There are no demand tests associated with RSCL-PT.

## S-SYN-BD (Speech Synthesis Circuit Pack)

| MO name  | Alarm Level | Initial Command to Run     | Full Name of MO               |
|----------|-------------|----------------------------|-------------------------------|
| S-SYN-BD | MIN<br>WRN  | <i>test board location</i> | Speech Synthesis Circuit Pack |

See [XXX-BD \(Common Port Circuit Pack/Media Module\)](#) for errors at the circuit-pack level.

See [S-SYN-PT \(Speech Synthesis Port\)](#) for related port information.

## S-SYN-PT (Speech Synthesis Port)

| MO name in Log | Alarm Level | Initial Command to Run      | Full Name of MO       |
|----------------|-------------|-----------------------------|-----------------------|
| S-SYN-PT       | MAJ<br>MIN  | <i>test port location 1</i> | Speech Synthesis port |
|                | WRN         | <i>test port location</i>   |                       |

The Speech Synthesis circuit pack provides four independent Speech Synthesis ports which may be connected to any of the voice time slots on the Time Division Multiplex (TDM) Bus. Each Speech Synthesis port consists of a speech synthesizer device (SSD) and is managed by a custom-coded programmable speech synthesizer (PSS) controller. The PSS controller is, in turn, controlled by the on-board microprocessor via a command interface specifically designed for this application. The PSS controller's main function is the orderly transfer of encoded speech from the speech vocabulary read-only memory (ROM) to the SSDs. The SSDs decode it and produce 64-kbps 5-255 PCM (Pulse Code Modulation) speech. The encoded speech is stored in up to 512 Kbytes of on-board ROM. In addition, each Speech Synthesis port has an associated dual-tone multifrequency receiver (DTMR) to receive touch-tone digits from a station set connected to the port via a voice time slot. The station set may be connected to the Speech Synthesis port through either a line or trunk circuit.

When there is an incoming call to a port, the "listen" network time slot is connected to the DTMF receiver input and the "talk" network time slot is connected to the SSD output. This enables the Speech Synthesis port to support speech synthesis features or touch-tone input with voice response features. Some of the features that use the Speech Synthesis port's capabilities include Leave Word Calling, Automatic Circuit Assurance, Automatic Wakeup (hotel-motel), and Do Not Disturb (hotel-motel).

The Speech Synthesis circuit pack supports different voice features than ones supported by the announcement circuit pack.

1. D = Destructive, ND = Nondestructive

## SEC-CDR (Call Detail Recording Link)

See [PRI-CDR \(Call Detail Recording Link\)](#) for maintenance procedures for SEC-CDR.

# SER-BUS (Serial Communication Bus)

G650

| MO Name in Log | Alarm Level | Initial command to run             | Full name of MO          |
|----------------|-------------|------------------------------------|--------------------------|
| SER-BUS        | MAJ         | <i>test environment location 1</i> | Serial Communication Bus |
|                | MIN         | <i>test environment location</i>   |                          |

Each port network of G650s has a Serial Bus that allows the TN231O2BP IPSI to communicate with the 655A power supplies. This Serial Bus uses 2 previously unused leads in the Universal Port Slot. SPARE3 (pin 055) now becomes serial data. SPARE4 (pin 155) now becomes serial clock. The serial communication bus is a two-wire bi-directional half-duplex bus that is provided on the backplane of the G650. The serial bus consists of a clock line and a data line. Data is transferred on the data line synchronously in bit-serial fashion a byte at a time. Communication on the serial bus is at speeds up to 100 kbits per second.

Older TDM/LAN cables did not have these 2 leads so the G650 required a new TDM/LAN cable. These 2 leads are not terminated on the TDM/LAN Terminators (AHF110). This is an open-collector bus where each power supply and each TN2312BP IPSI provide a pull-up resistor to +5VDC for each of the 2 Serial Bus leads. The bus will have logic pulses extending between 0V and 5V.

The TN2312BP IPSI in the A carrier will act as master of the serial bus and poll each of the power supplies based on their board address. Only a TN2312BP IPSI in the A carrier can be a bus master, even if a TN2312BP in carrier B is used for port network connectivity. Therefore, setting the TN2312BP in the A carrier or B carrier to be active will not clear a problem if the TN2312BP itself is the reason for the failure. The power supply's board address is derived from 4 board address leads in the power slot of the backplane. The G650 carrier addressing paddle card sets 3 of these 4 address leads for the power slot. A G650 can have a maximum of ten 655A power supplies on the serial bus (See [Figure 65: Wiring diagram for serial bus data and clock leads](#)).

**Note:**

The serial bus is provided only to a G650 equipped with TN2312BP IPSI circuit packs. The serial bus is not available on any other media gateway.

[Figure 66: G650 Cabinet Environmental Hardware Components](#) illustrates these components.

Figure 65: Wiring diagram for serial bus data and clock leads

**Figure 66: G650 Cabinet Environmental Hardware Components**

Use `status environment` to obtain:

- 1 Inlet temperature - 655A power supply sensor
- 1 Exhaust temperature - G650 carrier exhaust air sensor
- 1 Hot Spot temperature - 655A power supply sensor
  - The system generates a warning at 176° Fahrenheit (80° Celsius).
  - The power supply shuts down at 194° Fahrenheit (90° Celsius).
- 1 Power supply output voltage measurements, +5VDC, -5VDC, and -48VDC
- 1 Fan Control - The speed of the fans, either mid (normal) or high (fan failure or hot spot temperature limit exceeded).
- 1 Fan Alarm - Detection of a blocked or failed fan
- 1 Ring Status - OK, overload, shorted, or failed
- 1 Ring Control - Active, standby, disabled, off (shorted or failed)
- 1 Ringer Setting - 20Hz, 25Hz, or other
- 1 Ring Detection - Reports if power supply detects ring on the backplane ring leads

- 1 Source of input power - AC, DC, or both
- 1 Input power - Indicates the type of power currently in use, AC or DC
- 1 AuxSig signal status

**Note:**

If the TN 2312BP IPSI cot get data from the power supplies, the data entries for `status environment` will be dashed out.

Use `recycle carrier` to:

- 1 Shut off all voltage output temporarily
- 1 Shut off ringer voltage output temporarily

Use `clear error` to:

- 1 Clear the non-volatile source ID cause of the last shutdown
- 1 Clear the serial bus error and time-out counters

---

## Serial Bus Fault Detection and Isolation

Serial Bus faults can be caused by:

- 1 A defective circuit pack inserted into one of the G650 slots
- 1 Bent pins on the G650 backplane
- 1 Defective TDM/LAN bus cables
- 1 Power supply microcontroller failure
- 1 TN2312BP IPSI failure

It is possible that a circuit pack can cause a Serial Bus fault and still exhibit trouble-free operation. For example, insertions of any circuit pack into a G650 slot may bend the backplane pins and short two leads together. Or a circuit pack that doesn't use the Serial Bus could still have an on board short that shorts one of the Serial Bus leads. Since the Serial Bus is a shared resource that each circuit pack and power supply has access to, identification of the cause of a Serial Bus fault can be difficult.

Since the Serial Bus fault isolation procedure involves removing circuit packs and possibly disconnecting entire carriers, the procedure is extremely destructive to the port network that is being tested. If possible, arrange to perform this procedure at a time when traffic is minimal.

As circuit packs are removed or entire carriers are disconnected, any active calls terminating on those circuit packs or carriers will be dropped. If you have any hints about a particular circuit pack that may be causing the Serial Bus problem investigate those before performing this procedure (for example, look at any circuit packs that were inserted into the PN just before the Serial Bus problem appeared.) Also examine which power supplies the system is unable to show using `list configuration power-supply C` and concentrate your efforts on those carriers and their cabling.

 **CAUTION:**

When straightening or replacing backplane pins in a carrier, power to that carrier must be shut off. Failure to follow this procedure may result in damage to circuit packs and power supplies, and can be hazardous to the technician.

## Procedure 1

The procedure removes and reinserts port circuit packs (those in the purple slots) one or more at a time. Use this procedure for each port circuit pack in the port network until the problem is resolved or until all circuit packs in the port network have been tried.

If the Serial Bus problem is present when the circuit pack is inserted, but is resolved when the circuit pack is removed, either the circuit pack or the backplane pins in that slot are causing the problem. If the backplane pins are intact, replace the circuit pack. If some of the tests fail regardless of whether the circuit pack is inserted or removed, and the backplane pins are intact, the circuit pack is not the cause of the problem. In a multiple failure situation, the circuit pack could be one cause of the Serial Bus problem. However, other simultaneous failures might also be responsible for Serial Bus faults. In Procedure 2, an option of working either with one circuit pack at a time or with multiple circuit packs simultaneously is available. In view of this capability, determine the level of service interruption that will be acceptable during the procedure. If causing a disruption to all users in the port network is deemed permissible, large groups of circuit packs should be worked with in order to get the job done quickly. However, if large service disruptions are to be avoided, work with one circuit pack at a time. This option is slower, but it disrupts only the users of a single circuit pack.

Refer to the repair procedure steps given for [Serial Bus Status Test \(#1531\)](#).

## Procedure 2

Procedure 2 attempts to isolate the Serial Bus failure to a particular set of carriers. Only the circuit packs in selected carriers are checked. Procedure 2 is used if the preceding procedure fails, because it can help locate multiple circuit pack failures and failures of the carrier hardware itself. In this procedure, the TDM/LAN Cable Assemblies and TDM/LAN Bus terminators are replaced. If this action does not resolve the Serial Bus fault, the carriers are reconfigured so that

certain carriers are disconnected from the Serial Bus. This is done by moving the TDM/LAN Bus terminators (AHF110) on the carrier backplane. To terminate a Serial Bus at the end of a particular carrier, the Serial Bus cable that connects the carrier to the next carrier should be unplugged and replaced with the TDM/LAN Bus terminator. When the length of the Serial Bus is modified the A carrier TN2312BP IPSI circuit pack that is essential to the Serial Bus operation and Serial Bus maintenance must still be connected to the new shortened Serial Bus.

After cabling changes are made and verified, power must be restored to the port network. Circuit packs in carriers that are not part of the shortened bus are not inserted. As a result, these circuit packs are alarmed. Ignore these alarms for now. All alarms should be resolved when the cabinet is restored to its original configuration.

Procedure 2 is organized into two parts:

- 1 Part 1 attempts to clear the Serial Bus fault by replacing all the bus cabling and terminators within a port-network.
- 1 Part 2 attempts to isolate the fault to a particular carrier by extending the Serial Bus from the A carrier to additional carriers one at a time.

Refer to the repair procedure steps given for the [Serial Bus Status Test \(#1531\)](#)

---

## SIP-BCH (SIP B-Channel)

Session Initialization Protocol (SIP) signaling groups are similar in concept to ISDN PRI signaling groups. No physical hardware components make up the SIP B-channel or SIP D-channel objects discussed here, and no maintenance tests are run.

The SIP signaling group can be considered to be one D-channel that physically rides on a C-LAN port (IP-PROCR port on S8300 systems) and the IP network. Unlike ISDN D-channels, the SIP D-channel may come up and down on a call-by-call basis. The SIP D-Channel is actually a TCP/IP signaling channel. Layers 1 and 2 of this signaling channel can be monitored by IP PING testing.

SIP B-channels use Media Processor ports to carry the actual bearer. Any port of a media processor may serve an H.323 station or a SIP B-channel. Status information may exist for a specific SIP B-channel. A SIP B-channel may be busied out and released.

Errors are logged for *command* busyout conditions. Under normal conditions, the system automatically places SIP B-channels into or out of service when it receives a SIP signaling-group service state update. A *demand* busyout drops active calls.

---

## Error log entries and recommended actions

### SIP-BCH B-Channel Error Log Entries

| Error Type | Aux Data | Associated Test                 | Alarm Level | On/Off Board | Service State |
|------------|----------|---------------------------------|-------------|--------------|---------------|
| 18         | Any      | B-channel busied out by command | Warning     | off          | OOS           |

---

## System Commands

The following commands are available:

- 1 **busyout port location** - drops any active call on a specified SIP B-channel and reduces the trunk group's capacity by one. No physical piece of hardware is removed from service.
- 1 **release port location** - on a specific SIP B-channel, increases the trunk group's capacity by one. No physical piece of hardware is actually added to service.
- 1 **status trunk grp#/mem#** - displays the current status of the specific SIP B-channel, near and far end IP signaling addresses, near and far end H.245 addresses, tunneling status, and call-reference value for an active call.
- 1 **test port location** - displays No demand tests found for the specified physical object.

## SIP-SGRP (SIP Signaling Group)

| MO Name in Log | Alarm Level | Initial Command to Run                 | Full Name of MO     |
|----------------|-------------|----------------------------------------|---------------------|
| SIP-SGRP       | MIN<br>WRN  | <code>test signaling-group grp#</code> | SIP Signaling Group |

The SIP Signaling Group (SIP-SGRP) MO supports a signaling channel (D-channel) for SIP trunk connections. The MEDPRO TN802 and TN2302 circuit packs provide audio connectivity, working in concert with a C-LAN (TN799DP) circuit pack which provides control signaling to support a SIP connection.

### Note:

In S8300 systems, the audio connectivity is provided through the VoIP media modules within the S8300 system. The signaling is provided through the native NIC within the S8300 system.

The SIP signaling group (SIP-SGRP) is a signaling channel that physically resides on a C-LAN port (socket), or IP-PROCR in S8300 systems, and the IP network. Unlike ISDN D-channels, the SIP channel may actually come up and down on a call by call basis. The SIP channel is actually a TCP/IP signaling channel. Layers 1 and 2 of this signaling channel are monitored by IP PING testing.

---

## Error log entries and recommended actions

Table 229: SIP-SGRP Error Log Entries 1 of 2

| Error Type | Aux Data | Associated Test                           | Alarm Level | On/Off Board | Recommended Action                        |
|------------|----------|-------------------------------------------|-------------|--------------|-------------------------------------------|
| 0 (a)      | 0        | Any                                       | Any         |              | <code>test signaling-group grp#</code>    |

| 3841 - 3942 (o) |          |                                                     |             |              |                                        |
|                 |          |                                                     |             |              | <b>2 of 2</b>                          |

Notes:

- a. **Error Type 0:** Run the short test sequence first. If every test passes, run the long test sequence. Refer to each appropriate test's description, and follow its recommended procedures.
- b. **Error Type 1:** Failure of the C-LAN hardware (IP-PROCR in S8300 systems) carrying the signaling group channel.  
 To determine which C-LAN had been administered for this signaling group, find the near-end node name on the `signaling group` form, then find the C-LAN or IP-PROCR with the same node name on the `ip-interfaces` form.  
 Check for errors against the CLAN-BD MO.
- c. **Error Type 18:** The signaling group has been busied out by command. Release the signaling group, if appropriate, with `release signaling-group grp#`.
- d. **Error Type 257:** Tracks failures of the SIP signaling-group PING test. See [Signaling Group Ping Test \(#1387\)](#) for test failure information.
- e. **Error Type 513:** Tracks excessive round-trip delay of the SIP signaling-group PING test, if the round-trip delay exceeds 4 seconds. See [Signaling Group Ping Test \(#1387\)](#) for test failure information.
- f. **Error Type: 770:** Tracks excessive latency and packet-loss from background IP measurements collected by the Media Processor Board. Indicates that test packets sent from a media processor circuit pack to the far-end IP address specified on the `signaling-group` form have exceeded the IP latency and loss thresholds, as administered on the `system-parameters ip-options` form. Exceeding these thresholds indicates that the IP network may not be providing sufficient quality of service for

adequate transmission of voice. If the signaling group has been administered to enable BYPASS, then Error Type 1025 also occurs.

- g. **Error Type 1025:** the signaling group has been placed into a BYPASS condition because of IP network congestion. The signaling group accepts incoming calls, but every outgoing call is denied. The system routes these calls over a secondary route, if one has been administered.
- h. **Error Type 1281:** No medpro resources are in service to provide media connections for the trunk members of the signaling group.

Check for errors against the MEDPRO and MEDPROPT maintenance objects. This error causes all SIP B-channels to be in an out-of-service near-end state.
- i. **Error Type 1537:** The far end of the signaling group is not ready to handle audio bearer. If the other end of this signaling group is also a Communication Manager server, this error means the server on the other end does not have MEDPRO in-service for its signaling group.

This error places the SIP B-channels into an out-of-service far-end state.
- j. **Error Type 1794:** The Signaling Group reported that the far end has detected excessive packet latency or loss. This error places the SIP B-channels into an out of service far-end state.
- k. **Error Type 2561:** The signaling group is registered to a Survivable Remote Server.
  - l. **Error Type 3073:** A TLS connection was established with the far-end but authentication with the far-end's TLS certificate failed. Due to this condition, the signaling group will be placed in far-end bypass state so that no outgoing calls will be allowed,. The trunks in the group will be placed in an out of service far end state (OOSFE). Incoming calls will be accepted, but until the far-end's TLS certificate is remedied, these will not be successful. Once the far-end's certificate is remedied, an incoming call can succeed and the trunk group will be put back in service.
- m. **Error Type 3329:** The near end TLS certificate is bad. The trunks in the group will be placed in a near end out of service state and the signaling group will be placed in bypass. No trunk calls either incoming or outgoing will be allowed until the near end's certificate is corrected. The system is warm started (reset system 1), and the signaling groups go through a busy/release action. If the near end certificate is bad, listen sockets fro the signaling group will not be created, so this alarm is raised at the creation of the listen socket stage (i.e., when initially bringing the signaling group into service).

**Note:**

Near end certificate authentication is the process of validating that the server certificate is OK, i.e., we have the private key and the certificate is trusted. This will only break if a user with root access has changed the certificate private key file.

- n. **Error Type 3585:** IP Signaling Far-end Status Test failed. The far-end is not available. See [IP Signaling Group Far-End Status Test \(#1675\)](#) for more information.

- o. **Error Types 3842 - 3942:** These Error Types report certain error messages received by the SIP Signaling Group for one of its associated D-channels. The aux data field shows for which D-channel the message was received.

The generated error code is represented by the value 3840+x, where “x” is the Cause Value. The Cause Value provides additional data that may be useful when tracking down obscure networking and routing problems.

[Table 230: Descriptions and Recommendations for Error Types 3842-3942](#) provides a description of the error code and the recommended actions to troubleshoot the problem.

**Table 230: Descriptions and Recommendations for Error Types 3842-3942 1 of 10**

| <b>Error Code</b> | <b>Description/Recommendation</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|-------------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3842              | Cause Value 2. A request has been made to use a transit network or common carrier that cot be accessed. The equipment sending this cause event does not recognize the transit network. <ol style="list-style-type: none"> <li>1. From the circuit pack or media module and port number (in the Aux Data field), determine the trunk group against which the error was reported.</li> <li>2. Check every routing pattern containing this trunk group for validity of interexchange carriers requested (IXC field).</li> </ol> |
| <b>1 of 10</b>    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

**Table 230: Descriptions and Recommendations for Error Types 3842-3942 2 of 10**

| <b>Error Code</b> | <b>Description/Recommendation</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
|-------------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3843              | <p>Cause Value 3. No route to destination. Request received to route call through a transit network that is recognized but not allowed to carry the call or not able to serve the destination. The service provider cot route the call to the indicated destination. Communication Manager does not originate Cause Value 3.</p> <p>The repair steps are based on Tier 4 recommendations:</p> <ol style="list-style-type: none"> <li>1. Check the numbers sent for any missing prefixes or service values that were needed to access the network.</li> <li>2. Check the Cause Information Element Location Code.</li> <li>3. Check Communication Manager administration: <ol style="list-style-type: none"> <li>a. Dial plan/Location: The home NPA is administered incorrectly, causing incorrect code conversion.</li> <li>b. IXC: The IXC matching pattern is administered incorrectly or not at all on the dial plan, causing incorrect IXC manipulation.</li> <li>c. AAR/ARS digit conversion: The wrong digit string substitution is being made. The call is being routed into the wrong network and over the wrong route pattern. Further conversion is needed but the dial string is restricted from further conversion.</li> <li>d. AAR/ARS digit analysis: Call type is incorrect for the call being made specifying the wrong type of number and/or number plan information, or it is preventing code conversion from taking place. Call is being routed to the incorrect route pattern where the incorrect digit manipulation and/or code conversion is taking place.</li> <li>e. ARS toll analysis: Toll/no toll classification is incorrect, causing incorrect code conversion at the route pattern.</li> <li>f. Route pattern: Incorrect code conversion due to wrong entries in NPA, prefix mark, and toll list/prefix mark fields. Deleting the wrong number of digits or inserting the wrong digits. Failing to strip IXC or international code digits, stripping a user-dialed IXC code, or IXC forcing the call to the wrong inter-exchange carrier. Number format changed to a format incorrect for the call type. The incorrect service or feature is specified for the call being made on a CBC trunk group preference.</li> </ol> </li> </ol> |
| <b>2 of 10</b>    |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

**Table 230: Descriptions and Recommendations for Error Types 3842-3942 3 of 10**

| Error Code     | Description/Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|----------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3846           | <p>Cause Value 6. The far-end switch has indicated that the B-channel (trunk) is not acceptable for use in the call for which it was requested.</p> <p>This could indicate an administration problem (for example, the local switch and the far-end switch have different B-channels administered), or could reflect the occurrence of a normal race condition (for example, the local switch has requested use of a B-channel that the far-end switch had just reserved for use on another call).</p> <ol style="list-style-type: none"> <li>1. From the circuit pack or media module and port number (in the Aux Data field), determine the trunk group against which the error was reported.</li> <li>2. Enter <code>status trunk</code> for the indicated trunk. Refer to <a href="#">DS1 ISDN Trunk Service States</a> and <a href="#">ISDN-PRI Trunk Service States</a> sections of <a href="#">ISDN-TRK (DS1 ISDN Trunk)</a> for recovery suggestions.</li> </ol> |
| 3858           | <p>Cause Value 18. The switch sent a message to the far-end switch or terminal adapter that did not respond in the time allowed. The remote device/endpoint did not respond with an ALERTING/PROGRESS/CONNECT indication within the time administered in the T303 or T310 timers Q.931 specification. Cause Value 18 indicates high traffic conditions in the serving network or noisy conditions on the span carrying the D-channel messaging. The noise is causing the loss of messages being sent to the remote device. The remote device might also be unable to respond to the incoming SETUP message. This Cause Value has end-to-end significance and should always be passed back through the network to the user.</p>                                                                                                                                                                                                                                           |
| 3878           | <p>Cause Value 38. The far-end switch has indicated that the network is not functioning correctly and that the condition may last a relatively long period of time (for example, immediately re-attempting the call may not be successful). The network is out of order.</p> <ol style="list-style-type: none"> <li>1. From the circuit pack or media module and port number (in the Aux Data field), determine the trunk group against which the error was reported.</li> <li>2. Consult with the network provider to determine the nature and expected duration of the out-of-service condition.</li> <li>3. Consider modifying every routing pattern containing this trunk group to route calls around the network that is out of service.</li> </ol>                                                                                                                                                                                                                 |
| <b>3 of 10</b> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

**Table 230: Descriptions and Recommendations for Error Types 3842-3942 4 of 10**

| Error Code     | Description/Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |
|----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3890           | <p>Cause Value 50. A request to use a network service has been denied. Administration somewhere on the network has indicated that the requested service has not been subscribed to or purchased for this trunk.</p> <p>This could be a local administration problem only, or a mismatch between the local administration and that of the network provider.</p> <ol style="list-style-type: none"> <li>1. From the circuit pack or media module and port number (in the Aux Data field), determine the trunk group against which the error was reported.</li> <li>2. Display the trunk group form: If the trunk group is Call-by-Call (Service Type is "cbc"), check every routing pattern form containing this trunk group to see if the Service/Feature fields contain the correct network services purchased for this trunk. If the trunk group is not Call-by-Call, check that the Service Type field contains the single network service purchased for this trunk.</li> <li>3. If local administration appears correct, consult with the customer and/or the network provider to determine the services that the customer has subscribed to for this trunk group.</li> </ol> |
| 3892           | <p>Cause Value 52. Protocol detail; may offer a clue if customer is having calls denied with an unexpected intercept tone. If the customer is complaining of unexpected intercept tones and no other cause can be found, escalate the problem and provide the next tier with this Error Log information.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |
| 3894           | <p>Cause Value 54. Protocol detail; may offer a clue if customer is having calls denied with an unexpected intercept tone. First, eliminate any transitory state mismatch problems by entering <i>test port location</i> for the trunk port shown in the Aux Data field. <a href="#">Service State Audit Test (#256)</a> is the important test in the sequence. If this passes satisfactorily, yet the customer continues to complain of unexpected intercept tones and no other cause can be found, escalate the problem and provide the next tier with this Error Log information.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |
| 3902           | <p>FRANCE ONLY: Cause Value 62. Service not authorized.</p> <p>Call rejected. This Cause Value has end-to-end significance and should always be passed back through the network to the user.</p> <p>Cause Value 62 (VN4) indicates that the call could not be completed because the user has not subscribed to the service, feature, or supplementary service requested in the SETUP message. If the user is supposed to have access to this service, feature, or supplementary service, complete the required ordering process with the service provider.</p> <p>Cause Value 62 (1TR6) indicates that the remote endpoint does not wish to accept this call, although it could have accepted the call because the equipment is neither busy nor incompatible. The diagnostic information in the Cause information element might contain the user-supplied condition for why the call was rejected.</p>                                                                                                                                                                                                                                                                          |
| <b>4 of 10</b> |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

| <b>Error Code</b> | <b>Description/Recommendation</b>                                                                                                                                                                                                                                                                                                                                                                                                                  |
|-------------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3903              | Cause Value 63. Service or option not available, unspecified. This cause value is used to report a “service or option not available” event only when no other cause in the “service or option not available” class applies. This Cause Value shall either be passed to the user or mapped to Cause Value 41 (temporary failure) when it is received at a CO as part of SS7 call handling. Communication Manager does not originate Cause Value 63. |
| 3905              | Cause Value 65. Protocol detail; may offer a clue if customer is having ISDN calls denied with an unexpected intercept tone. If the customer is complaining of unexpected intercept tones and no other cause can be found, escalate the problem and provide the next tier with this Error Log information.                                                                                                                                         |
| 3906              | Cause Value 66. Protocol detail; may offer a clue if customer is having ISDN calls denied with an unexpected intercept tone. If the customer is complaining of unexpected intercept tones and no other cause can be found, escalate to the problem and provide the next tier with this Error Log information.                                                                                                                                      |
| 3909              | Cause Value 69. A request to use a network service has been made, but the network has rejected the request because the requested service is not implemented. Follow the recommendation for Error Type <a href="#">3890</a> , Cause Value 50.                                                                                                                                                                                                       |

| Error Code     | Description/Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|----------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3910           | <p>Cause Value 70. Only restricted digital bearer capability available. The call could not be completed because the equipment sending this Cause Value only supports the restricted version of the requested bearer capability, and in the SETUP message, bearer capability was unrestricted. Communication Manager does not originate Cause Value 70.</p> <p>The repair steps are based on recommendations from Tier 4 ISDN experience:</p> <ol style="list-style-type: none"> <li>1. Check Communication Manager administration (network generated the Cause Value): <ol style="list-style-type: none"> <li>a. Route pattern: An incorrect ITC and/or BCIE specified. These fields affect how the bearer capability is encoded in the SETUP message.</li> <li>b. The ITC administered on the originating endpoint might be incorrect for this call and/or the speed options in the device itself might be incorrect for calls over these ISDN facilities.</li> <li>c. Incorrect data speed option is set in the BRI device, causing a call from a BRI endpoint tandeming through Communication Manager to create a SETUP message with the wrong bearer capability.</li> <li>d. A call tandeming through Communication Manager ISDN trunk group to ISDN trunk group might have a bearer capability that is not supported by the outgoing ISDN facilities or network.</li> <li>e. A call tandeming through Communication Manager on a non-ISDN trunk group inter-working to an ISDN trunk group might have an incorrect bearer capability assigned on the incoming trunk group. The BC and ITC fields on the incoming trunk group may be set wrong.</li> </ol> </li> </ol> |
| 3919           | <p>Cause Value 79. Service or option not implemented or unspecified. The call could not be completed because the equipment sending this Cause Value has not implemented a service, feature, or supplementary service requested by the user, and none of the other Cause Values in the Service or Option Not Implemented class apply. As an implementation option, this Cause Value might be mapped to Cause Value 41 (temporary failure) when it is received at a CO as part of SS7 call handling. Communication Manager does not originate Cause Value 79.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

| 3942           | <p>Cause Value 102. Recovery on timer expiry. No answer to CALL PROCEEDING. The equipment sending this Cause Value sent or received a Layer 3 Q.931 message. Sending or receiving this message has initiated a Layer 3 timer that has expired. This Cause Value is being generated in conjunction with Q.931 protocol error handling procedures. The ISDN network between the user and the equipment generating the Cause Value might:</p> <ul style="list-style-type: none"> <li>1 Send no cause indication through the network.</li> <li>1 Send a more generic Cause Value through the network.</li> </ul> <p>The repair steps are based on recommendations from Tier 4 ISDN experience:</p> <ol style="list-style-type: none"> <li>1. Check the diagnostic information for the timer number that has expired.</li> <li>2. Check that the protocols at each end of the interface match (for example, both sides are NI-2).</li> </ol> <p style="padding-left: 40px;">If the ends of the interface are running different protocols, they might be running with different values for their Layer 3 timers.</p> <p style="padding-left: 40px;">If the protocols at each end of the interface match, the Communication Manager timer might have expired because:</p> <ol style="list-style-type: none"> <li>a. The far-end never saw the message because the message was corrupted in transmission by noise on the D-channel. Check for any type of T1/E1 facility errors.</li> <li>b. The far-end is experiencing a high traffic condition and did not have the processing time to parse the sent message before the timer expired.</li> <li>c. Even though the message was seen to be generated in an internal Communication Manager trace, the message was never transmitted out onto the D-channel. Perform an external protocol capture on the D-Channel to confirm the transmission of the suspect message.</li> </ol> |

**Table 230: Descriptions and Recommendations for Error Types 3842-3942 9 of 10**

| Error Code       | Description/Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |
|------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3942<br>(cont'd) | <ol style="list-style-type: none"> <li>3. To interpret the receipt of Cause Value 102 from the far-end, look at a trace/ protocol capture of the messaging taking place, and find the last message received from the far-end before Cause Value 102 is received. The timer that expired is most likely the Layer 3 timer associated with that last message. If Communication Manager generated a message in between those two events that should have stopped the timer, the cause might be:               <ol style="list-style-type: none"> <li>a. The far-end never saw the message because the message was corrupted in transmission by noise on the D-Channel. Check for any type of T1/E1 facility errors.</li> <li>b. The far-end is experiencing a high traffic condition and did not have the processing time to parse the sent message before the timer expired.</li> <li>c. Even though the message was seen to be generated in an internal Communication Manager trace, the message was never transmitted out onto the D-Channel. Perform an external protocol capture on the D-Channel to confirm the transmission of the suspect message.</li> </ol> </li> <li>4. If Communication Manager did not respond to the receipt of the last message from the far-end, then Communication Manager internal hardware and software become suspect, and troubleshooting the problem must proceed from that point.</li> <li>5. Communication Manager administration that can contribute to seeing timer expiry errors:               <ol style="list-style-type: none"> <li>a. Trunk group form: Incoming call handling table. If the Per call CPN/BN field is incorrectly populated in comparison to how the CO is programmed to send CPN or BN, it causes Communication Manager to send a FACILITY message to the CO requesting CPN/BN information and the CO will never respond. Communication Manager will log many timer expiry errors against the signaling group (Error Type 1, Aux Data 13).</li> <li>b. DS1 form: Protocol version: If Communication Manager is running custom protocol (protocol version A) and is connected to a Nortel DMS central office running custom protocol, Communication Manager will log timer expiry errors against the signaling group for DISCONNECT problems (Error Type 1, Aux Data 4) during high traffic conditions.</li> </ol> </li> </ol> |
| <b>9 of 10</b>   |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

**Table 230: Descriptions and Recommendations for Error Types 3842-3942 10 of 10**

| <b>Error Code</b> | <b>Description/Recommendation</b>                                                                                                                                                                                                                                                                                                                                                                                                          |
|-------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 3942<br>(cont'd)  | 6. The DMS CO custom protocol implementation uses the ANSI recommended timer values for their Layer 3 timers while Communication Manager uses the ITU recommended timer values. The T305 timer in Communication Manager is 4 seconds while the same timer in the DMS is 30 seconds. This difference causes timer expiry problems in high traffic conditions. Change Communication Manager's protocol version to "c" to line up the timers. |
| <b>10 of 10</b>   |                                                                                                                                                                                                                                                                                                                                                                                                                                            |

---

## Demand test descriptions and error codes

Investigate tests in the order presented. By clearing errors associated with the first test, errors generated from other tests may also be cleared. Click on the link to see the full description of the test, error codes, and recommended actions.

| Order of Investigation                                         | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|----------------------------------------------------------------|---------------------|--------------------|-------------------|
| <a href="#">C-LAN Ethernet Port Status Test (#1386)</a>        | X                   | X                  | ND                |
| <a href="#">MedPro Status Test (#1392)</a>                     | X                   | X                  | ND                |
| <a href="#">Signaling Group Ping Test (#1387)</a>              | X                   | X                  | ND                |
| <a href="#">IP Signaling Group Far-End Status Test (#1675)</a> |                     | X                  | ND                |

1. D = Destructive; ND = Nondestructive

## SN-CONF (Switch Node Configuration)

### S8700-series Fiber-PNC

| MO Name in Log | Alarm Level | Initial Command to Run                       | Full Name of MO           |
|----------------|-------------|----------------------------------------------|---------------------------|
| SN-CONF        | MAJ         | <code>test board location</code>             | Switch Node Configuration |
|                | MIN         | <code>test board location<sup>1</sup></code> |                           |

1. If the error and alarm logs display the switch node carrier location UUC (cabinet and carrier only), run the long test sequence on the active SNC in the carrier, (slot 10 or 12). If the error and alarm logs display a circuit pack location, run the short test sequence on the alarmed SNI.

A switch node carrier contains:

- 1 Up to 16 Switch Node Interface (SNI) TN573 circuit packs in slots 2 through 9 and slots 13 through 20
- 1 One or two Switch Node Clock (SNC) TN572 circuit packs in slots 10 and 12
- 1 An Expansion Interface (EI) TN570 circuit pack, a DS1 Converter (DS1C) TN574 circuit pack, or no circuit pack in slot 1
- 1 An optional DS1 converter circuit pack in slot 21

SN-CONF errors and alarms are generated for two types of failures:

1. Failure of a board in the switch node carrier to insert (be detected by software).
2. A problem was found by running the [Configuration Audit \(#759\)](#). Test 759 is executed for either an SNI or SNC circuit pack during scheduled maintenance or as part of `test board location`.

For SNI circuit packs, test 759 queries the SNI for SNCs in the same switch node carrier, SNI peers, DS1 converters, and EI or SNI neighbors that the SNI can communicate with and compares this data to the administered data.

For SNC circuit packs, test 759 queries the SNC for SNCs and SNIs in the same switch node carrier that the SNC can communicate with and compares this data to the administered data.

Switch node carriers are part of port-network connectivity (PNC). For background information about PNC, refer to the Maintenance Architecture and Hardware Configurations chapters and related MOs.

## Error log entries and recommended actions

Table 231: SN-CONF Error Log Entries

| Error Type | Aux Data | Associated Test              | Alarm Level | On/Off Board | Recommended Action           |
|------------|----------|------------------------------|-------------|--------------|------------------------------|
| 0 (a)      | 0        | Any                          | Any         | Any          | <i>test board location</i>   |
| 5000 (b)   | Any      | Processor Route Audit (#760) | MIN         | OFF          | <i>test board location 1</i> |
| 6000 (c)   | 1        | Configuration Audit (#759)   | MAJ         | OFF          | <i>test board location</i>   |
| 6000 (c)   | 2        | Configuration Audit (#759)   | MAJ         | OFF          | <i>test board location</i>   |
| 6001 (d)   | Any      | Configuration Audit (#759)   | MAJ         | OFF          | <i>test board location</i>   |
| 6002 (e)   | 1        | Configuration Audit (#759)   | MAJ         | OFF          | <i>test board location</i>   |
| 6002 (e)   | 2        | Configuration Audit (#759)   | MAJ         | OFF          | <i>test board location</i>   |
| 6003 (f)   | Any      | Configuration Audit (#759)   | MAJ         | OFF          | <i>test board location</i>   |
| 6004 (g)   | Any      | Configuration Audit (#759)   | MAJ         | OFF          | <i>test board location</i>   |
| 6005 (h)   | Any      | Configuration Audit (#759)   | MAJ         | OFF          | <i>test board location</i>   |
| 6005 (h)   | 1        | Configuration Audit (#759)   | MAJ         | OFF          | <i>test board location</i>   |
| 6005 (h)   | 2        | Configuration Audit (#759)   | MAJ         | OFF          | <i>test board location</i>   |
| 6006 (i)   | Any      | Configuration Audit (#759)   | MIN         | OFF          | <i>test board location</i>   |
| 6007 (j)   | Any      | Configuration Audit (#759)   | MIN         | OFF          | <i>test board location</i>   |

Notes:

- a. **Error Type 0:** run the short test sequence first. If every test passes, run the long test sequence. Refer to each appropriate test's description, and follow its recommended procedures.
- b. **Error Type 5000:** at least one administered circuit pack in this switch node carrier was not inserted, or one or more administered circuit packs in this switch node carrier did not respond to Test #760 with a "board insertion" uplink message.  
 To resolve this error, run the [Processor Route Audit Test \(#760\)](#) using *test board location 1* for an SNC in the same switch node carrier that has this error.

- c. **Error Type 6000:** no neighbor link is administered, but the SNI has one. If the Aux Data is 1, an EI is connected as a neighbor link. If the Aux Data is 2, an SNI is connected as a neighbor link.

To resolve Error Type 6000 with Aux Data 1, refer to FAIL code 133 for [Configuration Audit \(#759\)](#). To resolve Error Type 6000 with Aux Data 2, refer to FAIL code 134 for the [Configuration Audit \(#759\)](#).

- d. **Error Type 6001:** no neighbor link exists between the SNI and its neighbor, but a neighbor link (that is, fiber link) is administered.

To resolve this error, refer to FAIL code 135 for [Configuration Audit \(#759\)](#).

- e. **Error Type 6002:** the physical neighbor type does not match administration. The associated Aux Data value is the location reported by the neighbor SNI that did not match the fiber link administration. If the aux data is 1, the type of neighbor administered is an SNI and the type of neighbor connected is an EI. If the aux data is 2, the type neighbor administered is an EI and the type of neighbor connected is an SNI.

To resolve Error Type 6002 with aux data 1, refer to FAIL code 136 for [Configuration Audit \(#759\)](#). To resolve Error Type 6002 with aux data 2, refer to FAIL code 137 for [Configuration Audit \(#759\)](#).

- f. **Error Type 6003:** the neighbor location does not match administration. To resolve this error, refer to FAIL code 138 for [Configuration Audit \(#759\)](#).

- g. **Error Type 6004:** a peer link does not exist to another equipped SNI. The Aux Data equals the slot number of the SNI to which this SNI or SNC does not have a peer link. To resolve this error, refer to the FAIL code for [Configuration Audit \(#759\)](#) corresponding to the Aux Data on the following table:

| Aux Data (slot no.) | Test 759 FAIL Code |
|---------------------|--------------------|
| 2                   | 102                |
| 3                   | 103                |
| 4                   | 104                |
| 5                   | 105                |
| 6                   | 106                |
| 7                   | 107                |
| 8                   | 108                |
| 9                   | 109                |
| 13                  | 113                |

*1 of 2*

| Aux Data<br>(slot no.) | Test 759<br>FAIL Code |
|------------------------|-----------------------|
| 14                     | 114                   |
| 15                     | 115                   |
| 16                     | 116                   |
| 17                     | 117                   |
| 18                     | 118                   |
| 19                     | 119                   |
| 20                     | 120                   |
| <b>2 of 2</b>          |                       |

h. **Error Type 6005:** a link does not exist to one of the SNCs. If the Aux Data is not 1 or 2, the link from this SNI to the active SNC does not exist. If the Aux Data is 1, the link from this SNC to the active SNC does not exist. If the Aux Data is 2, the link from this SNC to the standby SNC does not exist.

To resolve this error, refer to FAIL code 112 for [Configuration Audit \(#759\)](#).

i. **Error Type 6006:** the SNI is administered to be connected to a DS1C but is not.

To resolve this error, refer to FAIL code 139 for [Configuration Audit \(#759\)](#).

j. **Error Type 6007:** the SNI is connected to a DS1C, but no DS1C is administered.

To resolve this error, refer to FAIL code 140 for [Configuration Audit \(#759\)](#).

---

## Demand test descriptions and error codes

Investigate tests in the order presented. By clearing errors associated with the first test, errors generated from other tests may also be cleared. Click on the link to see the full description of the test, error codes, and recommended actions.

| Order of Investigation                            | Short Test Sequence | Long Test Sequence | Reset Board Sequence | D/ND <sup>1</sup> |
|---------------------------------------------------|---------------------|--------------------|----------------------|-------------------|
| <a href="#">Configuration Audit (#759)</a>        | X                   | X                  |                      | ND                |
| <a href="#">Processor Route Audit Test (#760)</a> |                     | X                  |                      | ND                |

1. D = Destructive, ND = Nondestructive

## SNC-BD (Switch Node Clock Circuit Pack)

### S8700-series Fiber-PNC

| MO Name in Log | Alarm Level | Initial Command to Run           | Full Name of MO  |
|----------------|-------------|----------------------------------|------------------|
| SNC-BD         | MAJ<br>MIN  | <code>test board location</code> | SNC Circuit Pack |

The Switch Node Clock (SNC) TN572 circuit pack is part of the Center Stage Switch (CSS) configuration. It resides in a switch node carrier that alone or with other switch nodes make up a CSS. In a high-reliability system (duplicated server and control network, unduplicated PNC), each SNC is duplicated such that there are two SNCs in each switch node carrier. In a critical-reliability system (duplicated server, control network, and PNC), each switch node is fully duplicated, and there is one SNC in each switch node carrier. SNCs are placed in slots 10 and 12 of the switch node carrier.

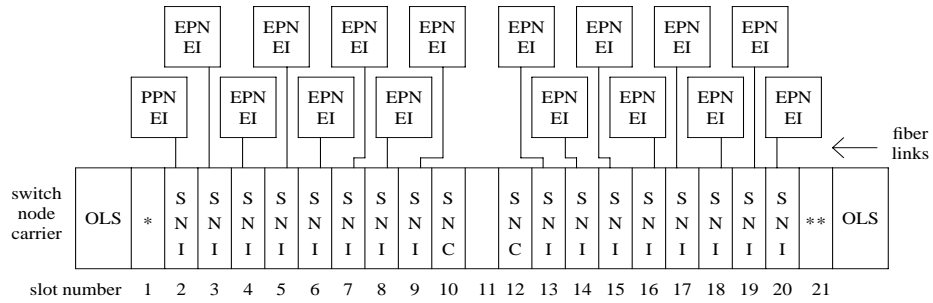

The active SNC communicates with each circuit pack in the switch node carrier over the serial channel bus on the backplane. In addition, the active SNC provides timing to the circuit packs in the switch node carrier via the clock buses. The active SNC uses Timing Priority Number (TPN) links with each Switch Node Interface (SNI) and the other SNC to receive and distribute TPNs. TPNs are used for setting up the correct timing distribution for the switch node carrier. The active SNC receives timing for the switch node carrier from each SNI circuit pack in the carrier and chooses the SNI with the best timing reference for the switch node carrier timing signal the SNC puts out on the clock buses. The timing reference for each SNI is derived from the fiber signal to each SNI. The active SNC chooses the SNI to receive timing from by choosing the SNI with the lowest numbered TPN which means that the SNI is closest to the system timing source. The active SNC also verifies that the SNI reference signal is good before using that SNI as the timing reference for the switch node carrier. The active SNC then supplies this timing over the clock buses on the backplane to every SNI and SNC circuit pack in the carrier. For more information about timing synchronization (including how the SNC fits into the overall synchronization configuration), see [SYNC \(Port Network Synchronization\)](#).

The SNC circuit packs are associated with three MOs:

- 1 The [SNC-BD \(Switch Node Clock Circuit Pack\)](#) MO covers general SNC board errors and errors with the serial communication channel between the active and standby SNCs.
- 1 The [SNC-LINK \(Switch Node Clock Link\)](#) MO covers errors between the active SNC and SNIs over the serial channel (Aux Data is 1). Also, the SNC-LINK MO covers TPN Link errors between the active SNC and SNIs (Aux Data is 2).
- 1 The [SNC-REF \(Switch Node Clock Reference\)](#) MO covers errors the active SNC detects with SNI reference signals.

SNC circuit packs are part of port-network connectivity (PNC). For background information about PNC, refer to the Maintenance Architecture and Hardware Configurations chapters.

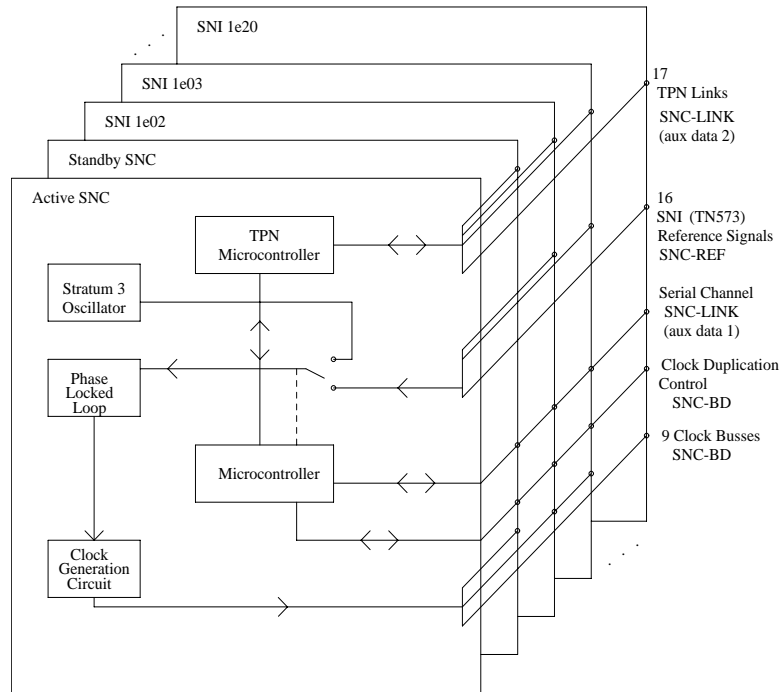

**Figure 67: A Center Stage Switch Configuration**

\* = An EI or a DS1C circuit pack may reside in this slot  
 \*\* = A DS1C circuit pack may reside in this slot

Switch Node Clock (SNC) TN572  
 Switch Node Interface (SNI) TN573  
 Expansion Interface (EI) TN570  
 DS1 Converter (DS1C) TN574  
 Online Switcher (OLS) power supply

**Figure 68: SNC Functions**

---

## SNC LEDs

SNC circuit packs have the standard red, green, and yellow LEDs. The red and green LEDs operate as usual: red means an alarm condition and green indicates maintenance testing in progress. If the yellow LED is lit, this indicates that the SNC is the active circuit pack, supplying timing to the carrier. In a duplex- or high-reliability system (unduplicated PNC), the standby SNC in a carrier is unlit. In a critical-reliability system (duplicated PNC), an SNC in a standby switch node carrier is lit since it is providing timing for the standby carrier.

---

## Clear Firmware-Counters Command

SNC firmware generates error reports independently of demand tests. Therefore, `test board location clear` does not affect the error status reported by firmware. The `clear firmware-counters` command clears every firmware-generated error unconditionally.

Use `clear firmware-counters location` to send a downlink message to the SNC circuit pack, causing it to clear out its firmware error counters and failure database. When the firmware failure database is cleared, the [Failure Audit \(#777\)](#) will pass. If problems still exist, the firmware increments its error counters and the failure audit test begins failing again.

Do not use this command instead of the repair procedures associated with the error log entries. This command may be useful if a problem was fixed but the off-board alarms associated with the problem are still active.

---

## Replacing SNC Circuit Packs

Do not power down a Switch Node carrier to replace a circuit pack. Replacing an SNC on a system with unduplicated SNCs disrupts service.

## Standard-Reliability System (Unduplicated server, PNC, and SNCs)

**This procedure is destructive. Any links through the switch node carrier will go down.**

1. Pull out the SNC circuit pack to be replaced.
2. Insert a new SNC circuit pack.
3. Wait for the SNC to reset. (The red and green LEDs light and then go out. The yellow LED should be on solid.)
4. Use `test alarm long clear category exp-intf`. *Do not busyout the Expansion Interface circuit packs.*
5. Wait 5 minutes for SNI-BD, SNI-PEER, FIBER-LK, and DS1C-BD alarms to clear, or enter `clear firmware-counters`.

## High-Reliability System (Duplicated Server and SNCs, Unduplicated PNC)

This procedure is **nondestructive**.

1. If the SNC circuit pack to be replaced is the active SNC in the switch node carrier (yellow LED is on solid), use `set switch-node-clock` to set the standby SNC to active.
2. When the SNC circuit pack is in standby mode (yellow LED is off), pull out the SNC circuit pack to be replaced.
3. Insert a new SNC circuit pack.
4. Wait for the SNC to reset. (The red and green LEDs light and then go out.) The yellow LED should be off because the SNC circuit pack is in standby mode.

## Critical-Reliability System (Duplicated Server and PNC)

On a system with duplicated PNC, synchronization may be provided over a combination of active and standby components. This condition is indicated by an OFF-BOARD WRN alarm against TDM-CLK with Error Type 2305. Repairs to standby PNC in this state may disrupt service. Otherwise, if the active PNC is functional, replacement of a standby component will not disrupt service.

To replace an SNC circuit pack in a critical-reliability system:

1. Enter `status pnc`.  
Verify that the component to be replaced is on the standby PNC.
2. Enter `busyout pnc`.
3. Enter `busyout board location`.
4. Replace the circuit pack.
5. Enter `release board location`.

### CAUTION:

Do not busyout any Expansion Interface circuit pack after this point.

6. Enter `test alarms long clear` for category `exp-intf`.
7. Wait 5 minutes for SNI-BD, SNI-PEER, FIBER-LK, and DS1C alarms to clear, or enter `clear firmware-counters a-pnc | b-pnc`. Use the letter designation of the PNC that holds the replaced component (the standby PNC).
8. Enter `status pnc`.  
If either PNC's state of health is not "functional", consult [PNC-DUP \(PNC Duplication\)](#).
9. Enter `release pnc`.

## Error log entries and recommended actions

Table 232: SNC-BD Error Log Entries

| Error Type | Aux Data | Associated Test         | Alarm Level | On/Off Board | Recommended Action            |
|------------|----------|-------------------------|-------------|--------------|-------------------------------|
| 0 (a)      | 0        | Any                     | Any         | Any          | <i>test board location</i>    |
| 1 (b)      | Any      | Failure audit (#777)    | MAJ         | ON           | <i>test board location</i>    |
| 18 (c)     | 0        | busyout board location  | WRN         | OFF          | <i>release board location</i> |
| 257 (d)    | Any      | Failure audit (#777)    | MAJ         | OFF          | <i>test board location</i>    |
| 513 (e)    | Any      | Failure audit (#777)    | MIN         | OFF          | <i>test board location</i>    |
| 769 (f)    | Any      | Failure audit (#777)    | MIN         | OFF          | <i>test board location</i>    |
| 1025 (g)   | Any      | Failure audit (#777)    | MAJ         | ON           | <i>test board location</i>    |
| 1281 (h)   | Any      | Failure audit (#777)    | MIN         | OFF          | <i>test board location</i>    |
| 1537 (i)   | Any      | Failure audit (#777)    | MIN         | ON           | <i>test board location</i>    |
| 1793 (j)   | Any      | Failure audit (#777)    | MAJ         | ON           | <i>test board location</i>    |
| 2049 (k)   | Any      | Failure audit (#777)    | MAJ         | ON           | <i>test board location</i>    |
| 6008 (l)   | 0        | SNC Release/Busy (#781) |             |              |                               |

Notes:

- a. **Error Type 0:** Run the short test sequence first. If every test passes, run the long test sequence. Refer to each appropriate test's description, and follow its recommended procedures.
- b. **Error Type 1:** SNC on-board microcontroller error. Replace the SNC circuit pack.
- c. **Error Type 18:** the SNC circuit pack was busied out using *busyout board location*. To resolve this error, use *release board location* to release the SNC circuit pack.
- d. **Error Type 257:** firmware detects failure of the phase-locked loop, inability to lock, or failure of the clock drivers. The problem is off-board.
  1. Enter **display errors**. If SNC-BD Error Type 1793 exists in the error log, follow the repair procedures for SNC-BD Error Type 1793.
  2. Enter **display errors**. If no SNI-BD 1025 errors exist in the error log, replace the active SNC.
  3. Enter **display errors**. If any SNI-BD 1025 errors exist in the error log, follow the repair procedure in [SNI-BD \(SNI Circuit Pack\)](#) for these errors.

- e. **Error Type 513:** the active SNC determines that there is a problem communicating with the standby SNC via the connecting serial channel.

If the switch node carrier is administered with duplicate SNCs:

1. If the standby SNC (the one with its yellow LED off) has this error, escalate the problem. (`status switch-node` also shows the active and standby SNCs.)
2. If the system originally had duplicate SNCs and the standby SNC was removed and never replaced and the active SNC has not been reset after the standby SNC was removed, this error will occur.

If you do not intend to replace the SNC:

- a. Remove the standby SNC from circuit pack administration using `change circuit-pack`.
- b. If the problem persists, replace the active SNC circuit pack. Otherwise, insert an SNC circuit pack.
3. Use `display errors` to check the error log. If SNIs in the switch node carrier also have problems communicating with the active SNC (i.e., error code 257 is logged against SNI-BD), then replace the active SNC.
4. Replace the standby SNC circuit pack.
5. Retry `test board`. Use `display errors` to check the error log. If this error is still in the error log, replace the active SNC.

If the switch node carrier is administered with only one SNC:

1. If step 2 above does not apply, replace the SNC.

- f. **Error Type 769:** the standby SNC determined that there is a problem communicating with the active SNC through the connecting serial channel.

1. If the active SNC (yellow LED is on) has this error, escalate the problem. (The `status switch-node` command also shows the active and standby SNCs.)
2. Use `display errors` to check the error log. If more than one SNI in the switch node carrier has problems communicating with the active SNC (that is, Error Type 257 is logged against SNI-BD), then replace the active SNC.
3. If a single SNI has SNI-BD error 257, replace the SNI circuit pack.
4. Replace the standby SNC circuit pack.
5. Retry `test board`. Use `display errors` to check the error log. If this error is still in the error log, replace the active SNC.

- g. **Error Type 1025:** the firmware detects problems with the various hardware circuit monitors that verify correct operation of the reference links. Replace the SNC circuit pack.

- h. **Error Type 1281:** the firmware detected problems with the interface used to track the status of both SNCs when there are duplicated SNCs in a switch node carrier. Software may have incorrect information for which SNC is active.
- If the switch node carrier has only one SNC, replace the SNC.
- If the switch node carrier has duplicate SNCs:
1. Replace the SNC that does not have its yellow LED lit.
  2. Retry **test board**. Use **display errors** to check the error log. If the error is still in the error log, replace the SNC that has its yellow LED lit.
- i. **Error Type 1537:** loss of signal from the SNC on-board Stratum-3 oscillator detected by the firmware. Replace the SNC circuit pack.
- j. **Error Type 1793:** firmware detects failure of the phase-locked loop, inability to lock, or failure of the clock drivers. The problem is on-board. Replace the SNC circuit pack. If the error persists, follow normal escalation procedures.
- k. **Error Type 2049:** firmware detects problems with the microcontroller used for Timing Priority Number processing. Replace the SNC circuit pack.
- l. **Error Type 6008:** There is a status mismatch between software and firmware. This is a status indication and not a real problem. There is no repair action. Test #781 is not a demand test.

---

## Demand test descriptions and error codes

Investigate tests in the order listed. Click on the link to see the full description of the test, error codes, and recommended actions. Test #983 is not an actual demand test. It reports the results of **clear firmware-counters**. Refer to error codes listed for [Failure Audit \(#777\)](#).

| Order of Investigation                              | Short Test Sequence | Long Test Sequence | Reset Board Sequence | D/ND <sup>1</sup> |

# SNC-LINK (Switch Node Clock Link)

S8700-series Fiber-PNC

| MO Name in Log | Alarm Level | Initial Command to Run     | Full Name of MO |
|----------------|-------------|----------------------------|-----------------|
| SNC-LINK       | MIN         | <i>test board location</i> | SNC Link        |

The SNC-LINK MO reports errors in communications between the active Switch Node Clock and Switch Node Interfaces over the serial channel (Aux Data 1) and the TPN link (Aux Data 2). SNC-LINK errors are described on the following pages. For a complete description of SNCs and SNIs, including circuit pack replacement instructions, see [SNI-BD \(SNI Circuit Pack\)](#) and [SNC-BD \(Switch Node Clock Circuit Pack\)](#).

## Error log entries and recommended actions

| 3329       | 2 (c)    | 18                    | Failure audit (#777) | MIN         | OFF          | test board location |
| 3585       | 1 (b)    | 19                    | Failure audit (#777) | MIN         | OFF          | test board location |
| 3585       | 2 (c)    | 19                    | Failure audit (#777) | MIN         | OFF          | test board location |
| 3841       | 1 (b)    | 20                    | Failure audit (#777) | MIN         | OFF          | test board location |
| 3841       | 2 (c)    | 20                    | Failure audit (#777) | MIN         | OFF          | test board location |
|            |          |                       |                      |             |              | <b>2 of 2</b>       |

1. The location of the SNI with which the SNC cot communicate.

Notes:

- a. **Error Type 0:** run the short test sequence first. If every test passes, run the long test sequence. Refer to each appropriate test's description, and follow its recommended procedures.

- b. This error occurs when the active SNC determines that there is a problem communicating with an SNI circuit pack in the same carrier via the connecting multiprocessor serial channel used for transmitting CSCN messages. The slot location of the SNI with which the SNC cot communicate is given in [SNC-LINK Error Log Entries](#).
1. Use **display errors** to check the error log.
  2. If a SNI-PEER error exists in the error log, follow the repair procedures for [SNI-PEER \(SNI Peer Link\)](#).
  3. If the SNC has SNC-LINK errors with Aux Data of 1 against other SNIs and/or has SNC-BD error 513, replace the SNC circuit pack.
  4. If SNIs in the same carrier have SNI-BD error 257 logged indicating they are having trouble communicating with the SNC, replace the SNC circuit pack.
  5. Use **list configuration carrier** to determine whether an SNI is physically present in the slot pointed to by the SNC-LINK error.
    1. If the **Vintage** field indicates that a circuit pack is present, proceed to step [6](#).
    1. If the **Vintage** field shows **no board**:
 

If an SNI should not be installed in this slot:

      - Remove the SNI from circuit pack administration with **change circuit-pack**.
      - If the error remains, re-administer the SNI circuit pack and then remove it from administration again.
      - If the error still remains, replace the active SNC circuit pack.

If an SNI should be installed in this slot, but is missing, insert an SNI circuit pack.
  6. Replace the SNI that the SNC is complaining about.
  7. Retry the command. If this error is still in the error log:
  8. Replace the SNC circuit pack.
  9. If a standby SNC (the one with its yellow LED off) has this error, escalate the problem. Use **status switch-node** to show the active and standby SNCs.
- c. This error occurs when the active SNC determines that there is a problem communicating with an SNI circuit pack in the same carrier via the TPN communication channel. The slot location of the SNI with which the SNC cot communicate is given in [Table 233: SNC-LINK Error Log Entries](#).
1. Use **display errors** to check the error log. If more than one SNI in the same carrier have SNI-BD errors with Error Type 769, replace the SNC.
  2. Use **display errors** to check the error log. If the SNC has more than one SNC-LINK error with Aux Data of 2, replace the SNC.

3. Verify that the SNI the SNC is complaining about exists in the slot indicated by the error code. If the SNI does not exist:
 

If you do not intend to replace the SNI:

  - a. Use `change circuit-pack` to remove the SNI from circuit pack administration.
  - b. If the error remains, re-administer the SNI circuit pack and then remove it from administration again.
  - c. If the problem persists, replace the active SNC circuit pack.

Otherwise:

  - d. Insert an SNI circuit pack.
4. Replace the SNI circuit pack that the SNC is complaining about.
5. Retry the command. If this error is still in the error log, replace the SNC circuit pack.
6. If a standby SNC (the one with its yellow LED off) has this error, escalate the problem. Use `status switch-node` to show the active and standby SNCs.
7. Retry the command. If this error is still in the error log, escalate the problem.

---

## Demand test descriptions and error codes

Investigate tests in the order presented. By clearing errors associated with the first test, errors generated from other tests may also be cleared. Click on the link to see the full description of the test, error codes, and recommended actions.

Table 234: SNC-REF Error Log Entries 2 of 2

| Error Type | Aux Data | SNI Slot <sup>1</sup> | Associated Test      | Alarm Level | On/Off Board | Recommended Action         |
|------------|----------|-----------------------|----------------------|-------------|--------------|----------------------------|
| 3585 (b)   | Any      | 19                    | Failure audit (#777) | MAJ         | OFF          | <i>test board location</i> |
| 3841 (b)   | Any      | 20                    | Failure audit (#777) | MAJ         | OFF          | <i>test board location</i> |
|            |          |                       |                      |             |              | <b>2 of 2</b>              |

1. The slot location of the SNI with which the SNC cot communicate.

## Notes:

- a. **Error Type 0:** run the short test sequence first. If every test passes, run the long test sequence. Refer to each appropriate test's description, and follow its recommended procedures.
- b. This error occurs when the active or standby SNC detects problems in its timing reference with an SNI circuit pack in the same carrier. The slot location of the SNI with which the SNC cot communicate is given in the previous error table.

If duplicated SNCs exist in the carrier:

1. If the SNCs are duplicated in the carrier, use **display errors** to check the error log. If both SNCs have this error, replace the SNI that the SNCs are complaining about.
2. If the error occurred only on the standby SNC and the active SNC in the carrier does not have this error, use **reset board** to reset the standby SNC. Use **status switch-node** to show the active and standby SNCs. If the error returns after the standby has been reset, replace the standby SNC.
3. Retry the command. If this error is still in the error log, continue with the following steps.
4. If the active SNC has this error, use **set switch-node-clock** to set the standby SNC to active. If the new active SNC has this error, replace the SNI that the SNC is complaining about. Otherwise, replace the SNC that originally had this error.

If only one SNC exists in the carrier:

5. Replace the SNI that the SNC is complaining about.
6. Retry the command. If this error is still in the error log, continue with the following step.
7. Replace the SNC.

---

## Demand test descriptions and error codes

Investigate tests in the order presented. By clearing errors associated with the first test, errors generated from other tests may also be cleared. Click on the link to see the full description of the test, error codes, and recommended actions.

| Order of Investigation                              | Short Test Sequence | Long Test Sequence | Reset Board Sequence | D/ND <sup>1</sup> |
|-----------------------------------------------------|---------------------|--------------------|----------------------|-------------------|
| <a href="#">Configuration Audit (#759)</a>          | X                   | X                  |                      | ND                |
| <a href="#">Failure Audit (#777)</a>                | X                   | X                  |                      | ND                |

## SNI-BD (SNI Circuit Pack)

### S8700-series Fiber-PNC

| MO Name in Log | Alarm Level       | Initial Command to Run           | Full Name of MO  |
|----------------|-------------------|----------------------------------|------------------|
| SNI-BD         | MAJ<br>MIN<br>WRN | <code>test board location</code> | SNI Circuit Pack |

The TN573 Switch Node Interface (SNI) circuit pack is part of the Center Stage Switch (CSS) configuration. It resides in a switch node carrier that alone or with other switch nodes make up a CSS. SNIs connect to other SNIs or Expansion Interface (EI) circuit packs via fiber links. SNI-to-EI fiber links are used to connect port networks to a switch node carrier and SNI-to-SNI fiber links are used as inter-switch node fibers. In critical-reliability systems, the fiber link connections are duplicated as part of port-network connectivity (PNC) duplication. In standard- and high-reliability systems, the PNC is not duplicated.

There may be up to 16 SNIs in a switch node carrier. They are located in slots 2 through 9 and slots 13 through 20. Slot 11 in a switch node carrier is not used. One or two TN572 boards (SNCs) must reside in switch node carrier positions 10 and 12. The SNIs connect to other SNIs in the same carrier via the backplane; these connections within the same carrier are referred to as peer-links. Each SNI also connects via an optical fiber or metallic connection to another SNI in another carrier or to an EI in a port network (PN). These connections are referred to as fiber links.

The Switch Node Clock (SNC) provides timing for the SNIs in the entire carrier. When two SNCs reside in the same switch node carrier, one is in active mode and one is in standby mode. The yellow LED on the active SNC will be on solid. The yellow LED on the standby SNC will be off. See [SYNC \(Port Network Synchronization\)](#) for an explanation of how SNIs are involved in timing synchronization.

[Figure 69: CSS Configuration with Unduplicated PNC and 1 Switch Node Carrier](#) shows an unduplicated CSS with one switch node. A single switch node can accommodate up to 16 port networks. A system with two switch nodes can accommodate up to 22 port networks.

[Figure 70: CSS Configuration with Duplicated PNC and 4 Switch Node Carriers](#) shows a two-switch node CSS with duplicated PNC (four switch node carriers). In this configuration, each PNC (A and B) contains two switch nodes. The cabinet numbers for the switch node carriers are typical cabinet numbers. The PNs on the top half of the figure (PNC A) are the same as the PNs on the bottom half of the figure (PNC B).

**Figure 69: CSS Configuration with Unduplicated PNC and 1 Switch Node Carrier**

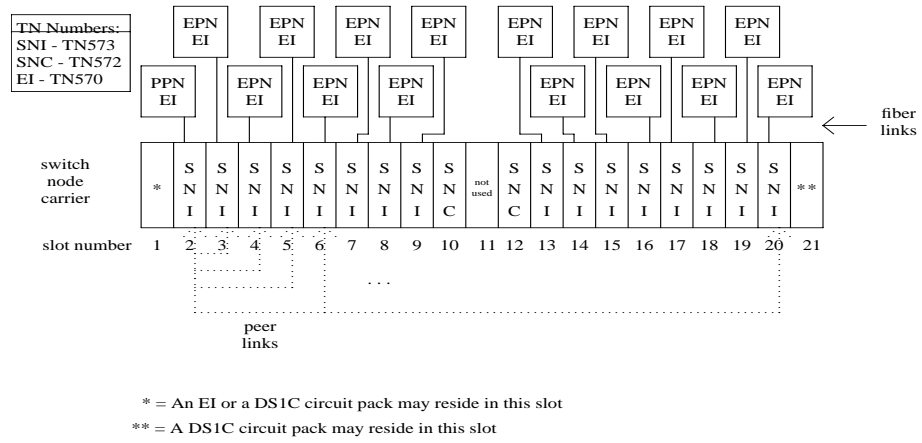

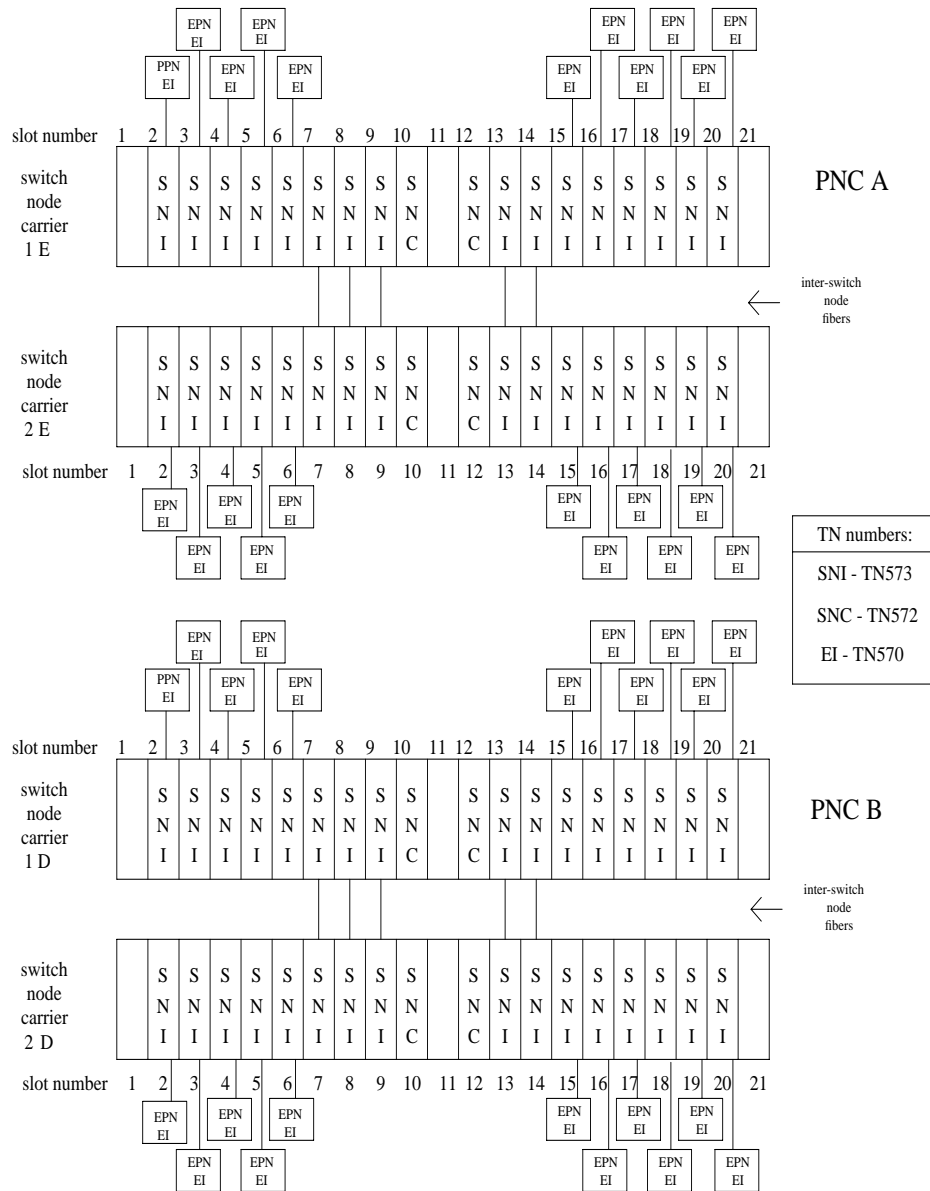

Figure 70: CSS Configuration with Duplicated PNC and 4 Switch Node Carriers

---

## Remote PNs

A DS1 converter complex can provide connectivity to a remotely located port network. The DS1 converter complex consists of two TN574 DS1 converter (DS1C) circuit packs connected by 1 to 4 DS1 facilities. The DS1C complex is administered as a fiber link.

---

**Figure 71: Fiber Link over a DS1 Converter Complex**

---

## SNI LEDs

The SNI circuit pack has red, green, and yellow LEDs. The red and green LEDs have the usual meaning, with red signifying an on-board alarm, and green signifying maintenance testing in progress. The red and green LEDs will come on and then turn off when the circuit pack is reset.

**Note:**

If the red LED is on without any alarms active against the circuit pack, replace the SNI circuit pack. This indicates that SNI firmware has detected a fault and is unable to notify software.

The yellow LED indicates status information:

**Table 235: SNI Yellow LED states**

| Condition                          | LED on     | LED off    |
|------------------------------------|------------|------------|
| Fiber out of Frame                 | 0.1 second | 0.1 second |
| In frame, No Neighbor <sup>1</sup> | 0.5 second | 0.5 second |
| SNI active                         | solid on   | never off  |
| SNI standby                        | never on   | solid off  |

1. The fiber is in frame but a communication problem exists to the neighbor.

---

## SNI Administration and SNI Board Insertion

The circuit packs in the switch node carrier will not function properly unless administration is performed first. For example, without fiber link administration, phone calls cannot be made through the CSS, CSS circuit packs will not be inserted, and maintenance software cannot test the CSS circuit packs.

For an unduplicated PNC configuration, perform the following administration, in this order, before inserting SNIs:

1. Cabinet Administration: administer the switch node carriers into the proper cabinets. When the screen is submitted, switch node numbers are assigned to the carriers. Use `list cabinet` to see the switch node numbers for the carriers.
2. Circuit Pack Administration: Every board in the switch node carriers must be administered.
3. Fiber-Link Administration: Use `add fiber-link` to administer the fibers between the TN570s and the TN573 (or TN573 to TN573), and to add a DS1C converter complex to a fiber link.

For a duplicated PNC configuration, perform the following administration, in this order, before inserting SNIs:

1. Obtain a License File to activate PNC duplication.
2. Cabinet Administration: Administer the switch node carriers and duplicate switch node carriers into the proper cabinets. When this screen is submitted, switch node numbers are assigned to the carriers. Use `list cabinet` to see the switch node numbers for the carriers.
3. Circuit Pack Administration: Every board in the switch node carriers must be administered.
4. Fiber-Link Administration: Use `add fiber-link` to administer the fibers between the TN570s and the TN573 (or TN573 to TN573), and to add a DS1C converter complex to a fiber link. If the system is being changed from an unduplicated to a duplicated PNC configuration, use `change fiber-link` to administer the b-pnc fiber-link endpoints on the existing fiber links.
5. Use `change system-parameters duplication` to administer PNC duplication.

---

## Clear Firmware-Counters Command

SNI firmware generates error reports autonomously. This takes place independently of demand tests. Therefore, `test board location` clear does not affect the error status reported by firmware. The `clear firmware-counters` command clears every firmware-generated error unconditionally.

The `clear firmware-counters location` command sends a downlink message to the SNI circuit packs, causing them to clear out their firmware error counters and failure databases. Once the firmware failure database is cleared, the failure audit test (#777) will pass. If problems still exist, the firmware will increment its error counters and the failure audit test will begin failing again.

Do not use this command instead of the repair procedures associated with the error log entries. This command may be useful if a problem was fixed and off-board alarms associated with the problem are still active.

---

## Replacing SNI Circuit Pack—Unduplicated PNC

Do not power down a Switch Node carrier to replace a circuit pack.

Replacing a Switch Node Interface circuit pack on an unduplicated PNC disrupts service. This service effect can cause an outage of a single PN.

To replace a Switch Node Interface circuit pack in an unduplicated PNC:

1. Enter `busyout board location`.
2. Replace the circuit pack.
3. Wait for the circuit pack to reset.

Red and green LEDs will light and then go out.

4. Enter `release board location`.

 **CAUTION:**

Do not busyout any Expansion Interface circuit pack after this point.

5. Enter `test alarms long clear` for category `exp-intf`.
6. Wait 5 minutes for SNI-BD, FIBER-LK, and DS1C-BD alarms to clear, or enter `clear firmware-counters a-pnc`.

## Replacing an SNI Circuit Pack— Duplicated PNC

On a system with duplicated PNC synchronization may be provided over a combination of active and standby components. This condition is indicated by an OFF-BOARD WRN alarm against TDM-CLK with Error Type 2305. Repairs to standby PNC in this state may disrupt service. If the active PNC is functional, replacement of a standby component does not disrupt service.

To replace a Switch Node Interface circuit pack in an duplicated PNC:

1. Enter `status pnc`.  
Verify that the component to be replaced is on the standby PNC.
2. Enter `busyout pnc`.
3. Enter `busyout board location`.
4. Replace the circuit pack.
5. Enter `release board location`.

### CAUTION:

Do not busyout any Expansion Interface circuit pack after this point.

6. Enter `test alarms long clear` for category `exp-intf`.
7. Wait 5 minutes for SNI-BD, SNI-PEER, FIBER-LK, and DS1C alarms to clear, or enter `clear firmware-counters sp 0 a-pnc | b-pnc`.  
Use the letter designation of the pnc which holds the replaced component (the standby pnc).
8. Enter `status pnc`.  
If either PNC's state of health is not "functional", consult [PNC-DUP \(PNC Duplication\)](#).
9. Enter `release pnc`.

## Switch Node Interface Manual Loopback Procedure

This procedure is **destructive**.

Use this procedure when an SNI circuit pack cannot be tested by software. This can occur when communication between the switch node carrier and the server is down. Before using this procedure, use `test board location` to run the [Configuration Audit \(#759\)](#) on SNI circuit packs where possible. Also, use `test board location long` to run the [Processor Route Audit Test \(#760\)](#) for the active SNC in the switch node carrier. If the active SNC is not inserted, use `test hardware-group pnc P`, where *P* is `a-pnc` or `b-pnc` to run Test #760.

Before using this procedure, determine if more than one SNI is unable to communicate with software. Verify SNI and SNC circuit pack insertion using the `list configuration carrier location` where *location* is the cabinet and carrier location of a switch node carrier. Check for inserted SNIs and SNCs in every administered switch node carrier.

If every SNI and SNC is not inserted, then “NO BOARD” is displayed for each board in the entire PNC (either the a-pnc or the b-pnc). The link between the IPSI connected PN’s EI (on the PNC where SNI and SNC circuit packs were not inserted) and the connected SNI does not function properly. If this applies:

1. Run `test board location` on the IPSI connected PN’s EI, and fix any problems.
2. Perform the [Expansion Interface Manual Loopback Procedure](#) for the IPSI connected PN’s EI.
3. Perform the [Switch Node Interface Manual Loopback Procedure](#) for the SNI connected to the IPSI connected PN’s EI.
4. Replace the active SNC.

If the system has a 2-level switch node carrier configuration (i.e., SNI-to-SNI fiber links exist) and the SNIs and SNCs in the second switch node carrier only (the switch node carrier that has no SNI connected to the IPSI connected PN’s EI) are not inserted and at least two SNI-to-SNI fiber links exist:

1. Run `test board location long` on the SNIs in the first switch node carrier that are connected to SNIs in the second switch node carrier and fix any problems.
2. Replace the active SNC.
3. Perform the [Switch Node Interface Manual Loopback Procedure](#) for the SNIs in the second switch node carrier that are connected to SNIs in the first switch node carrier.

If software is unable to communicate with a PN’s EI but can communicate with the connected SNI:

1. Run `test board location long` on the connected SNI and fix any problems.
2. Perform the [Expansion Interface Manual Loopback Procedure](#) for the PN EI.

If the connection to the SNI circuit pack is fiber, a short length of optical fiber is required for this procedure. If a metallic cable is used in the connection, remove the metallic connector from the back of the carrier, and install a lightwave transceiver in its place. The short length of optical fiber can then be used.

If this procedure is run on both endpoints on a fiber link (Expansion Interface circuit packs or Switch Node Interface circuit packs), and both check out fine, then the failure is most likely in the connection (fiber or metallic) itself if neither endpoint circuit pack is busied out, but the link remains inactive.

1. Use `busyout board location` to busyout the circuit pack (Expansion Interface or SNI).
2. Disconnect the transmit and receive fiber pair from the lightwave transceiver on the back of the circuit pack (Expansion Interface or Switch Node Interface) slot.

**Note:**

Note which is the transmit fiber and which is the receive fiber for proper re-connection at the end of this procedure. The fiber connected to the transmit side of the lightwave transceiver on one circuit pack should be connected to the receive side of the lightwave transceiver on the circuit pack on the opposite end of the fiber.

3. Using a spare fiber jumper cable, interconnect the transmit and receive jacks of the lightwave transceiver as shown in [Figure 72: Interconnection of Lightwave Transceiver Transmit/Receive Jacks](#).

**Note:**

Make sure that the total length of the fiber jumper cable does not exceed the maximum length recommended for the fiber link connections between cabinets. Test the Expansion Interface or SNI circuit pack within connectivity guidelines so that test results are not influenced due to improper cable length.

4. Go to the front of the cabinet and inspect the yellow LED.
  1. If the yellow LED flashes on at a rate of once per second, the Expansion Interface or Switch Node Interface circuit pack or transceiver should be replaced.
  1. If the yellow LED flashes on at a rate of five times per second, the circuit pack (Expansion Interface or Switch Node Interface) or the lightwave transceiver may need replacement. This may also be due to a faulty system clock on the network containing the Expansion Interface circuit pack or in the switch node carrier containing the SNI.
  1. If the yellow LED was blinking before starting this procedure and the yellow LED is not blinking now, this circuit pack (Expansion Interface or Switch Node Interface) and the lightwave transceiver are functioning properly.
5. Replace faulty component(s) and reconnect the original fiber. Be sure to reconnect the fibers properly as noted in Step 2.
6. Use **release board location** to release the Expansion Interface circuit pack or Switch Node Interface circuit pack.

**Figure 72: Interconnection of Lightwave Transceiver Transmit/Receive Jacks**

## Error log entries and recommended actions

**Table 236: SNI-BD Error Log Entries 1 of 2**

| Error Type | Aux Data | Associated Test               | Alarm Level       | On/Off Board | Recommended Action            |
|------------|----------|-------------------------------|-------------------|--------------|-------------------------------|
| 0 (a)      | 0        | Any                           | Any               | Any          | <i>test board location</i>    |
| 1 (b)      | Any      | Failure audit (#777) (c)      | MAJ<br>MIN<br>WRN | ON           | <i>test board location</i>    |

| 2817 (n)   | Any      | Failure audit (#777) (c)     | MAJ<br>MIN<br>WRN | ON           | <i>test board location</i> |
|            |          |                              |                   |              | <b>2 of 2</b>              |

## Notes:

- a. **Error Type 0:** run the short test sequence first. If every test passes, run the long test sequence. Refer to each test's description, and follow its procedures.
- b. **Error Type 1:** the SNI may have trouble communicating with every other SNI and SNC circuit pack in the switch node carrier.
  1. Replace the SNI circuit pack.

- c. **Failure audit (#777):** The first time you see an SNI-BD error in the error log, run `test board location`. If the failure audit test (#777) fails, enter `display errors` for this SNI circuit pack and continue with the repair procedures for [SNI-BD \(SNI Circuit Pack\)](#) errors.
- d. **Error Type 18:** the SNI circuit pack was busied out using `busyout board location`. To resolve this error, use `release board location` to release the SNI circuit pack.
- e. **Error Type 125:** the SNI circuit pack is incompatible with the TN1654 DS1 Converter board. A TN573B or higher suffix SNI board must be used when connecting to a TN1654 DS1 Converter board.
  - 1. Replace the SNI circuit pack with a newer suffix.
- f. **Error Type 257:** the SNI cot communicate with the active SNC.
  - 1. Use `display errors` to check the error log for other SNI circuit packs with the 257 SNI-BD error. If other SNI circuit packs in the same switch node carrier have error 257, replace the active SNC.
  - 2. Replace this SNI.
  - 3. Replace the active SNC in the same switch node carrier.
  - 4. Enter `display errors`. If this error is still in the error log, follow normal escalation procedures.
- g. **Error Type 513:** the SNI cot communicate with the DS1-C.
  - 1. Perform the [Fiber link fault isolation](#) procedure in *Maintenance Procedures (03-300432)*.
- h. **Error Type 769:** failure communicating synchronization control data with the active SNC.
  - 1. Look at every SNI-BD error in the log using `display errors` and `display alarms` to determine whether to follow [Procedure 1](#) or [Procedure 2](#).

Use the table below that lists pairs of adjacent SNIs:

| Adjacent SNI Slot Numbers | Adjacent SNI Slot Numbers |
|---------------------------|---------------------------|
| 2 & 3                     | 13 & 14                   |
| 4 & 5                     | 15 & 16                   |
| 6 & 7                     | 17 & 18                   |
| 8 & 9                     | 19 & 20                   |

Use [Procedure 2](#) if either of the following two conditions is present:

- 1 At least one pair of adjacent SNIs in this carrier has Error Type 769 with an off-board alarm logged against both SNIs in the pair.
- 1 The active SNC in this carrier has Error Type 257.

If neither of the above is true, follow [Procedure 1](#).

**Procedure 1**

Suspect TPN link or clock generation out-of-lock problem:

1. Enter `display alarms` and `display errors` and follow the procedures for any on-board SNI-BD error and alarm entries.
2. If more than one SNI circuit pack in the same switch node carrier has SNI-BD error 769 with an off board alarm, replace the active SNC in the same carrier.
3. Replace this SNI.
4. Replace the active SNC in the same carrier.

**Procedure 2**

Suspect clock generation out-of-lock problem:

5. If only one SNC exists in this switch node carrier, replace the SNC.
  6. If two SNCs exist in this switch node carrier, set the standby SNC to active by running `set switch-node-clock location` with the standby SNC's *location*.
    1. If the problem goes away, replace the SNC that was previously active. Then use `set switch-node-clock location` to set the SNC that was just replaced to active. If the problem returns, assume that the SNC that was just replaced is not at fault and go to Step 7.
    1. If the problem persists, switch back to the previously active SNC using `set switch-node-clock` and go to Step 7.
  7. Replace the left-most SNI from the pair of adjacent SNIs.
  8. Replace the right-most SNI from the pair of adjacent SNIs.
  9. If none of the above steps cleared this error, this could be a switch node carrier backplane problem.
- i. **Error Type 1025:** a failure communicating synchronization control data over the fiber link.

If the error is logged as an ON-BOARD error:

1. Replace the SNI circuit pack.

If the error is logged as an OFF-BOARD error:

1. Enter `display errors` and follow the repair procedures for FIBER-LK errors.
2. Replace the SNI with this error.
3. Replace the fiber link's other endpoint if no DS1C complex is administered on the fiber link. Use `list fiber-link` to determine if a DS1C complex is administered. If so, replace the circuit packs in this order:
  - a. Replace the DS1C circuit pack connected to this SNI.
  - b. Replace the other DS1C circuit pack.
  - c. Replace the fiber link's other endpoint.

- j. **Error Type 1281:** processor complex failure. Replace the SNI circuit pack.
- k. **Error Type 1537:** excessive slips have occurred.  
 Follow the steps for diagnosing synchronization problems when slips have occurred in the SYNC section.
- l. **Error Type 1793:** SNI missed sanity. Escalate the problem.
- m. **Error Type 2561:** the SNI cot communicate with its neighbor. The SNI is at fault. Replace the SNI circuit pack.
- n. **Error Type 2817:** the SNI cot communicate with one of its peers. The SNI is at fault. Replace the SNI circuit pack.

---

## Demand test descriptions and error codes

Investigate tests in the order presented. By clearing errors associated with the first test, errors generated from other tests may also be cleared. Click on the link to see the full description of the test, error codes, and recommended actions.

| Order of Investigation                                                                                 | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|--------------------------------------------------------------------------------------------------------|---------------------|--------------------|-------------------|
| <a href="#">Configuration Audit (#759)</a>                                                             | X                   | X                  | ND                |

| <a href="#">SNI Destructive Facility Off-Board Test (#756)</a>                                         |                     | X                  | D                 |
| <a href="#">SNI Sanity Timer Test (#964)</a>                                                           | X                   | X                  | ND                |
| The following test is not part of a demand test sequence. It is executed with <code>reset board</code> |                     |                    |                   |
| <a href="#">Switch Node Interface Reset Test (#761)</a>                                                |                     |                    | D                 |

1. D = Destructive, ND = Nondestructive

### Note:

Test #982 is not an actual demand maintenance test. This test number displays the results of `clear firmware-counters`. Refer to error codes listed for [Failure Audit \(#777\)](#)

## SNI-PEER (SNI Peer Link)

S8700-series Fiber-PNC only

| MO Name in Log | Alarm Level       | Initial Command to Run     | Full Name of MO |
|----------------|-------------------|----------------------------|-----------------|
| SNI-PEER       | MAJ<br>MIN<br>WRN | <i>test board location</i> | SNI Peer Link   |

SNI Peers are Switch Node Interfaces residing on the same Switch Node Carrier. SNI-PEER maintenance tests the links between SNI Peers. For a full description of SNIs, including circuit pack replacement, see [SNI-BD \(SNI Circuit Pack\)](#).

---

## Error log entries and recommended actions

Table 237: SNI-PEER Error Log Entries 1 of 2

| Error Type     | Aux Data | SNI Slot <sup>1</sup> | Associated Test      | Alarm Level | On/Off Board | Recommended Action         |
|----------------|----------|-----------------------|----------------------|-------------|--------------|----------------------------|
| 0 <sup>2</sup> | 0        |                       | Any                  | Any         | Any          | <i>test board location</i> |
| 1              | Any      | 2                     | Failure audit (#777) | Any         | OFF          | <i>test board location</i> |
| 257            | Any      | 3                     | Failure audit (#777) | Any         | OFF          | <i>test board location</i> |
| 513            | Any      | 4                     | Failure audit (#777) | Any         | OFF          | <i>test board location</i> |
| 769            | Any      | 5                     | Failure audit (#777) | Any         | OFF          | <i>test board location</i> |
| 1025           | Any      | 6                     | Failure audit (#777) | Any         | OFF          | <i>test board location</i> |
| 1281           | Any      | 7                     | Failure audit (#777) | Any         | OFF          | <i>test board location</i> |
| 1537           | Any      | 8                     | Failure audit (#777) | Any         | OFF          | <i>test board location</i> |
| 1793           | Any      | 9                     | Failure audit (#777) | Any         | OFF          | <i>test board location</i> |
| 2049           | Any      | 13                    | Failure audit (#777) | Any         | OFF          | <i>test board location</i> |
| 2305           | Any      | 14                    | Failure audit (#777) | Any         | OFF          | <i>test board location</i> |
| 2561           | Any      | 15                    | Failure audit (#777) | Any         | OFF          | <i>test board location</i> |
| 2817           | Any      | 16                    | Failure audit (#777) | Any         | OFF          | <i>test board location</i> |
|                |          |                       |                      |             |              | <b>1 of 2</b>              |

**Table 237: SNI-PEER Error Log Entries 2 of 2**

| Error Type | Aux Data | SNI Slot <sup>1</sup> | Associated Test      | Alarm Level | On/Off Board | Recommended Action         |
|------------|----------|-----------------------|----------------------|-------------|--------------|----------------------------|
| 3073       | Any      | 17                    | Failure audit (#777) | Any         | OFF          | <b>test board location</b> |
| 3329       | Any      | 18                    | Failure audit (#777) | Any         | OFF          | <b>test board location</b> |
| 3585       | Any      | 19                    | Failure audit (#777) | Any         | OFF          | <b>test board location</b> |
| 3841       | Any      | 20                    | Failure audit (#777) | Any         | OFF          | <b>test board location</b> |
|            |          |                       |                      |             |              | <b>2 of 2</b>              |

1. Run the short test sequence first. If every test passes, run the long test sequence. Refer to each appropriate test's description, and follow its recommended procedures.
2. The slot location of the SNI at the other end of the peer link indicted by the SNI reporting the error.

For every error in [Table 237: SNI-PEER Error Log Entries](#), the SNI circuit pack reporting the error has a problem with the control path, circuit path, or packet path to the SNI peer in the slot indicated on the error table.

1. Run the [Failure Audit \(#777\)](#) to confirm if the error still exists.
2. If the SNI reports an SNI-PEER error against a slot that does not contain an SNI, either change circuit pack administration using **change circuit-pack** to un-administer the SNI, or insert an SNI into the indicated slot. Use **list configuration carrier** to determine if an SNI circuit pack is inserted. Otherwise, use **display errors** and look at every SNI-PEER error in the log. If either of the following two conditions are present, follow [Procedure 2](#) below:
  - 1 Do many SNIs have SNI-PEER errors pointing to the same 2 adjacent SNIs?
  - 1 Do 2 adjacent SNIs have SNI-PEER errors pointing to many other SNIs?
3. If neither condition is present, follow [Procedure 1](#) below. When using either procedure, see [SNI-BD \(SNI Circuit Pack\)](#) or [SNC-BD \(Switch Node Clock Circuit Pack\)](#) for circuit pack replacement instructions.

| Slot Numbers of Adjacent SNIs | Point to this SNI Pair |
|-------------------------------|------------------------|
| 2, 3                          | 1, 257                 |
| 4, 5                          | 513, 769               |
| 6, 7                          | 1025, 1281             |
| 8, 9                          | 1537, 1793             |
| 13, 14                        | 2049, 2305             |
| 15, 16                        | 2561, 2817             |

| Slot Numbers of Adjacent SNIs | Point to this SNI Pair |
|-------------------------------|------------------------|
| 17, 18                        | 3073, 3329             |
| 19, 20                        | 3585, 3841             |

## Procedure 1

Perform the following steps until the problem is resolved:

1. Perform the [Fiber link fault isolation](#) procedure in *Maintenance Procedures (03-300432)*.
2. Replace the SNI pointed to by the SNI-PEER Error Type. See the SNI Slot column in [Table 237: SNI-PEER Error Log Entries](#).
3. Replace the SNI reporting the SNI-PEER error.
4. Replace the active SNC.

## Procedure 2

If either of the two patterns described before are present, then the clock signal between active SNC and 2 Adjacent SNIs is suspect. Proceed through the following steps until the problem is resolved:

1. If only one SNC exists in this switch node carrier, replace the SNC. If two SNCs exist in this switch node carrier, perform the following steps:
  - a. Set the standby SNC to active by executing `set switch-node-clock location` with the standby SNC's location.
  - b. If the problem persists, switch back to the previously active SNC using `set switch-node-clock` and go to Step [2](#) below.
  - c. If the problem went away, replace the SNC that was previously active. Then set the newly replaced SNC to active. If the problem returns, assume that the SNC that was just replaced was not at fault and go to Step [2](#) below.
2. Replace the left-most SNI from the pair of adjacent SNIs.
3. Replace the right-most SNI from the pair of adjacent SNIs.
4. This could indicate a problem with the switch-node-carrier backplane.

## Demand test descriptions and error codes

Investigate tests in the order presented. By clearing errors associated with the first test, errors generated from other tests may also be cleared. Click on the link to see the full description of the test, error codes, and recommended actions.

| Order of Investigation                                                                           | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|--------------------------------------------------------------------------------------------------|---------------------|--------------------|-------------------|
| <a href="#">Configuration Audit (#759)</a>                                                       | X                   | X                  | ND                |
| <a href="#">Failure Audit (#777)</a>                                                             | X                   | X                  | ND                |
| <a href="#">SNI Fiber Out of Frame Query Test (#989)</a>                                         | X                   | X                  | ND                |
| <a href="#">Packet Neighbor Link Test (#767)</a>                                                 | X                   | X                  | ND                |
| <a href="#">SNI Circuit Path Test (#755)</a>                                                     | X                   | X                  | ND                |
| <a href="#">SNI Destructive Facility On-board Test (#757)</a>                                    |                     | X                  | D                 |
| <a href="#">SNI Destructive Facility Off-Board Test (#756)</a>                                   |                     | X                  | D                 |
| The following test is not part of a demand test sequence. It is executed with <b>reset board</b> |                     |                    |                   |
| <a href="#">Switch Node Interface Reset Test (#761)</a>                                          |                     |                    | D                 |

1. D = Destructive, ND = Nondestructive

## SP-REG-M (Survivable Processor-Main)

| MO Name in Log | Alarm Level | Initial Command to Run | Full Name of MO           |
|----------------|-------------|------------------------|---------------------------|
| SP-REG-M       | MAJ<br>MIN  | None                   | Survivable Processor-Main |

The Survivable Processor object monitors keep-alive message between the main server and the survivable processor, which can be either:

- 1 Survivable Remote Server
- 1 Survivable Core Server

The server exchanges keep-alive messages with each of the survivable processors. If the server does not receive a predetermined number of those messages, both the server and the survivable processor alarm.

If a Survivable Remote Server does not register with a Survivable Core Server, it registers with either the main server or another Survivable Core Server and alarms are not raised.

Possible causes for SP-REG-M alarms include:

- 1 The network is down.
- 1 The server or survivable processor administration is incorrect.

---

## Error log entries and recommended actions

**Table 238: SP-REG-M Error Log Entries**

| Error Type                | Aux Data | Associated Test | Alarm Level | On/Off Board | Recommended Action              |
|---------------------------|----------|-----------------|-------------|--------------|---------------------------------|
| 1 ( <a href="#">a</a> )   | 0-63     |                 | MIN         | OFF          | <code>status ess-cluster</code> |
| 769 ( <a href="#">b</a> ) | 0        |                 | MAJ         | OFF          |                                 |

Notes:

- a. **Error Type 1:** no keep-alive signal from the Survivable Core Server. The Aux Data value displays the number of unregistered and alarmed Survivable Core Server clusters (0 - 63). Possible causes include:
- 1 The main server is down.
  - 1 The network is down.
  - 1 The server or survivable processor administration is incorrect.
  - 1. Use the `status ess-cluster` command to determine which survivable processor is not registered.
  - 2. Determine the network outage or administration problem for this processor.
- b. **Error Type 769:** invalid or wrong NIC address. Unable to access the IP address of the native NIC. Use the Maintenance Web Page to verify/configure the NIC address (**Server Configuration -> Configure Server -> Configure Individual Services -> Configure Interfaces**).

## SP-REG-S (Survivable Processor)

| MO Name in Log | Alarm Level | Initial Command to Run | Full Name of MO      |
|----------------|-------------|------------------------|----------------------|
| SP-REG-S       | MAJ<br>MIN  | None                   | Survivable Processor |

The Survivable Processor object monitors keep-alive message between the main server and the survivable processor, which can be either:

- 1 Survivable Remote Server
- 1 Survivable Core Server

The server exchanges keep-alive messages with each of the survivable processors. If the server does not receive a predetermined number of those messages, both the server and the survivable processor alarm.

Possible causes for SP-REG-S alarms include:

- 1 The network is down.
- 1 The server or survivable processor administration is incorrect.

---

## Error log entries and recommended actions

**Table 239: SP-REG-S Error Log Entries**

| Error Type              | Aux Data | Associated Test | Alarm Level | On/Off Board | Recommended Action |
|-------------------------|----------|-----------------|-------------|--------------|--------------------|
| 513 <a href="#">(a)</a> | 0        |                 | MIN         | OFF          |                    |
| 769 <a href="#">(b)</a> | 0        |                 | MAJ         | OFF          |                    |
|                         |          |                 |             |              |                    |

Notes:

- a. **Error Type 513:** the survivable processor (Survivable Core Server or Survivable Remote Server) is unregistered. Possible causes include:
  - 1 The main server is down.
  - 1 The network is down.
  - 1 The server or survivable processor administration is incorrect.
- b. **Error Type 769:** invalid or wrong NIC address. Unable to access the IP address of the native NIC. Use the Maintenance Web Page to verify/configure the NIC address (**Server Configuration -> Configure Server -> Configure Individual Services -> Configure Interfaces**).

## STRAT-3 (Stratum-3 Clock)

S8700-series Fiber-PNC only

| MO Name in Log | Alarm Level | Initial Command to Run            | Full Name of MO |
|----------------|-------------|-----------------------------------|-----------------|
| STRAT-3        | MAJ<br>MIN  | <code>test synchronization</code> | Stratum-3 clock |

The *Digital Synchronization Network Plan (PUB 60110)* specifies a hierarchy of synchronization nodes consisting of Strata 1 to 4, where the public network's sole Stratum-1 clock is the most accurate. Release 5r and later systems support both Stratum-3 and -4 operations. See [Stratum-4 Synchronization](#) for details on Stratum-4 operation.

A Stratum-3 clock derives its timing from two DS1 references connected to a Stratum-3 or better source. The Stratum-3 clock provides a holdover of at least 24 hours should both DS1 references fail. After 24 hours, the Stratum-3 clock still provides service but its accuracy may be degraded. The *Digital Synchronization Network Plan (PUB 60110)* requires that the Stratum-3 clock have duplicated components.

The Stratum-3 clock can be configured with only one DS1 input if one of the Clock Input cards is removed. Also, the Stratum-3 clock can free run (use its internal clock without using DS1 inputs, if both Clock Input cards are removed).

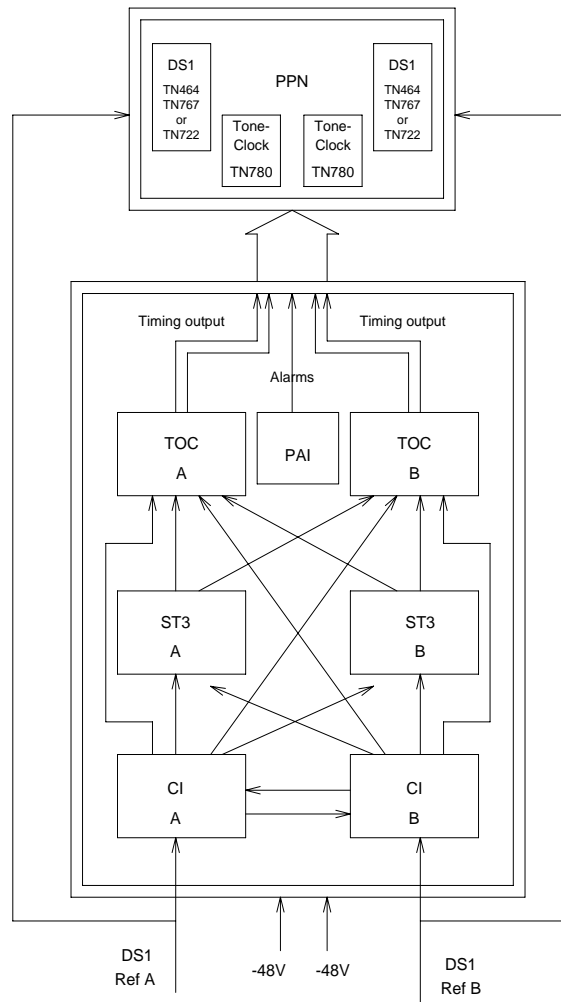

Only a TN780 Tone-Clock circuit pack recognizes and supports a Stratum-3 clock and its alarm signals. The TN780 Tone-Clock circuit pack is also backward-compatible with a TN768 Tone-Clock circuit pack. The Stratum-3 clock may be connected to a non IPSI PN where a TN780 Tone-Clock circuit pack resides. The Stratum-3 clock should never be connected to an IPSI connected PN.

The only operation that software can perform is a query of the alarm leads. The only recovery action that can be performed on a catastrophic failure of the Stratum-3 clock is using the local oscillator on the active TN780 Tone-Clock circuit pack. Neither software nor the TN780 Tone-Clock circuit pack can request additional information about the health of the Stratum-3 clock other than the information provided by the alarm leads. Furthermore, neither the software nor the TN780 Tone-Clock circuit pack can request that the external clock switch references, change configuration, disable/enable, initialize, and so forth.

In the system, the Stratum-3 clock has been implemented as an external which follows the specification in PUB 60110 for Stratum 3. The only external Stratum-3 clock that is supported is the Telecom Solutions Digital Clock Distributor for Customer Premise Timing (DCD-CPT) Stratum-3 clock. [Figure 73: Stratum-3 Clock Hardware Configuration](#) shows how the Stratum-3 hardware configuration provides clock and alarm signals to the TN780 Tone-Clock circuit pack(s). The reference DS1 facilities connect directly to the Stratum-3 clock for timing purposes, but the DS1 data may be routed into the switch by using a Y connector (H-600-274 G1 for the 50-pin DS1 end or H-600-274 G2 for the 15-pin DS1 end).

For more information about installing a Stratum-3 clock, refer to *Maintenance for the Avaya S8700 Media Server with an Avaya SCC1 Media Gateway or an Avaya MCC1 Media Gateway*.

**Figure 73: Stratum-3 Clock Hardware Configuration**

---

## Stratum-3 Clock LED Strategy

**Note:**

When looking in the Stratum-3 cabinet, “A” card is on the left and “B” card is on the right.

The normal LED scheme is not followed for this device. Green LEDs do not indicate maintenance activity. There are no yellow LEDs, and there are more than three LEDs per circuit pack.

Removal of a card in the Stratum-3 clock may cause alarm(s) to be resolved and the query test to pass. However, the removed cards should still be replaced to restore the Stratum-3 clock to full service.

The Stratum-3 clock has the following components:

1 2 Clock Input cards (CI)

Provides the logic to select the better DS1 reference or Clock Input card. The red FAIL LED on this card indicates a failure with the card or the DS1 reference connected to it.

1 2 Stratum-3 Cards (ST3)

Provides 24-hour holdover. The red FAIL LED on this card indicates a failure with the card. Replace the card.

1 2 Timing Output Cards (TOC)

Provides cable length compensation, multiple output ports, selection of the ST3, and CI outputs. This type of card has two red failure LEDs: one indicates a failure of the card, the other indicates a failure in one or more output ports. In either case, replace the card.

1 1 PBX (Private Branch Exchange) Alarm Interface (PAI)

Filters power supplied to the clock, provides fuse protection, and provides alarm indications based on inputs supplied by other cards. The six LEDs on this card provide indications for the six alarm or status conditions as follows:

- Loss of DS1 reference A
- Loss of DS1 reference B
- Loss of one clock unit
- Loss of both clock units
- Loss of one power supply
- Loss of both power supplies

The output of the CI and PAI cards go directly to the TN780 Tone-Clock circuit pack via two 25-pair amphenol terminated cables. Every card has red and/or green LEDs for providing status or alarm indications. The abbreviations used in the table are defined above except for SRC (source) and PLL (Phase Locked Loop).

**Table 240: Stratum-3 Clock LED Indications**

| Card | Name       | Color | Indication                                    |
|------|------------|-------|-----------------------------------------------|
| PAI  | REF A      | Red   | Loss of input reference A or CI A failed      |
|      | REF B      | Red   | Loss of input reference B or CI A failed      |
|      | ST A       | Red   | Failed Stratum-3 clock A                      |
|      | ST B       | Red   | Failed Stratum-3 clock B                      |
|      | PWR A      | Green | -48VDC A present                              |
|      | PWR B      | Green | -48VDC B present                              |
| CI   | FAIL       | Red   | Card failure                                  |
|      | DS1        | Green | DS1 source present                            |
|      | CC         | Green | Composite clock source <sup>1</sup> present   |
|      | SRC ACTIVE | Green | Card is currently on-line                     |
| ST3  | FAIL       | Red   | Card failure                                  |
|      | LOCK       | Red   | PLL lost sync with reference or holdover mode |
|      | REF A      | Red   | Timing Reference from CI A                    |
|      | REF B      | Red   | Timing Reference from CI B                    |
| TOC  | FAIL       | Red   | Card failure                                  |
|      | PORT ALM   | Red   | Output port alarm (one or more)               |
|      | ST         | Green | Reference present from ST clock               |
|      | INPUT      | Green | Reference present from CI                     |
|      | 500'       | Green | 500-foot phase advance                        |
|      | 1000'      | Green | 1000-foot phase advance                       |

1. Composite Clock (CC) source refers to the protocol used to electrically transfer timing from the Stratum-3 clock to the switch. The Composite Clock source is not relevant to the system.

## Error log entries and recommended actions

Table 241: STRAT-3 Error Log Entries

| Error Type | Aux Data | Associated Test                    | Alarm Level   | On/Off Board | Recommended Action       |
|------------|----------|------------------------------------|---------------|--------------|--------------------------|
| 0 (a)      | 0        | Any                                | Any           | Any          | test synchronization r 4 |
| 1 (b)      | Any      | Stratum-3 Clock Alarm Query (#649) | MIN           | OFF          | test synchronization r 4 |
| 18 (c)     | 0        | disable sync                       | WRN           | OFF          | enable sync              |
| 257 (d)    | Any      | Stratum-3 Clock Alarm Query (#649) | MIN           | OFF          | test synchronization r 4 |
| 513 (e)    | Any      | Stratum-3 Clock Alarm Query (#649) | MIN           | ON           | test synchronization r 4 |
| 769 (f)    | Any      | Stratum-3 Clock Alarm Query (#649) | MIN           | ON           | test synchronization r 4 |
| 1025 (g)   | Any      | Stratum-3 Clock Alarm Query (#649) | MIN<br>MAJ () | ON           | test synchronization r 4 |
| 1281 (h)   | Any      | Stratum-3 Clock Alarm Query (#649) | MIN<br>MAJ () | ON           | test synchronization r 4 |
| 1537 (i)   |          |                                    | MIN<br>MAJ () | ON           |                          |
| 1793 (j)   |          |                                    | MIN<br>MAJ () | ON           |                          |

Notes:

- a. **Error Type 0:** Run the short test sequence first. If every test passes, run the long test sequence. Refer to each test's description, and follow its procedures.
- b. **Error Type 1:** this Error Type corresponds to FAIL code 1 of the [Stratum-3 Clock Alarm Query \(#649\)](#): Either reference A failed or the CI card A failed.
- c. **Error Type 18:** Synchronization Maintenance was disabled with `disable synchronization-switch`.
  1. Enter `enable synchronization-switch` to enable Synchronization Maintenance reference switching and to resolve this alarm.
- d. **Error Type 257:** this Error Type corresponds to FAIL code 2 of the [Stratum-3 Clock Alarm Query \(#649\)](#): one power supply failed.
- e. **Error Type 513:** this Error Type corresponds to FAIL code 4 of the [Stratum-3 Clock Alarm Query \(#649\)](#): one clock unit failed.

- f. **Error Type 769:** this Error Type corresponds to FAIL code 8 of the [Stratum-3 Clock Alarm Query \(#649\)](#): either reference B failed or the CI card B failed.
- g. **Error Type 1025:** this Error Type corresponds to FAIL code 16 of the [Stratum-3 Clock Alarm Query \(#649\)](#): every power supplied failed.

A Minor alarm results if the Stratum-3 clock can still provide timing to the switch; otherwise, a Major alarm will be raised because the Stratum-3 clock is not providing timing and the switch is referencing the local oscillator on the TN780 Tone-Clock circuit pack. If only the active TN780 Tone-Clock circuit pack is faulty, the standby TN780 Tone-Clock circuit pack becomes active and remains synchronized to the Stratum-3 clock. When the system switches to the standby Tone-Clock circuit pack, the alarm is resolved, and a TDM-CLK alarm is raised to indicate a possible problem on the TN780 Tone-Clock circuit pack.

If the alarm is MINOR:

1. Look for a red LED on either or both TOC cards.
2. If there is a red LED, replace the card. If there is no red LED, use the *Stratum-3 Wiring Guide*, and check that the wiring installation is correct.
3. After replacing the card or correctly rewiring the installation, clear the alarm by entering `disable synchronization-switch`, followed by `enable synchronization-switch`. The latter procedure causes synchronization software to switch back to using the Stratum-3 clock again.
4. Wait 2 minutes and run `status synchronization`.
5. If **Maintenance Name** on the status screen shows “STRAT-3,” the problem is resolved.

 **CAUTION:**

The `disable synchronization-switch` command followed by `enable synchronization-switch` may cause slip alarms. The circuit packs that can experience slips and the associated error log entry for slips are listed in [Table 242: Timing Slip Error Types](#).

**Table 242: Timing Slip Error Types**

| Circuit Pack Name     | Error Log Name | Error Log Number of Slips |
|-----------------------|----------------|---------------------------|
| DS1 Interface         | DS1-BD         | 3073 to 3160              |
| Expansion Interface   | EXP-INTF       | 2305                      |
| Switch Node Interface | SNI-BD         | 1537                      |
| Tone-Clock            | TDM-CLK        | 1025                      |
| UDS1 Interface        | UDS1-BD        | 3073 to 3160              |

If the alarm is MAJOR:

- 1 Check connections between the Stratum-3 clock and the switch.
- 1 If there are no loose connections, use the *Stratum-3 Wiring Guide* and check that the wiring installation is correct.
- 1 After reconnecting the loose connection or correctly rewiring it, clear the alarm by entering `disable synchronization-switch`, followed by `enable synchronization-switch`.
- 1 Wait 1 minute, then run `status synchronization`.
- 1 If **Maintenance Name** on the status screen shows "STRAT-3," then the problem is resolved.

If the Standby Tone-Clock circuit pack became active:

- 1 Check the connection between the Stratum-3 clock and the TN780 Tone-Clock circuit pack from which the system has just switched.
- 1 If there are no loose connections, then, replace the circuit pack containing the TN780 Tone-Clock circuit pack.
- 1 Before switching back to the new TN780 Tone-Clock circuit pack, use `test tone-clock location long` to check that the Tone-Clock is receiving a signal from the Stratum-3 clock.
- 1 If every test passes, switch to the new Tone-Clock circuit pack using `set tone-clock location override`.
- 1 If Test #651 fails, then the original TN780 Tone-Clock circuit pack should be reinserted, and the cable between the Stratum-3 clock and the TN780 Tone-Clock circuit pack should be replaced.
- 1 If Test #651 continues to fail, then escalate the problem.
- 1 If slip alarms exist after following the repair procedures for any of the previous cases, clear the slip alarms by running `test board clear`. See [Table 242: Timing Slip Error Types](#) for a list of circuit packs and associated slip error log entries.
- 1 This error indicates that the Tone-Clock circuit pack in the master port network is not a TN780. If duplicate Tone-Clock circuit packs exist in the master port network, this error may mean that one or both Tone-Clock circuit packs are not TN780s. Verify that the Tone-Clock(s) in the master port network are TN780s.

h. **Error Type 1281:** this Error Type corresponds to FAIL code 32 of the [Stratum-3 Clock Alarm Query \(#649\)](#): every clock unit failed.

i. **Error Type 1537:** An OFF-BOARD alarm on the Stratum-3 clock, indicates a DS1 facility problem; an ON-BOARD alarm indicates a fault in either the Stratum-3 clock or the connection between the Stratum-3 clock and the switch. If the Stratum-3 clock cot be referenced and the local oscillator on the TN780 Tone-Clock circuit pack must serve as the reference, a Major alarm is raised. Otherwise, a Minor alarm is raised.

- j. **Error Type 1793:** this error can be caused by one of the following conditions:
- 1 One or both TOCs (Timing Output Cards) has failed.
  - 1 The connection between the Stratum-3 clock and the TN780 Tone-Clock circuit pack is faulty.
  - 1 The TN780 Tone-Clock circuit pack is defective.

---

## Demand test descriptions and error codes

The test `synchronization` command also runs the [Synchronization Update Test \(#417\)](#).

| Order of Investigation                             | Short Test Sequence | Long Test Sequence | D/ND            |
|----------------------------------------------------|---------------------|--------------------|-----------------|
| <a href="#">Stratum-3 Clock Alarm Query (#649)</a> | X                   | X                  | Non-Destructive |

## SVC-SLOT (Service Slot)

| MO Name  | Alarm Level | Initial Command to Run | Full Name of MO |
|----------|-------------|------------------------|-----------------|
| SVC-SLOT | MIN         | none                   | Service Slot    |

The Service Slot MO detects the insertion of an invalid circuit pack into a dedicated SERVICE slot. The SERVICE slot is the left-most slot in the J58890BB port carrier, and is identified as slot location "00" in commands and screen fields.

Because this slot does not provide tip and ring connectivity to the wall field, only the following circuit packs are allowed:

- 1 TN744 Call Classifier
- 1 TN750 Integrated Announcement
- 1 TN771 Maintenance/Test
- 1 TN725 Speech Synthesizer
- 1 TN433 Speech Synthesizer
- 1 TN457 Speech Synthesizer
- 1 TN748 Tone Detector
- 1 TN420 Tone Detector

When another circuit pack is inserted in a SERVICE slot, a MINOR alarm is generated against the Service Slot MO. Instead of the illegal circuit pack's MO name, the "Service Slot" MO name is used to prevent any attempt to assign a port to the illegal pack physically residing in the SERVICE slot.

---

## Error log entries and recommended actions

Table 243: SVC-SLOT Error Log Entries

| Error Type | Aux Data | Associated Test | Alarm Level | On/Off Board | Recommended Action |
|------------|----------|-----------------|-------------|--------------|--------------------|
| 600 (a)    |          | None            | MIN         | ON           |                    |

Note:

- a. An invalid circuit pack was inserted in slot 00, the SERVICE slot, of a J58890BB port carrier. See the list of valid circuit packs.
  1. To see the invalid circuit pack's TN code, enter **list configuration board location** where *location* specifies the cabinet number, the carrier letter, and the slot number (always 00) of the alarmed circuit pack.
  2. To retire the alarm, remove the invalid circuit pack.

## SYNC (Port Network Synchronization)

| MO Name in Log | Alarm Level | Initial Command to Run            | Full Name of MO              |
|----------------|-------------|-----------------------------------|------------------------------|
| SYNC           | MIN         | <code>display errors</code>       | Port Network Synchronization |
|                | WRN         | <code>test synchronization</code> |                              |

This section discusses synchronization problems local to the switch.

Synchronization maintenance is composed of both hardware and software components, and its purpose is to provide a common reference frequency for reliable digital communications between an servers and other PBXs, central offices (COs), or customer-premises equipment (CPE). Synchronization is implemented using several system components including:

- 1 TN2312 IPSI
- 1 TN722, TN767, and TN464 DS1 Interfaces (all suffixes)
- 1 **S8700-series Fiber-PNC**: TN768, TN780, or TN2182 Tone-Clock
- 1 **S8700-series Fiber-PNC**: TN572 Switch Node Clock
- 1 **S8700-series Fiber-PNC**: TN573 Switch Node Interface
- 1 **S8700-series Fiber-PNC**: TN570 Expansion Interface

**Note:**

If both a primary and secondary reference are administered for Stratum-4 synchronization, both references must reside in the same port network (PN).

---

### **S8700-series Fiber-PNC**

---

## Traditional Sync Operation

For an S8700 Server Fiber-PNC system, synchronization is obtained from the public circuit-switched network through:

- 1 A DS1 or BRI interface
- 1 The ATM network

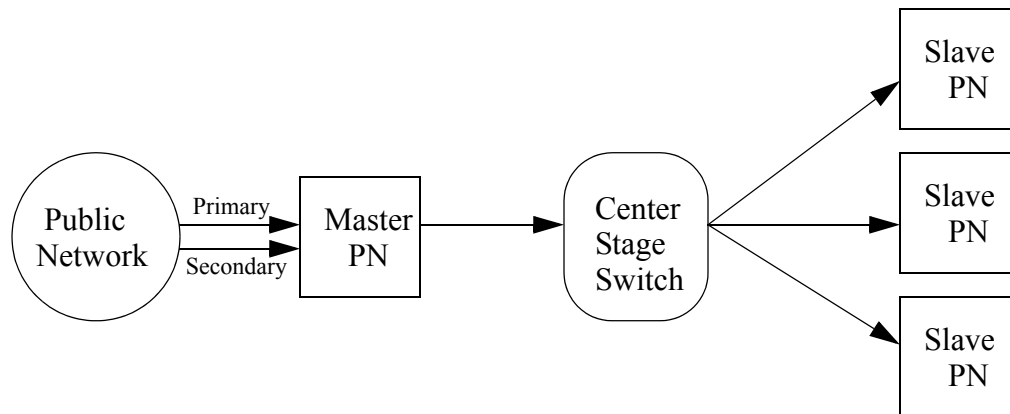

For DS1- or BRI-based synchronization, a particular DS1 or PRI interface is configured as the synchronization reference. The IPSI/Tone-Clock board in the same PN locks on to this reference and regenerates clock signals that are placed on the PN's backplane. In turn, the Center Stage Switch (CSS) components transfer this timing to every other PN. These IPSI/Tone-Clocks then regenerate clock signals for their own PNs at the same rate as the:

- 1 Master PN
- 1 Public network

This creates a hierarchy where the master PN receives timing from the public network, and every other PN derives its timing from the master through the CSS. See [Figure 74: Traditional Sync Operation](#).

---

**Figure 74: Traditional Sync Operation**

---

Typically, a pair of interfaces from the public network are configured — one as a primary and one as a secondary. The IPSI/Tone-Clock in the Master PN can:

- 1 Lock onto either interface
- 1 Switch between them in the event of a failure

In the event of a dual failure, the Tone-Clock in the master PN can generate its own timing and keep every PN synchronized. However, these PNs would not be synchronized with any other public-network interfaces that exist in any of the PNs.

When a center stage is implemented via an ATM network, it is possible to obtain timing from the ATM network. For more information, See [ATM-SYNC \(ATM Synchronization\)](#).

---

### S8700-series IP-PNC

## S8700-series IP-PNC Server Sync Operation

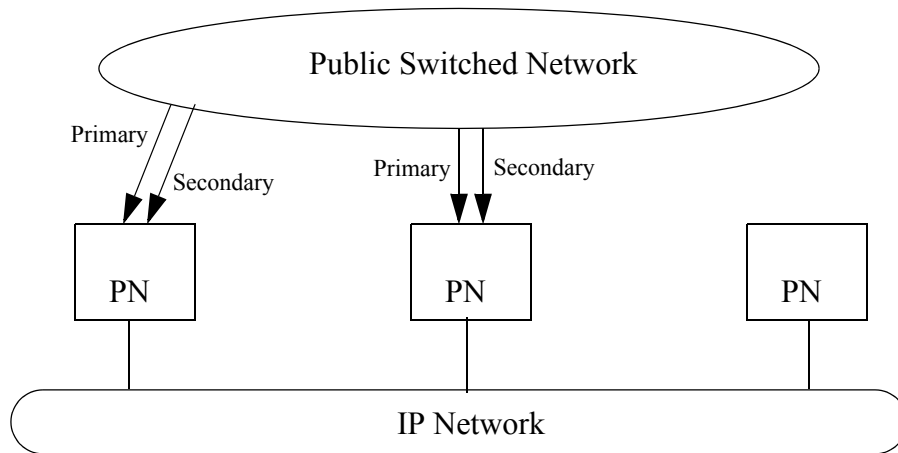

For an S8700 IP-PNC system, its port networks (PNs) are connected via the customer's IP network. This network can be used to transmit timing information between the PNs. The complete set of PNs need not be synchronized with each other. Inter-PN bearer traffic is carried as VOIP, while the Media Processors' internal jitter buffers deal with differences in transmission rates.

Synchronization is needed for a PN with a public-network digital interface. Each PN with a DS1 or trunk-side BRI interface must be synchronized with an external timing source to prevent slips between that PN and the external circuit-switched network. Each PN needs to operate independently. Each PN:

- 1 Potentially needs its own external synchronization reference
- 1 Is always locked to an external public-network interface or is running locally.

A typical S8700 IP-PNC configuration is shown in [Figure 75: S8700 Server IP-PNC Sync Operation](#).

**Figure 75: S8700 Server IP-PNC Sync Operation**

This figure also shows the far-right S8700 IP-PNC system's PN without public-network digital interface. A PN without public-network connectivity runs off of its local IPSI circuit pack's Tone-Clock circuit.

## Clock Synchronization

**Note:**

**S8700-series Fiber-PNC:** Stratum-3 clocking is not available for a PN where the Tone-Clock function is supplied by either a:

- 1 TN2312 IPSI circuit pack's Tone-Clock circuit
- 1 TN2182 Tone-Clock circuit pack

This section discusses synchronization with Stratum-3 and -4 clocking devices.

## Stratum-3 Synchronization

Since the clock module on the TN2312 does not support synchronization with an external Stratum-3 clocking device, you may provide Stratum-3 clocking for a S8700 Server system by using the TN780 Tone-Clock circuit pack in a non IPSI connected port network. To bring in the external Stratum-3 clocking signals into the TN780, a processor carrier is needed. This new PN control carrier will replace the processor carrier in the old PPN converted to PN 1. The Stratum-3 clocking must come into Port Network #1 because the S8700 Fiber-PNC software has the Stratum-3 clocking hard-coded to this port network.

---

## Stratum-4 Synchronization

The system can be configured with primary and secondary synchronization references (DS1 or UDS1 Interface circuit packs) when using Stratum-4 synchronization. If this is the master synchronization source for the network, then its local oscillator is used and no DS1s are used as references.

If this system is a slave in the network, a primary reference must be used as the synchronization reference and a secondary reference is optional:

- 1 If the primary synchronization reference is not providing a valid timing signal, the system automatically switches to the secondary synchronization reference.
- 1 If the primary synchronization reference is invalid and secondary reference does not provide a valid timing signal or is not administered as a synchronization reference, an IPSI's Tone-Clock circuit or a Tone-Clock circuit pack provides the PN's timing source.
- 1 If the system is using the local oscillator as the timing source (both the primary and secondary references are providing invalid timing signals), should either the primary or secondary reference becomes valid again, the system (PN for S8700 Server systems) switches back to the primary or secondary source.
- 1 When both the primary and secondary source become valid, the system switches to the primary source, since the primary source is always preferred over the secondary source when both sources are equally healthy.

---

## Synchronization Troubleshooting

For Stratum-4 operation, major and minor alarms indicate that there is a problem with the system synchronization references. These alarms will be resolved when the alarmed synchronization reference is restored.

The `change synchronization` command allows primary and secondary references to be administered per cabinet.

Use `status synchronization` to show the current synchronization reference per cabinet. Use `display synchronization` or `list synchronization` to show the primary and/or secondary synchronization references that are administered.

Other commands associated with Synchronization Maintenance are `disable synchronization-switch` and `enable synchronization-switch`. These commands disable the ability of Synchronization Maintenance to switch between synchronization references and to enable this switching ability, respectively. Use `set synchronization` only after synchronization has been disabled, to manually switch to a specific synchronization reference. Use `set synchronization` to help diagnose synchronization problems by forcing a specific reference (DS1, UDS1, or Tone-Clock) to be the system synchronization reference to determine if a specific reference is providing a valid timing signal.

## Troubleshooting Approach

Slip errors are the primary symptom associated with being un-synchronized.

A correct Synchronization plan for the network keeps the systems within the network transmitting data at approximately the same rate to avoid situations where:

- 1 One system transmits data at a rate faster than another system can receive the data (in which case data is lost).
- 1 One system transmits data at a rate slower than another system expects to receive data (in which case data is repeated).

Either of these situations, data being lost or repeated, is a slip.

When troubleshooting synchronization problems when slips are the primary error log entry indications of a synchronization problem, requires that the problem be isolated to:

- 1 A problem outside of the switch (That is, the switch is not properly synchronized to the rest of the network.)
- 1 A problem internal to the switch

DS1 and UDS1 circuit packs can be administered with slip detection enabled using the **Slip Detection** field set to **y** on the `add ds1` or `change ds1` administration screens (See *Administering Avaya Aura™ Communication Manager - 555-233-506*). All DS1 and UDS1 circuit packs administered as slip enabled are counted in the following algorithm:

When over half of the DS1 and UDS1 circuit packs administered as slip enabled are experiencing slips, and the primary or secondary synchronization reference is the current synchronization reference, synchronization will try the other administered synchronization reference.

In situations where one or many circuit packs in the system are experiencing slips, the problem could be with the synchronization reference, with individual circuit packs, or with phase modulation of the transmitted digital bit streams due to environmental variations of the transmission facilities (such as temperature variations that affect the electrical length of a transmission line). The circuit packs that can experience slips and the associated error log entry for slips are as follows in [Table 244](#):

**Table 244: Error Log Entries for Slip Errors**

| <b>Circuit Pack</b>   | <b>Error Log Name</b> | <b>Error Log Number of Slips</b> |
|-----------------------|-----------------------|----------------------------------|
| DS1 Interface         | DS1-BD                | 3073 – 3160                      |
| Expansion Interface   | EXP-INTF              | 2305                             |
| Switch Node Interface | SNI-BD                | 1537                             |
| circuit pack          | TDM-CLK               | 1025                             |
| UDS1 Interface        | UDS1-BD               | 3073 – 3160                      |

When slips occur on any of these circuit packs, first consult the individual circuit pack's section in this manual. If slips occur in small amounts, they may be due to environmental conditions as previously described. If no service degradation is occurring, no action is necessary. When the system switches synchronization sources, slips can be expected from DS1-BD, UDS1-BD, and EXP-INTF circuit packs. If service degradation occurs, after following the repair steps in the individual section, use the following trouble shooting techniques.

[Table 245](#) lists circuit packs that can report slips and related circuit packs whose hardware problems that cause those slips.

**Table 245: Slips and Related Circuit Packs**

| <b>Circuit Pack Reporting Slips</b>          | <b>Associated Circuit Packs that Can Cause Slips</b>                                                                               |
|----------------------------------------------|------------------------------------------------------------------------------------------------------------------------------------|
| DS1 Interface                                | Active Tone-Clock in same PN                                                                                                       |
| Expansion Interface                          | Active Tone-Clock in same PN or circuit pack at opposite end of fiber or metallic connection                                       |
| Switch Node Interface                        | Circuit pack at opposite end of fiber or metallic connection, or active Switch Node Clock circuit pack in same switch node carrier |
| IPSI's Tone-Clock or Tone-Clock circuit pack | Current DS1 reference                                                                                                              |
| UDS1 Interface                               | Active Tone-Clock in same PN                                                                                                       |

---

## Troubleshooting Synchronization Problems

The following flow chart presents a logical approach to troubleshooting synchronization problems in conjunction with the previous background information. Explanatory notes follow the charts.

**Figure 76: Synchronization Troubleshooting, Fig. 1 of 5**

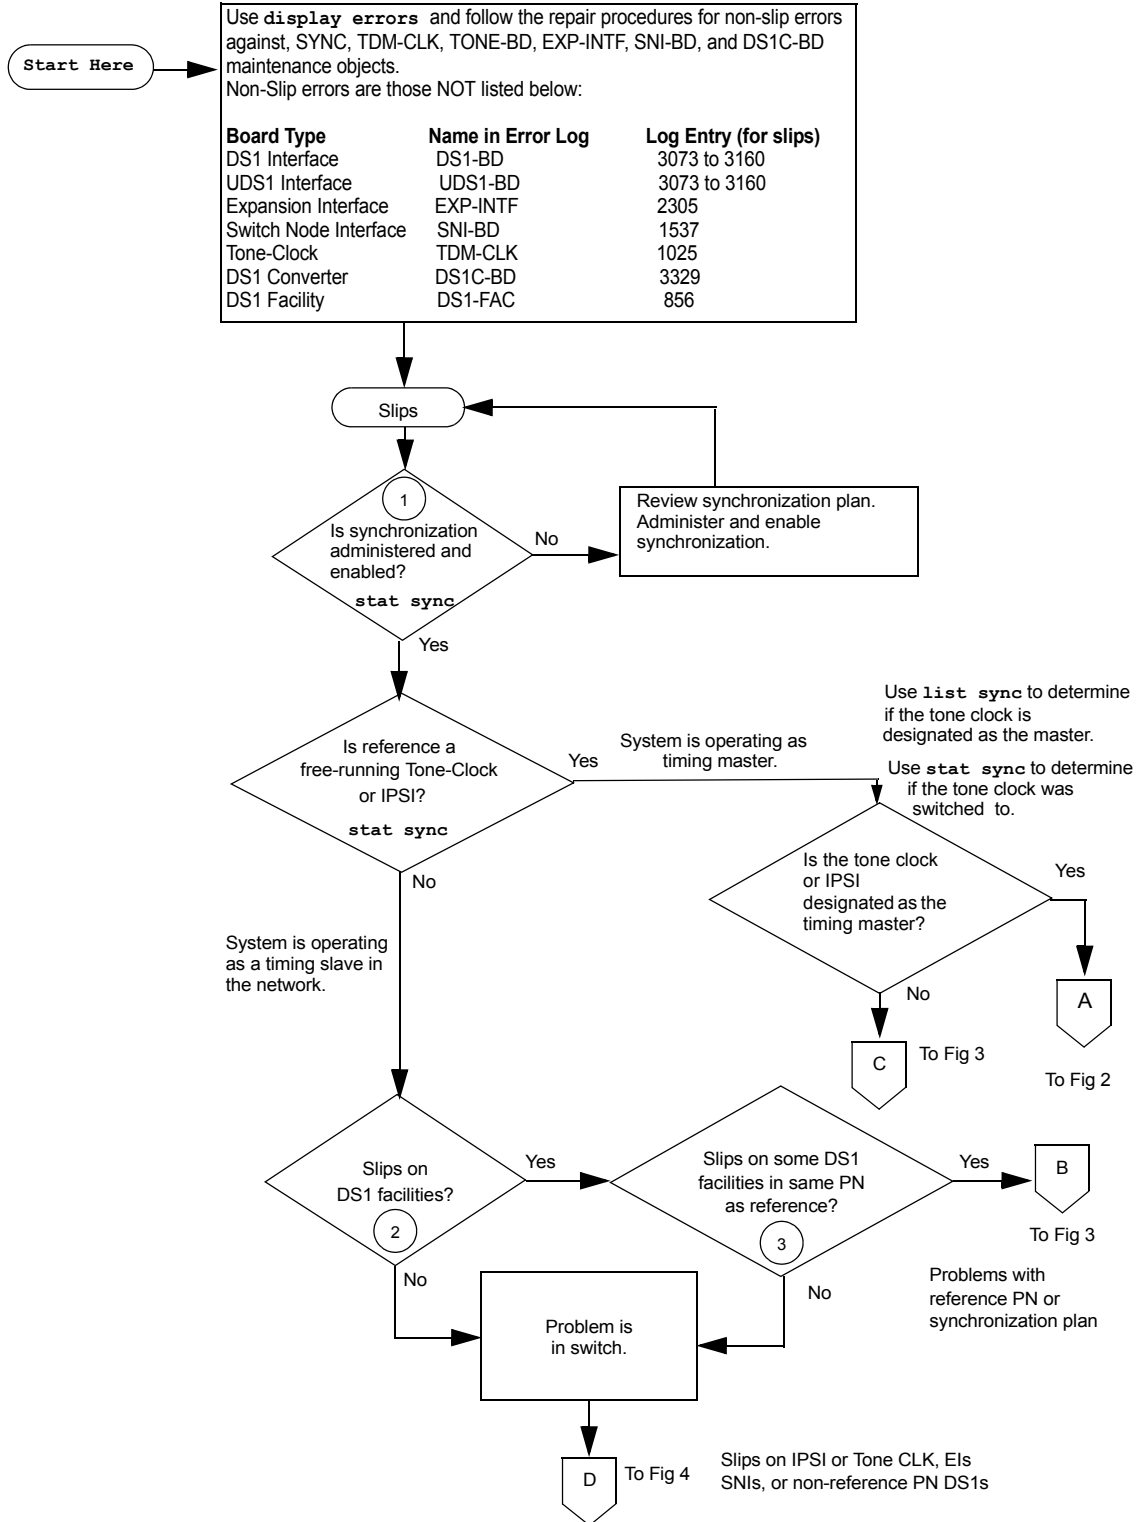

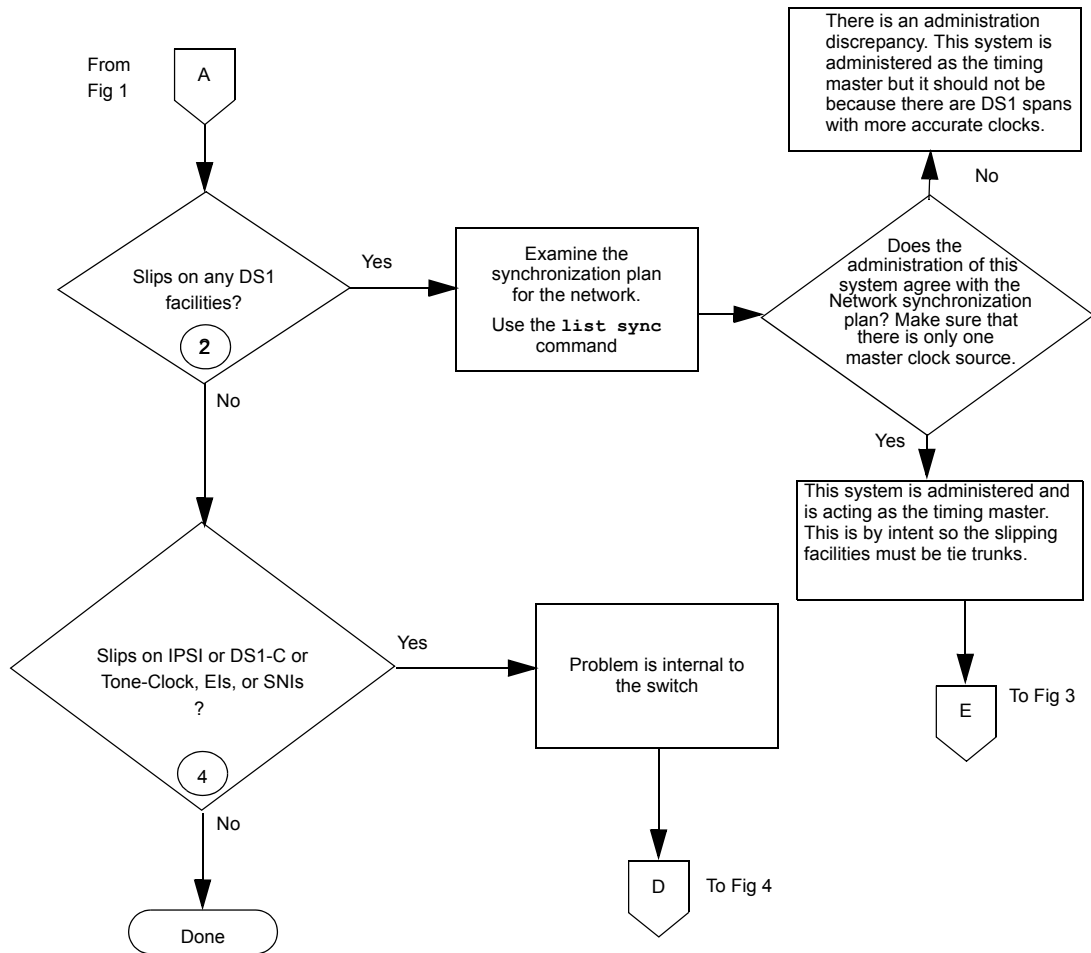

Figure 77: Synchronization Troubleshooting, Fig. 2 of 5

**Figure 78: Synchronization Troubleshooting, Fig. 3 of 5**

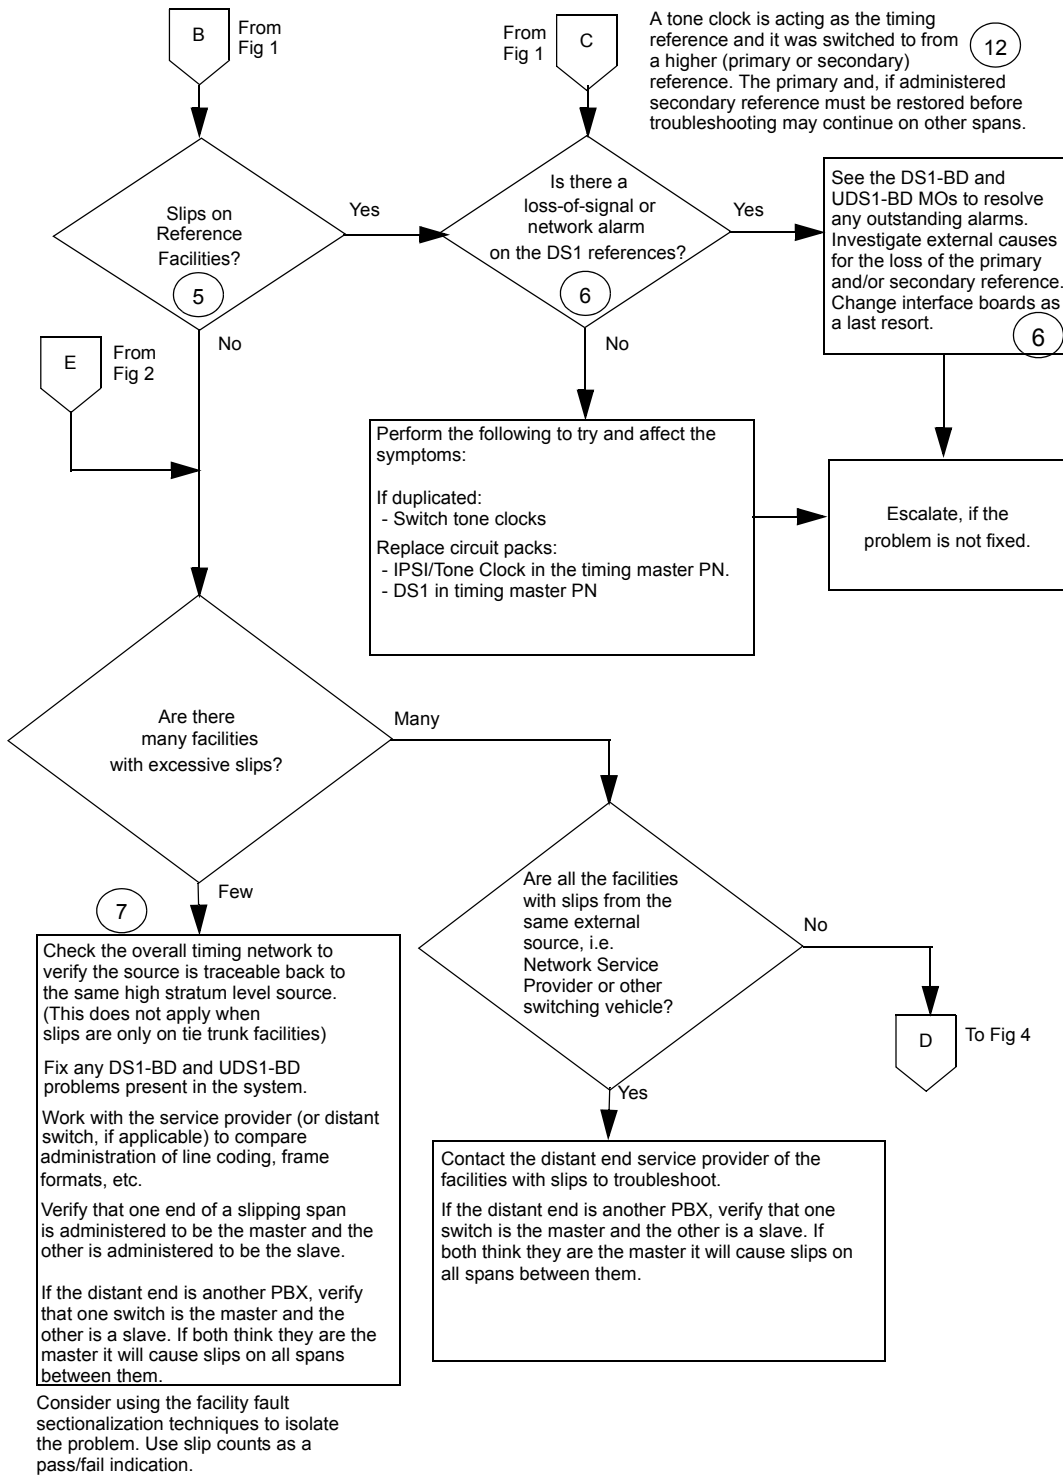

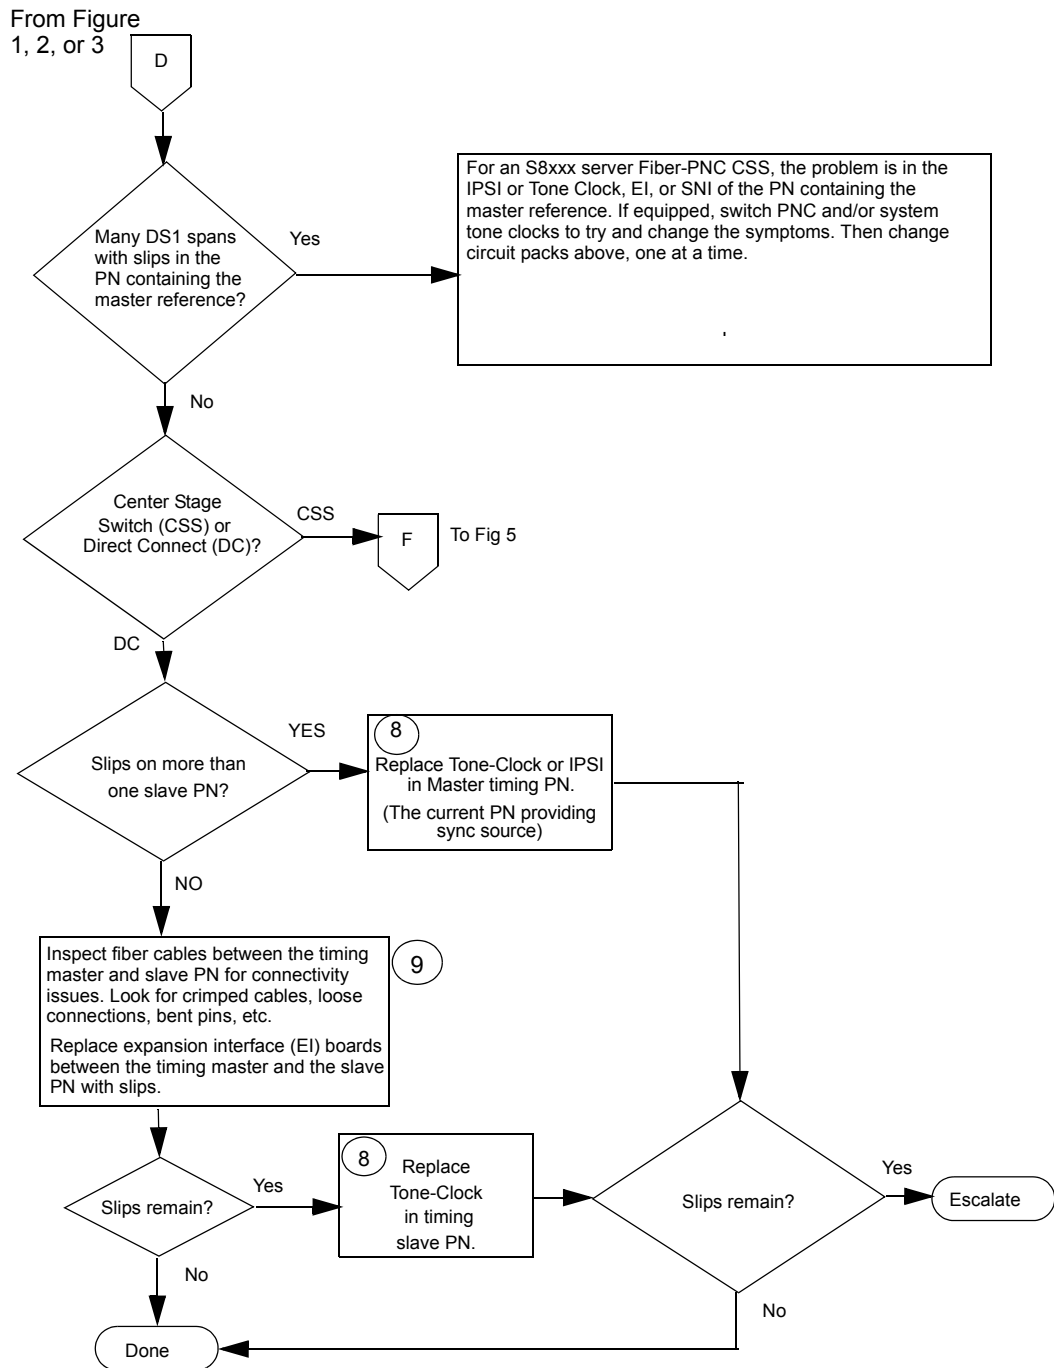

Figure 79: Synchronization Troubleshooting, Fig. 4 of 5

**Figure 80: Synchronization Troubleshooting, Fig 5 of 5**

The synchronization issue covers a large portion of the system. The problem is in a center stage switch (CSS), IPSI or Tone-Clock, EI, SNI, or DS1 spans in port networks (PN) other than the timing master PN.  
 This procedure attempts to isolate the problem.  
 When instructed to do so, perform the steps indicated while slips remain.

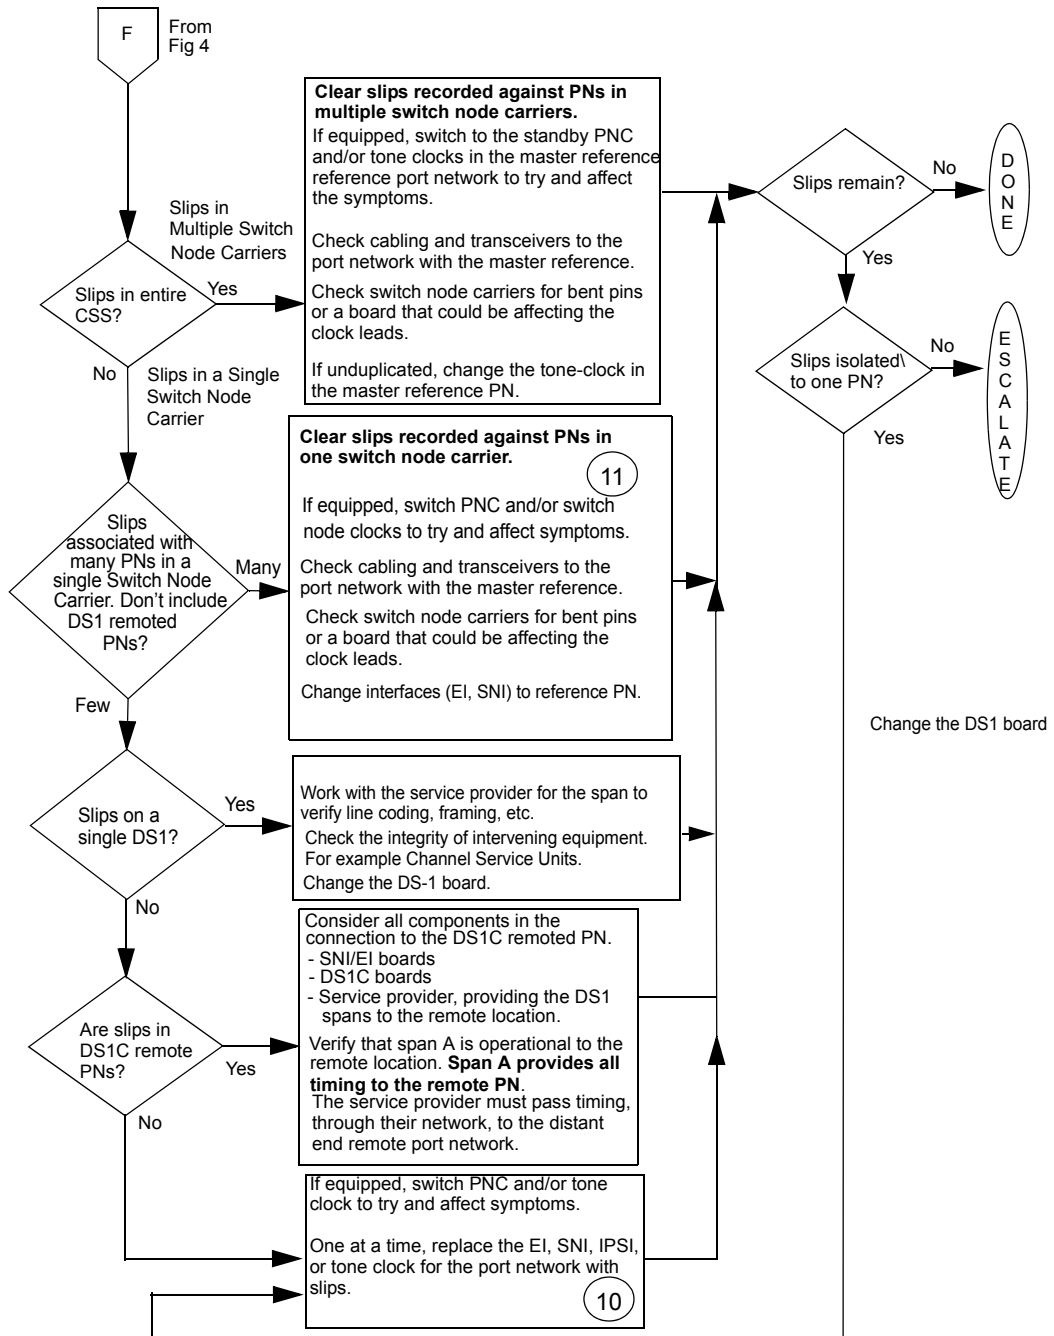

Figure 81: Synchronization Troubleshooting, Fig. 1 of 4

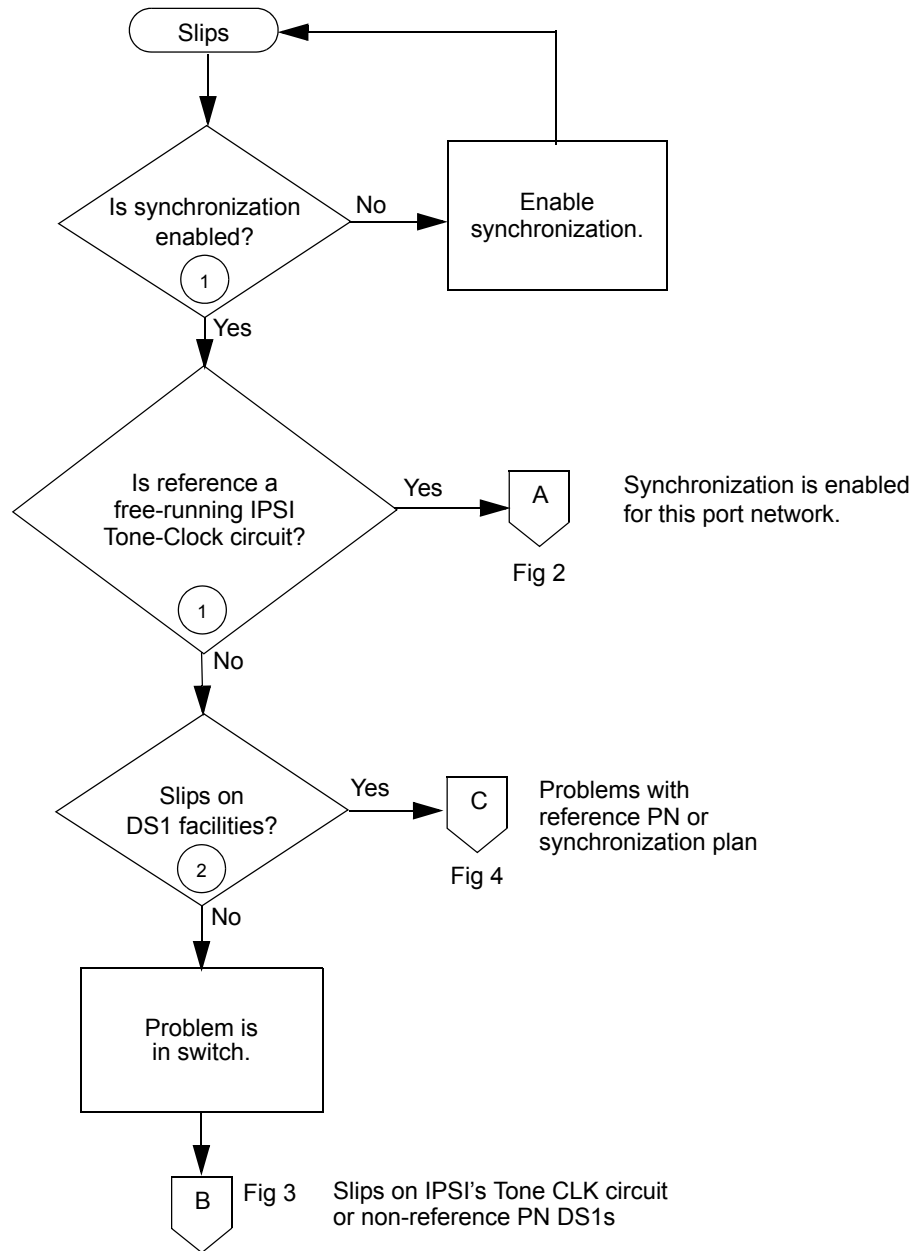

Figure 82: Synchronization Troubleshooting, Fig. 2 of 4

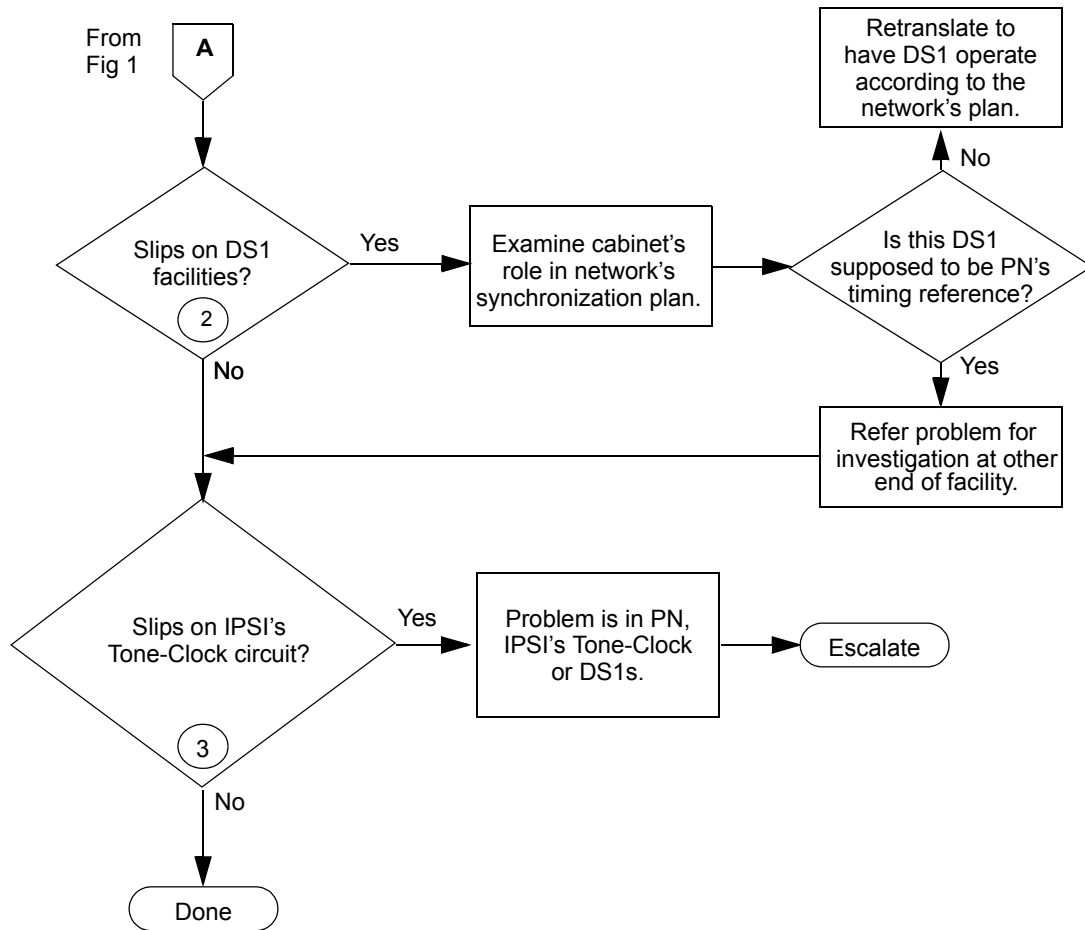

Figure 83: Synchronization Troubleshooting, Fig. 3 of 4

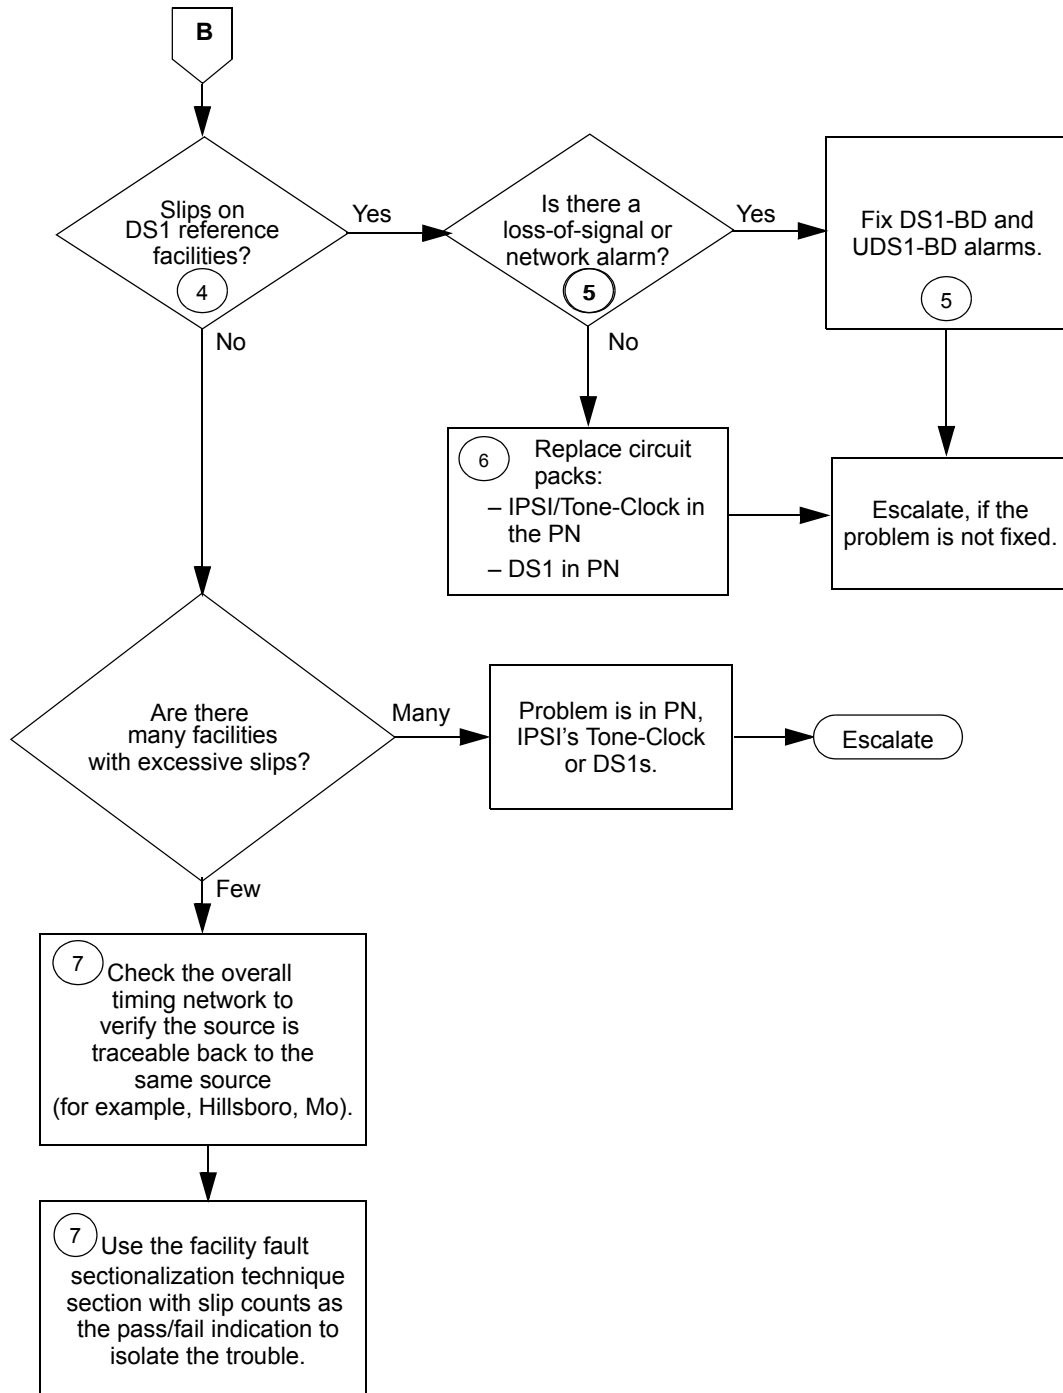

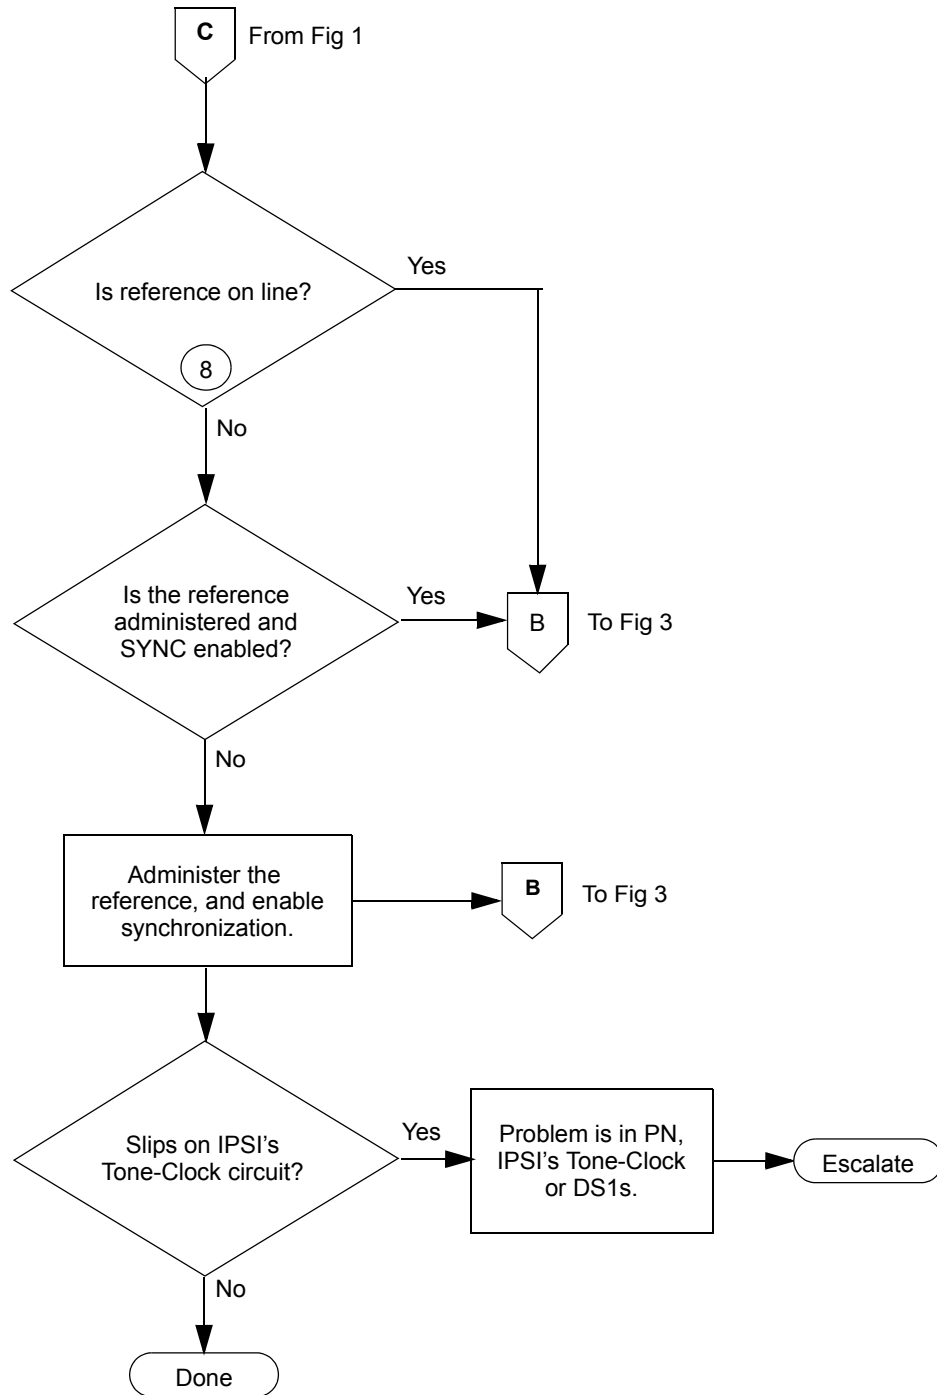

Figure 84: Synchronization Troubleshooting, Fig. 4 of 4

Notes for Sheet 1 through Sheet 5 flowcharts. (When checking for slip errors, use the previous [Table 244: Error Log Entries for Slip Errors](#).)

1. Use **status synchronization** to see if synchronization is enabled, and to determine the on-line reference. If the on-line reference is a Tone-Clock board, the switch is operating in free run mode.

If Stratum 3 is displayed, and no DS1s are connected to the Stratum-3 clock or no DS1 connection existed to the Stratum-3 clock for over 24 hours, then the Stratum-3 clock is in free run mode.

2. Check for slip errors against DS1-BD and UDS1-BD. In the error log (**display errors**) look for the following Error Types to identify slips against these board types.

| Board Type     | Error log name | Log Entry (for slips) |
|----------------|----------------|-----------------------|
| DS1 Interface  | DS1-BD         | 3073 - 3160           |
| UDS1 Interface | UDS1-BD        | 3073 - 3160           |
|                |                |                       |

For slips on either of these board types, first refer to the individual board's section in this manual. Follow the test and repair steps in those sections.

3. If Stratum 3 is administered (**display synchronization**) and on-line (**status synchronization**), check for DS1-BD or UDS1-BD slip errors for the DS1(s) or UDS1(s) used as input to the Stratum-3 clock. Check the LED indications on the Stratum-3 clock to determine which DS1 is providing input to Stratum 3, and examine the cross-connect information for that DS1.
4. Check for slips errors against EXP-INTF, SNI-BD, and TDM-CLK. In the error (**display errors**) log, look for the following Error Types to identify slips against these board types.

| Board Type            | Error log name | Log Entry (for slips) |
|-----------------------|----------------|-----------------------|
| Expansion Interface   | EXP-INTF       | 2305                  |
| Switch Node Interface | SNI-BD         | 1537                  |
| Tone Clock            | TDM-CLK        | 1025                  |
| DS1 Converter         | DS1C-BD        | 3329                  |
|                       |                |                       |

5. Check **status synchronization** for the current DS1 reference. If a DS1 or UDS1 is the on-line reference, check for slips on that DS1 or UDS1.

6. Check for LOS, Blue, Yellow, and Red alarms on the on-line reference facility, and fix those problems first. Check for slips, misframes, minor and major error rates and fix those problems next. See the DS1-BD and/or UDS1-BD for the error log entries associated with the previously mentioned alarms. Replace the circuit packs one at a time and wait at least 1 hour to determine if the problem went away. This procedure is disruptive and should be done after hours if possible.

If problems persist it may be useful to compare translations for line coding and frame formats with the far end service provider. Make sure the translations match.

If high or critical reliability switch the Port Network Connectivity (PNC) to try and help isolate the problem.

Instead of replacing the Tone-Clock circuit pack in systems where Tone-Clocks are duplicated, run `set tone-clock` to interchange Tone-Clocks. If the problem goes away, replace the previously active Tone-Clock.

7. If a few facilities experience slips or are unusable references, the clock source for facilities with slips or that are unusable is not traceable to the same ultimate source as the clock source for the on-line reference facility.

Examine the overall timing network for the interconnected DS1 to determine if the:

- 1 Clock can be traced back to a single source.
- 1 Reference designations for each location in the distribution of timing is supplied in accordance with a *synchronization plan*.

Examine the capability of the external transmission equipment to pass or provide timing.

Verify the integrity of the on-site hardware by using [Facility Fault Sectionalization](#). This:

- 1 Loops the transmit signal to the receive signal.
- 1 Verifies that the excessive slips or the unusable reference are no longer observed.

This is a time-consuming process that disrupts service. Perform it after hours if the service provided by the system is acceptable as determined by the customer.

8. For a high- or critical-reliability (duplex) system, use `set tone-clock` to interchange IPSI circuit packs' Tone-Clock circuits or Tone Clock circuit packs, as applicable. If slips go away, replace the previously active Tone-Clock or IPSI circuit pack.

For a standard reliability (simplex) system, change the tone clock.

9. Use `list fiber-links` to determine the EIs on the active PN and the EIs associated with the slave PN. If the switch does not have duplication, the EIs are all on the active PN.

10. Replace the circuit packs one at a time, and wait at least 1 hour to determine if the problem has gone away. This procedure is disruptive and should be done after hours if possible.

Instead of replacing the EI and SNI in systems where the PNC is duplicated, perform a PNC interchange using `reset pnc interchange`. If the problem goes away, replace either the EI or the SNI on the previously active PNC. Replace one at a time and make the PNC active again to see if the problem is fixed.

Instead of replacing the Tone-Clock circuit pack in systems where the Tone-Clocks are duplicated, run `set tone-clock` to interchange Tone-Clocks. If the problem goes away, replace the previously active Tone-Clock.

Also, before replacing a Switch Node Clock circuit pack, use `set switch-node-clock` if SNCs are duplicated in the carrier. If the problem goes away, replace the previously active SNC.

11. Use the following steps to disable and enable synchronization to the same source. This may, in some instances, reset where a port network gets its timing.
  - a. Use the `status synchronization` command to determine where synchronization is currently being obtained.
  - b. Use the `disable synchronization` command to temporarily disable the current synchronization source.
  - c. Use the `set synchronization` command to set synchronization source to where it was before it was disabled. See step [a](#) above.
  - d. Use the `enable synchronization` command to enable synchronization.

Verify whether or not slips continue.

12. Onsite personnel can determine whether an IPSI or Tone Clock is providing timing by observing the amber LED on the faceplate.
  - If the LED is on 75 percent of the time and off 25 percent of the time, the IPSI or Tone Clock is externally synchronized to a master clock source.
  - If the LED is off 75 percent of the time and on 25 percent of the time, the IPSI or Tone Clock is providing timing.

---

## Facility Fault Sectionalization

DS1 facility fault sectionalization involves looping around the DS1 signal at on-site access points to localize the source of the problem to equipment and wiring on either the near side or far side of the looparound point.

The facility fault sectionalization technique disrupts service. When you perform the looparound on a facility, make sure it is not the on-line synchronization reference or a system outage will occur.

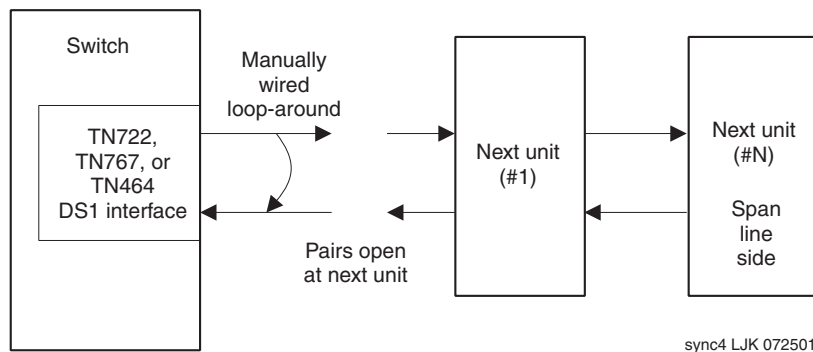

When you use this technique to investigate problems on facilities with multiplex or DACS equipment, the technique becomes cumbersome because every 64-kbps (B-Channel) or subrate channel corresponding to the DS1 facility needs to be looped around.

[Figure 85: Manual Looparound for Facility Fault Sectionalization](#) shows a sequence of units (1 though n) that may be connected as the on-site equipment. A typical example is the case where the only on-site equipment is channel-terminating equipment designated Unit #1. A more complex, less typical example might have a DACS as Unit #1, a protection switch as Unit #2, and a DS1-level microwave radio system as Unit #3.

The flowchart in [Figure 86: Facility Fault Sectionalization](#) gives an overview of the facility fault sectionalization technique. It is important that you know the configuration and wiring of the equipment for the problem facility in order to support this technique.

---

**Figure 85: Manual Looparound for Facility Fault Sectionalization**

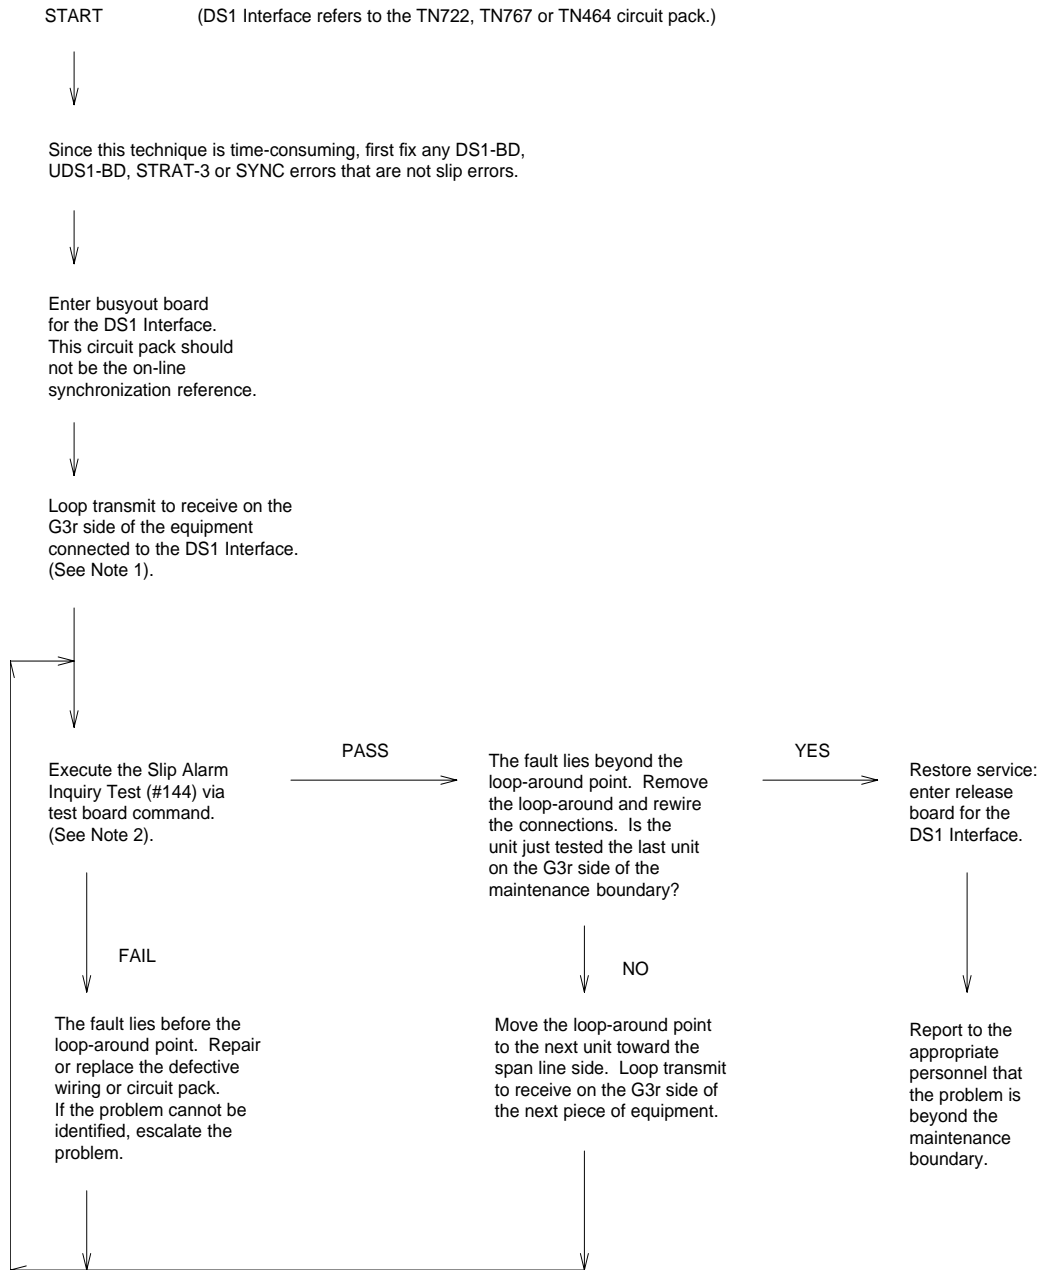

---

Since the technique is time consuming, fix any [DS1-BD \(DS1 Interface Circuit Pack\)](#), [UDS1-BD \(UDS1 Interface Circuit Pack\)](#), [STRAT-3 \(Stratum-3 Clock\)](#), or [SYNC \(Port Network Synchronization\)](#) errors first that are not slip errors.

**Figure 86: Facility Fault Sectionalization**

## Notes to Facility Fault Sectionalization Flowchart

1. Loop transmit to receive on the system side.

Remove the transmit signal from the TN722, TN767, or TN464 circuit pack inputs and outputs and loop it around to the receive signal going toward the TN722, TN767, or TN464 circuit pack at the first unit wired to the TN722, TN767, or TN464 circuit pack.

The looparound signal may take different forms depending on the installation.

- 1 In some cases, the unit connected to the system may provide a switch or a terminal interface to control the desired looparound. Make sure that the signal is looped toward the system and that the timing signal is looped.
- 1 In most cases, it may be necessary to temporarily rewire connections at the cross-connect fields to loop the signal back toward the switch.

The point at which the signal is looped should be one at which physical access is easy and where the signal level is within the line compensation (i.e. equalization) range of the hardware connected. A few cases exist where access to the looparound can be easily provided at locations where the signal level is within the line compensation range of the hardware. Use `change ds1 location` to change the line compensation.

2. Execute `test board location` for the TN722, TN767 or TN464. Look at results of Test #144, the Slip Alarm Inquiry test. When this test fails, the error code gives the number of slips detected since the last Slip Inquiry test was run. If the test fails, run it at least one more time to ensure that slips have occurred since the looparound was installed.

## Timing Loops

A timing loop exists when a system receives timing from another system whose timing reference is directly or indirectly derived from itself. The system synchronization planner *must avoid creating a timing loop* when administering the synchronization references in a system. Timing loops can lead to loss of digital data between systems that are exchanging data with any system within the loop. An invalid timing signal will also be generated by any system within the loop, thus propagating the invalid timing signal to any system(s) using a system within the loop as a synchronization reference.

A correctly designed network has no loops, and each piece of equipment in the network is supplied by a clock with an equal or lower stratum number. (For example, the inputs to a Stratum-3 clock should never be from a Stratum-4 device.)

**⚠ CAUTION:**

Synchronization administration changes should never be done without consulting the network's overall synchronization plan. If you suspect that synchronization administration changes are needed, follow normal escalation procedures.

### Synchronization Switches away from Current Timing Reference

Synchronization changes away from a DS1 reference (primary or secondary) if the current DS1 reference does not provide a valid timing signal. The other DS1 reference is used if one is administered and providing a valid timing signal. Otherwise, the local oscillator of the Tone-Clock circuit pack in the same port network as the DS1 reference is used. The following conditions cause a synchronization switch:

- 1 The current DS1 reference is not inserted (**list configuration board location** shows **no board**).
- 1 The current DS1 reference has a loss of signal error (DS1-BD and UDS1-BD Error Type 1281), a blue alarm error (DS1-BD and UDS1-BD Error Type 1793), a red alarm error (DS1-BD and UDS1-BD Error Type 2049), or a hyperactive Angel error (DS1-BD and UDS1-BD Error Type 1538). A corresponding alarm log entry is not required.
- 1 DS1 and UDS1 circuit packs can be administered with slip detection enabled (the **Slip Detection** field is **y**) on the **add ds1** or **change ds1** administration screens (See *Administering Avaya Aura™ Communication Manager - 555-233-506*). When over half of the DS1 and UDS1 circuit packs administered as slip enabled experience slips, and the primary or secondary synchronization reference is the current synchronization reference, synchronization tries the other administered synchronization reference if the other administered reference does not have the previous two conditions. Use **list measurements ds1-log** to get an historical perspective of DS1 facility operation.

The following conditions cause a change to the other DS1 reference if one exists and the other DS1 reference is more healthy:

- 1 The current DS1 reference has a misframe error (DS1-BD Error Type 3329 to 3345 or UDS1-BD Error Type 3585-3601). A corresponding alarm log entry is not required.
- 1 The current DS1 reference has a slip alarm (DS1-BD and UDS1-BD Error Type 3073 to 3160). A corresponding alarm log entry is required.

If the previous conditions are repaired, synchronization changes back to the primary reference.

### LEDs on Tone-Clock Circuit Packs

The specific flashing pattern of a TN768, TN780, or TN2182 Tone-Clock circuit pack's amber and green LEDs indicates the circuit pack's status. For example, these flashing LED patterns indicate whether the Tone-Clock circuit pack is:

- 1 Deriving timing from an external source
- 1 Providing the timing signal for its PN

The amber and green LED patterns for TN768, TN780, and TN2182 Tone-Clock circuit packs are listed in [Table 246](#):

**Table 246: Tone-Clock Amber/Green LED Flashing Codes**

| <b>Circuit Pack Condition</b>                                                                                                             | <b>Tone-Clock State</b> | <b>Explanation</b>                                                                                                             |
|-------------------------------------------------------------------------------------------------------------------------------------------|-------------------------|--------------------------------------------------------------------------------------------------------------------------------|
| Flashing amber <sup>1</sup><br>2.7 seconds on<br>0.3 seconds off                                                                          | Active                  | An external timing source is being used as a synchronization reference.                                                        |
| Flashing amber<br>0.3 seconds on<br>2.7 seconds off                                                                                       | Active                  | The circuit pack is being used as a synchronization reference.                                                                 |
| Steady amber on                                                                                                                           | Active                  | The circuit pack has been reset, but has not been told which synchronization reference source to use.                          |
| Steady amber off                                                                                                                          | Standby                 | The circuit pack is in standby mode (neither generating tones nor supplying clocks).                                           |
| “Jingle Bells” green and amber<br>0.1 seconds on, 0.2 seconds off,<br>0.1 seconds on, 0.4 seconds off,<br>0.4 seconds on, 0.4 seconds off | Standby                 | The system is running maintenance tests on the standby Tone-Clock circuit pack. (The standby circuit pack is providing tones.) |
| Other green and amber                                                                                                                     | Active                  | The system is running maintenance tests on the active Tone-Clock circuit pack.                                                 |

1. The external synchronization reference being used is a primary reference, or a secondary reference, or an external Stratum-3 clock when the Tone-Clock is in the master PN. The external synchronization reference used in a slave PN is an Expansion Interface circuit pack.

## Error log entries and recommended actions

S8700 | S8710 | S8720 | S8500

Table 247: SYNC Error Log Entries

| Error Type            | Aux Data | Associated Test     | Alarm Level       | On/Off Board | Recommended Action          |
|-----------------------|----------|---------------------|-------------------|--------------|-----------------------------|
| 0 (a)                 | 0        | Any                 | Any               | Any          | <b>test synchronization</b> |
| 1 (b)(i)              |          |                     | WRN<br>MIN (g)    | OFF          |                             |
| 18 (c)                | 0        | <b>disable sync</b> | WRN               | OFF          | <b>enable sync</b>          |
| 257 (d)(i)            |          |                     | WRN<br>MIN (i)(g) | OFF          |                             |
| 513 (e)(i)            |          |                     | WRN<br>MAJ (i)(g) | OFF          |                             |
| 769 (f)               |          |                     | MAJ               | OFF          |                             |
| 1793 (g) <sup>1</sup> | 0–50     |                     | MAJ               | OFF          |                             |
| 2049 (h)              | 0        |                     | WRN               | OFF          |                             |

1. It can take up to 1 hour for these alarms to clear.

Notes:

- a. **Error Type 0:** run the short test sequence first. If every test passes, run the long test sequence. Refer to each test's description, and follow its procedures.
- b. **Error Type 1:** run the short test sequence first. If every test passes, run the long test sequence. Refer to each test's description, and follow its procedures.

This error indicates a problem with the primary DS1 reference. It is cleared when the primary reference is restored. To find the problem's source:

1. Enter **list configuration board location** to check if the primary DS1 Interface circuit pack is inserted in the carrier.
2. Verify that the administered primary reference matches the DS1 reference from the network synchronization plan.

3. Enter `test board location long` to test the primary DS1 Interface circuit pack.  
Check the Error Log for DS1-BD or UDS1-BD errors and see [DS1-BD \(DS1 Interface Circuit Pack\)](#) or [UDS1-BD \(UDS1 Interface Circuit Pack\)](#) to resolve errors associated with the primary DS1 (DS1 or UDS1) interface circuit pack.  
  
If the only errors against DS1-BD or UDS1-BD are slip errors, follow the procedures described in the previous troubleshooting section. If no errors are listed in the Error Log for the primary DS1 Interface circuit pack, continue with the following steps.
  4. Enter `test tone-clock location long` to test the active Tone-Clock circuit pack in the master port network.  
  
Check the Error Log for TDM-CLK errors, and verify that [TDM Bus Clock Circuit Status Inquiry Test \(#148\)](#) passes.  
  
If Test #148 fails with Error Code 2–32, see [TDM-CLK \(TDM Bus Clock\)](#) to resolve the problem. If not, continue with the following.
  5. Use `disable synchronization-switch` and `enable synchronization-switch`. When these two commands are used together, they change the system synchronization reference to the primary DS1 Interface circuit pack.
  6. Check the Error Log and use `status synchronization` to verify that the primary DS1 Interface circuit pack is still the system synchronization reference.  
  
If the primary DS1 Interface circuit pack is not the system synchronization reference, *and* the master port network does not have duplicate Tone-Clock circuit packs, escalate the problem.  
  
Otherwise, continue with the following.
  7. For *duplicated* Tone-Clock circuit packs in the master port network:  
  
Enter `set tone-clock location` to interchange Tone-Clocks in the master port network, and repeat the disable/enable commands described in the previous step.
- c. This error indicates that Synchronization Maintenance was disabled using `disable synchronization-switch`. Use `enable synchronization-switch` to enable Synchronization Maintenance reference switching and to resolve this alarm.
  - d. This error indicates a problem with the secondary DS1 reference. It is cleared when the secondary reference is restored. Refer to note (b) to resolve this error substituting *secondary* for *primary* in the preceding resolution steps.
  - e. This error indicates that the Tone-Clock circuit pack is providing the timing source for the system. The primary and secondary (if administered) are not providing a valid timing signal. Investigate errors 1 and 257 to resolve this error.
  - f. **S8700-series Fiber-PNC**: This error indicates that the external Stratum-3 clock failed to provide the system's timing reference. Refer to Stratum-3 clock's Maintenance document to resolve the defective synchronization reference.

g. This error indicates excessive switching of system synchronization references has occurred. When this error occurs, synchronization is disabled and the Tone-Clock circuit pack (in the master port network) becomes the synchronization reference for the system. Execute the following steps to resolve this error:

1. Check for timing loops, and resolve any loops that exist.
2. Test the active Tone-Clock circuit pack in the master port network using `test tone-clock location long`.

Check the Error Log for TDM-CLK errors, and verify that TDM bus Clock Circuit Status Inquiry test (#148) passes.

If Test #148 fails with Error Code 2–32, see [TDM-CLK \(TDM Bus Clock\)](#) to resolve the problem. If not, continue with the following.

3. For duplicated Tone-Clock circuit packs in the master port network, enter `set tone-clock location` to switch the Tone-Clocks.

For unduplicated Tone-Clock circuit packs in the master port network of a Stratum-4 (not Stratum-3) system, replace the primary and secondary (if assigned) DS1 Interface circuit packs.

4. Investigate any other SYNC or STRAT-3 errors.

---

#### S8700-series Fiber-PNC

h. This error indicates that the Expansion Interface circuit packs are experiencing timing slips. This error increases the bit error rates for data transmission between port networks. The Expansion Interface circuit packs with timing slips have EXP-INTF error 2305.

1. Check the LEDs on the active Tone-Clock circuit packs in the system and verify that the system is properly synchronized.
2. Verify that all the TDM/LAN Bus cables on the backplane are marked WP-91716. Also for a Multi-Carrier Cabinet (MCC), check that the bus terminator type is a ZAHF4 TDM/LAN.

For a Single Carrier Cabinet verify that the bus terminator type is a AHF110 TDM/LAN.

3. Check for timing loops, and resolve any loops that exist.
4. Check the Error Log for any active as well as resolved Expansion Interface circuit pack errors and see [EXP-INTF \(Expansion Interface Circuit Pack\)](#) to resolve any errors found.
5. Duplicated Tone-Clock circuit packs in the slave port networks:
  1. Interchange Tone-Clock circuit packs in the slave port networks where EXP-INTF error 2305 also occurs using `set tone-clock location`. The error count for this error should start to decrement once the problem is solved. If the count does not decrease in 15 minutes, the problem still exists.

- 1 If the problem still exists, switch the Tone-Clock in the slave port network back to the previous configuration, then perform a PNC interchange using **reset pnc interchange**.
- 1 If the problem still exists, switch the PNC back to the previous configuration using **reset pnc interchange**. Switch the Tone-Clock circuit packs in the master port network using **set tone-clock location**.
- 1 If the problem still exists, switch the Tone-Clock circuit packs in the master port network back to the previous configuration using **set tone-clock location**.
- 1 Replace the active Expansion Interface circuit pack in the master port network.
- 1 In a CSS configuration, replace the Switch Node Interface circuit pack connected to the active Expansion Interface circuit pack in the master port network. Use **list fiber-link** to determine the Switch Node Interface circuit pack that is connected to the active Expansion Interface circuit pack in the master port network.
- 1 If the system's synchronization reference is a Tone-Clock circuit pack or a Stratum-3 clock, follow normal escalation procedures.

If the system's primary synchronization reference is a DS1 Interface circuit pack, assign a different DS1 Interface as the primary reference. If the problem persists and slip errors remain, follow the procedures in the troubleshooting section above.

6. For *unduplicated* Tone-Clock circuit packs in a slave port network:

- 1 Enter **set tone-clock location** to switch the Tone-Clock in the master port network.
- 1 If the problem still exists, enter **set tone-clock location** to switch the Tone-Clocks in the master port network back to their previous configuration.  
  
Enter **test tone-clock location long** to test the Tone-Clock in the master and slave port networks.  
  
Check the Error Log for TDM-CLK errors and verify that TDM Bus Clock Circuit Status Inquiry test (#148) passes.  
  
If Test #148 fails with an Error Code 2–32, see [TDM-CLK \(TDM Bus Clock\)](#) to resolve the problem. If not, continue with the following steps.
- 1 If the master and slave Tone-Clock circuit packs do not fail TDM Bus Clock Test #150 (TDM Bus Clock PPM Inquiry test), replace the Expansion Interface circuit packs that have EXP-INTF error 2305.
- 1 If the system synchronization reference is a Tone-Clock circuit pack and the master Tone-Clock circuit pack fails TDM Bus Clock Test #150, follow the steps listed in "TDM-CLK" to replace the master Tone-Clock circuit pack.

- 1 If the system's synchronization reference is a DS1 Interface circuit pack and the master Tone-Clock circuit pack fails TDM Bus Clock test (#150), the primary or secondary (if administered) synchronization references are not providing valid timing signals for the system.  
If the *primary* synchronization reference is providing the system's timing, check the synchronization references administered, and follow the steps outlined in note (b). If the *secondary* reference is providing timing, follow note (d).
- 1 If the slave Tone-Clock circuit pack fails TDM Bus Clock Test #150 but the master Tone-Clock *does not* fail this test, the master Tone-Clock circuit pack must be replaced. Follow the Tone-Clock replacement steps listed in [TDM-CLK \(TDM Bus Clock\)](#).
- 1 Replace the active Expansion Interface circuit pack in the master port network.
- 1 In a CSS configuration, replace the Switch Node Interface circuit pack connected to the active Expansion Interface circuit pack in the master port network. Use `list fiber-link` to determine the Switch Node Interface circuit pack that is connected to the active Expansion Interface circuit pack in the master port network.
- 1 If the problem persists and any slip errors remain, follow the procedures described in the troubleshooting section above.

It may take up to one hour to clear the alarm after the problem has been resolved.

- i. Noise on the DS1 line can cause transient alarms on synchronization. Therefore, when a sync problem occurs on Error Types 1, 257, or 513, a WRN alarm is first raised for 15 to 20 minutes before the alarm is upgraded to a MINOR or MAJOR alarm.

**Table 248: Synchronization Error Log Entries**

| Error Type     | Aux Data | Associated Test           | Alarm Level                 | On/Off Board | Recommended Action                |
|----------------|----------|---------------------------|-----------------------------|--------------|-----------------------------------|
| 0 <sup>1</sup> | 0        | Any                       | Any                         | Any          | <code>test synchronization</code> |
| 1 (a) (g)      | Any      |                           | WRN<br>MIN (j) <sup>2</sup> | OFF          |                                   |
| 18 (b)         | 0        | <code>disable sync</code> | WRN                         | OFF          | <code>enable sync</code>          |
| 257 (c)(g)     | Any      |                           | WRN<br>MIN (j) <sup>2</sup> | OFF          |                                   |
| 513 (d)(g)     | Any      |                           | WRN<br>MAJ (j) <sup>2</sup> | OFF          |                                   |
| 769 (e)        |          |                           | MAJ<br>WRN <sup>3</sup>     | OFF          |                                   |

**Table 248: Synchronization Error Log Entries**

| Error Type            | Aux Data | Associated Test | Alarm Level | On/Off Board | Recommended Action |
|-----------------------|----------|-----------------|-------------|--------------|--------------------|
| 1793 <sup>4</sup>     | 0-50     |                 | MAJ<br>WRN  | OFF          | <b>enable sync</b> |
| 2049 (f) <sup>4</sup> | 0        |                 | WRN         | OFF          |                    |
| 2305 (f) <sup>4</sup> | 0        |                 | WRN         | OFF          |                    |

1. Run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.
2. This Error Type initially raises a Warning alarm. If this Error Type persists and alarms are not downgraded on this MO due to the value of `set options`, then, after a period of time, a Minor or Major alarm is raised.
3. Major alarms on this MO may be downgraded to Warning alarms based on the value used in `set options`.
4. It can take up to one hour for these SYNC alarms to clear.

Notes:

- a. **Error Type 1:** problem with the primary DS1 reference. It is cleared when the primary reference is restored. The following steps should give an indication of the source of the problem:
  1. Check if the primary DS1 interface circuit pack is inserted in the carrier using `list configuration board location`.
  2. Check the connection of the cable supplying the external timing source to the primary DS1 interface circuit pack.
  3. Test the primary DS1 interface circuit pack using `test board location long`. Check the Error Log for DS1-BD errors and refer to the DS1-BD (DS1 Interface Circuit Pack) Maintenance documentation to resolve any errors associated with the primary DS1 interface circuit pack. If no errors are listed in the Error Log for the primary DS1 interface circuit pack, continue with the following steps.
  4. Test the active Tone-Clock circuit pack in the master port network using `test tone/clock location long`. Check the Error Log for TDM-CLK errors and verify that TDM Bus Clock Test #148 passes successfully. If Test #148 fails with an Error Code 2 through 32, refer to [TDM-CLK \(TDM Bus Clock\)](#) to resolve the problem. If not, continue with the following steps.
  5. Execute `disable synchronization-switch` and the `enable synchronization-switch`. These two commands (when executed together) switch the system synchronization reference to the primary DS1 interface circuit pack. Check the Error Log and execute the `status synchronization` command to verify that the primary DS1 interface circuit pack is still the system synchronization reference. If the primary DS1 interface circuit pack is not the system synchronization reference, continue with the following step.

- b. **Error Type 18:** Synchronization Maintenance has been disabled using `disable synchronization-switch`. Execute `enable synchronization-switch` to enable Synchronization Maintenance reference switching and to resolve this alarm.
- c. **Error Type 257:** problem with the secondary DS1 reference. It is cleared when the secondary reference is restored. Refer to note (a) to resolve this error substituting *secondary* for *primary* in the preceding resolution steps.
- d. **Error Type 513:** the Tone-Clock circuit pack is providing the timing source for the system. The primary and secondary (if administered) are not providing a valid timing signal. Investigate errors 1 and 257 to resolve this error.
- e. **Error Type 769:** excessive switching of system synchronization references has occurred. When this error occurs, synchronization is disabled and the Tone-Clock circuit pack (in the master port network) becomes the synchronization reference for the system. Execute the following steps to resolve this error:
  - 1. Check for timing loops and resolve any loops that exist.
  - 2. Test the active Tone-Clock circuit pack in the master port network using `test tone/clock location long`. Check the Error Log for TDM-CLK errors and verify that TDM Bus Clock Test #148 passes successfully. If Test #148 fails with an Error Code 2 through 32, refer to the TDM-CLK (TDM Bus Clock) Maintenance documentation to resolve the problem. If not, continue with the following steps.
  - 3. Replace the primary and secondary (if administered) DS1 Interface circuit packs.
  - 4. Check for an error logged against the primary or secondary DS1 board. If there is an error, follow the DS1 section to resolve the errors. If there is not, enter `enable sync`, and wait for two to five minutes for the primary sync source to come on-line.
- f. **Error Type 2049:** the slave Tone-Clock circuit pack is experiencing loss of signal. Refer to note (i) for error resolution steps.

The following steps should be executed to resolve error **2049** and **2305**:

- 1. Check for timing loops, and resolve any loops that exist.
- 2. **Error 2049:**
  - 1. Test the Tone-Clock circuit packs in the master and slave port networks using `test tone/clock location long`. Check the Error Log for TDM-CLK errors and verify that TDM Bus Clock Test #148 passes successfully. If Test #148 fails with an Error Code 2 through 32, refer to [TDM-CLK \(TDM Bus Clock\)](#) to resolve the problem. If not, continue with the following steps.
  - 1. If the system synchronization reference is a Tone-Clock circuit pack and the master Tone-Clock circuit pack fails TDM Bus Clock Test #150, follow the steps listed in [TDM-CLK \(TDM Bus Clock\)](#) to replace the master Tone-Clock circuit pack.

- 1 If the system synchronization reference is a DS1 interface circuit pack and the master Tone-Clock circuit pack fails TDM Bus Clock Test #150, the primary or secondary (if administered) synchronization references are not providing valid timing signals for the system. Check the system synchronization references administered, and follow the steps outlined in note (a) if the primary synchronization reference is providing timing for the system or note (c) if the secondary synchronization reference is providing timing for the system.
- 1 If the slave Tone-Clock circuit pack fails the TDM Bus Clock Test #150 but the master Tone-Clock *does not* fail this test, the master Tone-Clock circuit pack must be replaced.

If SLIP errors remain follow SLIP ANALYSIS.

### 3. Error 2305:

- 1 If the problem persists, replace the Tone-Clock circuit pack in the slave port network. Follow the steps listed in [TDM-CLK \(TDM Bus Clock\)](#) to replace the Tone-Clock circuit pack.
- g. Noise on the DS1 line can cause transient alarms on synchronization. Therefore, when a synchronization problem occurs causing Error Types 1, 257, or 513, a WRN alarm is first raised for 15 to 20 minutes before the alarm is upgraded to a MAJOR or MINOR alarm.

## Demand test descriptions and error codes

**S8700-series Fiber-PNC:** If Stratum 3 is administered using `change synchronization`, the [Stratum-3 Clock Alarm Query \(#649\)](#) also executes when `test synchronization` is run.

| Order of Investigation                             | Short Test Sequence | Long Test Sequence | D/ND            |
|----------------------------------------------------|---------------------|--------------------|-----------------|
| <a href="#">Synchronization Update Test (#417)</a> | X                   | X                  | Non-Destructive |

## SYS-LINK (System Links)

| MO Name in Log | Alarm Level | Initial Command to Run              | Full Name of MO |
|----------------|-------------|-------------------------------------|-----------------|
| SYS-LINK       | MIN<br>WRN  | <code>test sys-link location</code> | SYSTEM LINKS    |

System links are packet links that originate at the Packet Interface board and traverse various hardware components to specific endpoints. The hardware components involved on the forward and reverse routes can be different, depending upon the configuration and switch administration. Various types of links are defined by their endpoints:

|      |                                                                                                                                                                                                               |
|------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| EAL  | Expansion Archangel Link terminating at an Expansion Interface board. This link carries CCMS messages.                                                                                                        |
| INL  | Indirect Neighbor Link terminating at a Switch Node Interface board.                                                                                                                                          |
| PACL | PNC ATM Control Link terminating at a PNC ATM-EI board. This link carries ATM signaling commands to the remote TN2238 (ATM-EI) boards.                                                                        |
| PRI  | ISDN-PRI D-Channel Link terminating at a Universal DS1 board                                                                                                                                                  |
| RSCL | Remote Socket Control Link terminating at a C-LAN board                                                                                                                                                       |
| RSL  | Remote Socket Link terminating at a C-LAN board                                                                                                                                                               |
| BFDL | Bearer Fault Detection Link terminating at an Expansion Interface board. This link provides inter-port-network bearer fault detection for port-networks that do not use an EAL terminating at the EI board.   |
| MBL  | Maintenance Board Link terminating at an IPSI board that provides Environmental maintenance for a G650 rack mounted cabinet. This replaces the Expansion Port-Network (EPN) maintenance board serial channel. |
| TACL | ATM control link terminating at an ATM-TRK board. This link carries ATM signaling commands to the ATM-TRK) board.                                                                                             |

---

## Recording System Link Events

The system records every error encountered on the system links. Most of these events are not extraordinary unless they occur very often. The events are logged as they occur, leaving a "trail" to help analyze abnormal behavior exhibited by the endpoints attached to the links or the links themselves.

When a link goes down, an alarm is raised immediately. For EAL, INL, BFDL, and PACL link types, a MINOR alarm is raised. For every other link type, a WRN alarm is raised. Other alarming conditions that do not cause the link to go down get a WRN alarm, regardless of the link type.

---

## Identifying a System Link

In order to trace problems associated with a system link, it is necessary to find its location. Use the following methods to find the location of the system link.

### Display Errors/Alarms

The output of `display errors` or `display alarms` shows the location of the system link for entries with a Maintenance Name of SYS-LINK. You can restrict the scope of the output of these commands by specifying `sys-link` in the **Category** field on the input screen. The link type and channel number, if any, are listed under the **Alt Name** field of the report.

### List sys-link

The `list sys-link` command lists every system link (location, link type, and dcli number) present in the system.

---

## Common Procedure for Repairing Link Problems

The state of a system link is dependent on the state of the various hardware components that it travels over. To resolve any problems associated with a system link, use the following procedure.

The switch maintains a list of hardware components over which the link travels, called the hardware path. There are two hardware paths: the current hardware path and the faulted hardware path for each of the system links. The current hardware path is present only for those links that are currently up. When a link is down, the current hardware path is empty. The faulted hardware path is always present once the link has gone down, and is not cleared when the link subsequently recovers. The faulted path preserves the path that the link traversed when it last went down. The time at which the faulted path was last recorded is preserved and is accessible through `status sys-link location` and `list sys-link`. Therefore, the focus of attention for problems which do not involve a link that is down is the current hardware path. If the link is down, faulted hardware path is the focus of attention.

The `status sys-link location` command shows the state of both the hardware paths (current and faulted) along with the state of each of the components in the hardware path. When analyzing any system link problem:

1. Look for alarms on the components listed under desired hardware path.
2. If any alarms are present, then follow the maintenance procedures for the alarmed components to clear those alarms first.

**Note:**

For systems using ATM-EI (TN2305/6 circuit packs) and where link alarms are present, see [ATM-EI \(Expansion Interface Circuit Pack\)](#).

3. When every component is alarm free, wait for 3 minutes to allow the links to recover.
4. Test the system link (`test sys-link location long clear`), and notice any tests that fail.
5. If there are any failures, fix the problems indicated by the tests and repeat the procedure.

---

## Error log entries and recommended actions

**Table 249: SYS-LINK Error Log Entries**

| Error Type               | Aux Data | Associated Test           | Alarm Level | On/Off Board | Recommended Action                       |
|--------------------------|----------|---------------------------|-------------|--------------|------------------------------------------|
| 13 <a href="#">(a)</a>   |          | System Link Status (#985) | MIN WRN     | OFF          |                                          |
| 257 <a href="#">(b)</a>  |          |                           | WRN         | OFF          | <code>test sys-link location 1 c1</code> |
| 513 <a href="#">(c)</a>  |          |                           | WRN         | OFF          | <code>test sys-link location 1 c1</code> |
| 772 <a href="#">(d)</a>  |          |                           | WRN         | OFF          | <code>test sys-link location 1 c1</code> |
| 1025 <a href="#">(e)</a> |          |                           | WRN         | OFF          | <code>test sys-link location 1 c1</code> |
| 1281 <a href="#">(f)</a> |          |                           | WRN         | OFF          | <code>test sys-link location 1 c1</code> |
| 1537 <a href="#">(g)</a> |          |                           | WRN         | OFF          | <code>test sys-link location 1 c1</code> |
| 1793 <a href="#">(h)</a> |          |                           | WRN         | OFF          | <code>test sys-link location 1 c1</code> |
| 2049 <a href="#">(i)</a> |          |                           | WRN         | OFF          | <code>test sys-link location 1 c1</code> |

Notes:

- a. **Error Type 13:** the link went down. The link may have gone down or never come up. Enter `status sys-link location` and check the value of the **Faulted Path** field. If the value is **default**, then the link never came up. If the value is **present**, then the link came up and then went down.
  1. Follow the information in [Common Procedure for Repairing Link Problems](#).
  2. Wait for 3–5 minutes before checking the link state.
  3. Repeat the procedure until there are no problems.

- b. **Error Type 257:** the link has experienced uplink flow control, and the endpoint may be hyperactive. The system link is alarmed if 4 or more errors of this type are detected within 10 minutes.
  - 1. Follow the information in [Common Procedure for Repairing Link Problems](#).
  - 2. Clear errors and wait for 10 minutes.
- c. **Error Type 513:** the link has experienced downlink flow control, meaning that some information packets from the packet interface board have been lost. The link is reset on first occurrence and Error 1025 is also logged. The system link is alarmed if 2 or more errors of this type are detected within 10 minutes.
  - 1. Follow the information in [Common Procedure for Repairing Link Problems](#).
  - 2. Clear errors and wait for 10 minutes.
- d. **Error Type 772:** the link experienced a temporary disconnect due to excessive resets or state transitions, meaning that the link is taken down and then brought up again. The system link is alarmed if 2 or more errors of this type are detected within 10 minutes.
  - 1. Follow the information in [Common Procedure for Repairing Link Problems](#).
  - 2. Clear errors and wait for 10 minutes.
- e. **Error Type 1025:** the link has been reset, meaning that information packets queued at the time of reset are lost. The system link is alarmed if 20 or more errors of this type are detected within 10 minutes.
  - 1. Follow the information in [Common Procedure for Repairing Link Problems](#).
  - 2. Clear errors and wait for 10 minutes.
- f. **Error Type 1281:** the link has experienced slow transmit rate because the remote endpoint is busy. The effect of this error is that the endpoint location may experience slower throughput rate and/or noisy transmission. The system link is alarmed if 4 or more errors of this type are detected within 10 minutes.
  - 1. Ensure that the remote endpoint is functioning properly.
  - 2. Follow the information in [Common Procedure for Repairing Link Problems](#).
  - 3. Clear errors and wait for 10 minutes.
- g. **Error Type 1537:** the link has experienced slow transmit rate due to excessive retransmission. Possible causes may be that the switch is overrunning the endpoint, or that the endpoint is not operating properly. The effect is that the endpoint location may experience slower throughput rate. The system link is alarmed if 4 or more errors of this type are detected within 10 minutes.
  - 1. Follow the information in [Common Procedure for Repairing Link Problems](#).
  - 2. Clear errors and wait for 10 minutes.

- h. **Error Type 1793:** This error indicates that the link has experienced slow transmit rate due to unknown causes, meaning that the endpoint location may experience slower throughput rate and the Packet Interface may experience backup or congestion. The system link is alarmed if 4 or more errors of this type are detected within 10 minutes.
  1. Follow the information in [Common Procedure for Repairing Link Problems](#).
  2. Clear errors and wait for 10 minutes.
- i. **Error Type 2049:** the link has transmitted an excess amount of packets. The transmit buffers of this link have been purged. The system link is alarmed if 4 or more errors of this type are detected within 10 min.
  1. Follow the [Common Procedure for Repairing Link Problems](#).
  2. Clear errors and wait for 10 min.

## Demand test descriptions and error codes

Testing for system links is different from the standard test procedures for MOs. In addition to testing the system link MO, the user can test every component in the path of the system link. There are two paths preserved for the link. The current path, if present, represents the path traversed by the link currently. This path is absent when the link is down. The other path, the faulted path, is present if the link has ever gone down or never come up. If the link came up and went down, then the **Faulted Path** is marked **present**. If the link never came up, the **Faulted Path** is marked **default**. In either case, it represents the path on which the link was attempted or established unsuccessfully.

Test command for the system links, `test sys-link location`, can be specified with current or faulted as an optional argument if the user wishes to test every component in the specified path. The tests executed are the same if the user tests each component manually. In the event that the user does not specify any path, then only the tests specified for the system links are executed.

| Order of Investigation                         | Short Test Sequence | Long Test Sequence | D/ND            |
|------------------------------------------------|---------------------|--------------------|-----------------|
| <a href="#">System Link Status Test (#985)</a> | X                   | X                  | Non-Destructive |

## SYS-PRNT (System Printer)

| MO Name in Log | Alarm Level | Initial Command to Run       | Full Name of MO |
|----------------|-------------|------------------------------|-----------------|
| SYS-PRNT       | MIN         | <code>test sp-link 1</code>  | System Printer  |
|                | WRN         | <code>release sp-link</code> |                 |

The Report Scheduler feature provides the capability to schedule printing of output screen selected administration commands on an asynchronous System Printer (SYS-PRNT) or a Personal Computer (PC). The System Printer device connects to the system via a data module (PDM, MPDM, DTDM) connected to a port on a TN754 Digital Line circuit pack which is administered as a data extension. A System Printer device can also be connected through an ADU to a port on TN726B Data Line circuit pack. The System Printer link to the processor is via a C-LAN board. For information about C-LAN connectivity, see [CLAN-BD \(Control LAN Circuit Pack\)](#).

System Printer Link Maintenance provides a strategy for maintaining the link between the system and an external SYS-PRNT output device. The strategy includes a set of tests for detection of errors during normal operation, troubleshooting actions, and alarms for serious problems. System Printer Link Maintenance uses a try-and-wait mechanism for maintaining the SYS-PRNT link. A minor alarm is raised when the link set-up fails. A warning alarm is raised when the server has been busied out. Up to two link retry attempts are made. After the second attempt, set-up attempts are only made by the application software. (The 15-minute timer fires and jobs are printed unless an immediate job was entered.) After two unsuccessful attempts to establish the link, a MINOR alarm is raised. If the System Printer Link is torn down due to an error, System Printer Link Maintenance will raise a MINOR alarm but will not attempt to bring up the System Printer Link.

System Printer Link Maintenance does not cover the elements comprising the SYS-PRNT physical link: the external SYS-PRNT output device, the Data Module (PDM/MPDM/DTDM) and TN754 Digital Line, or the ADU and TN726B Data Line. If System Printer Link Maintenance cannot restore the System Printer Link, the maintenance tests of these individual components of the System Printer Link must be executed to diagnose faults.

### Procedures for Restoring the System Printer Link

1. Use `status sp-link` and verify that the **Maintenance Busy** field is **n**, which shows that the System Printer Link is not busied out for maintenance. If the System Printer Link has been busied out, use `release sp-link`. If the link is down, proceed to Step 2.
2. Use `display system-parameters features` to determine the location of the System Printer Link.

Use `status data-module extension` and verify that the data extension is in-service/idle. If the data extension is *not* available, refer to the `Port` field. Look for errors and/or alarms on the circuit pack with which this extension is associated. Follow repair instructions for the appropriate MO. Continue with Step 3.

3. Verify the availability of the external SYS-PRNT output device. Make sure that the output device is *on-line* and ready-for-service. Check the physical connectivity between the Data Module and the SYS-PRNT output device.
4. Verify that there is at least one C-LAN port available. The System Printer Link cannot be established without an available C-LAN port. For more information about C-LAN ports, see [CLAN-BD \(Control LAN Circuit Pack\)](#).
5. If the problem is not found in the previous steps, check the C-LAN port for problems. For a description of C-LAN boards and connectivity, see [CLAN-BD \(Control LAN Circuit Pack\)](#).

When restoring the System Printer link, execute tests on different MOs that comprise the System Printer link. It is recommended that you busyout the System Printer link before trying to restore the link. When the System Printer Link is busyout, every System Printer Link maintenance action is deactivated, and interference with tests of other MOs is prevented.

---

## Error log entries and recommended actions

**Table 250: SYS-PRNT Error Log Entries**

| Error Type | Aux Data | Associated Test              | Alarm Level          | On/Off Board | Recommended Action           |
|------------|----------|------------------------------|----------------------|--------------|------------------------------|
| 0          | 0        | Any                          | Any                  | Any          | <code>test sp-link</code>    |
| 18 (a)     | 0        | <code>busyout sp-link</code> | WRN                  | OFF          | <code>release sp-link</code> |
| 257 (b)    | 1, 3-6   | Link Retry test (#215)       | MIN <sup>1</sup> WRN | OFF          | <code>test sp-link 1</code>  |
| 513 (c)    | 0        |                              | MIN                  | OFF          | <code>test sp-link</code>    |

1. Minor alarms can be downgraded to Warning alarms based on the value used in **set options**.

### Notes:

- a. **Error Type 18:** the System Printer Link has been busyout.
- b. **Error Type 257:** a failure was encountered while attempting to set up the System Printer Link. This attempt could have been initiated by either Report Scheduler software or by link maintenance during automatic link retry or as a result of a [Link Retry Test \(#215\)](#) request.

The Aux Data field indicates the following:

**Table 251: Aux Data, Error Type 257**

| Aux Data | Description                                                                                                                                                      |
|----------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1        | No C-LAN port available. See <a href="#">CLAN-BD (Control LAN Circuit Pack)</a> for explanation.                                                                 |
| 3, 4     | Time-out during setup attempt. Most likely due to problem with physical link or printer status.                                                                  |
| 5        | Internal system error. Most likely temporary/sporadic failure.                                                                                                   |
| 2, 6     | The data module the printer is trying to use is busy with another call. Use <code>status data module</code> to determine when the port is available for testing. |

See [Procedures for Restoring the System Printer Link](#) for recommended maintenance strategy.

c. **Error Type 513:** the SYS-PRNT was interrupted for one of the following reasons:

- 1 The cable to the SYS-PRNT output device is disconnected
- 1 The SYS-PRNT output device is powered off
- 1 The data extension to which the SYS-PRNT output device connects has been busied out
- 1 Internal software error

Check the connectivity of the wires and cables among the wall jacket, data module, and SYS-PRNT output device. Follow the instructions in [Procedures for Restoring the System Printer Link](#).

---

## Demand test descriptions and error codes

Investigate tests in the order presented. By clearing errors associated with the first test, errors generated from other tests may also be cleared. Click on the link to see the full description of the test, error codes, and recommended actions.

| Order of Investigation                     | Short Test Sequence | Long Sequence | D/ND            |
|--------------------------------------------|---------------------|---------------|-----------------|
| <a href="#">Link Tear Down Test (#213)</a> |                     | X             | Destructive     |
| <a href="#">Link Retry Test (#215)</a>     | X                   | X             | Non-Destructive |

## SYSTEM (System)

| MO Name | Alarm Level | Initial Command to Run <sup>1</sup> | Full Name of MO |
|---------|-------------|-------------------------------------|-----------------|
| SYSTEM  | None        | None                                | System          |

1. SYSTEM has no associated alarms and thus appears only in the Error Log. There are no tests that run on SYSTEM.

The SYSTEM maintenance object logs information about system resets, including interchanges. When software encounters a problem with hardware, or with its own processes, and requests a restart to clear the problem, an error is logged under SYSTEM. For example, if there is a loss of clocking in a system with duplicated servers, the system switches to the other clock and then executes a level-2 system reset to recover from hardware problems caused by the loss of clock. Errors logged under SYSTEM can help to determine the cause of a reset. For more information about interchanges, see [Troubleshooting duplicated servers](#) in *Maintenance Procedures (03-300432)*.

The `display initcauses` screen also contains information about the reset.

---

## Error log entries and recommended actions

The Aux Data field may be 0 or the return code from a bad software call, and the following examples in no way exhaust the possibilities. Often, two errors are logged at the same time for each problem.

**Table 252: SYSTEM Error Log Entries 1 of 2**

| Error Type                | Aux Data | Associated Test | Alarm Level | On/Off Board | Recommended Action |
|---------------------------|----------|-----------------|-------------|--------------|--------------------|
| 0 ( <a href="#">a</a> )   | 0        | Any             | Any         | Any          |                    |
| 8 ( <a href="#">b</a> )   | 0        |                 |             |              |                    |
| 9 ( <a href="#">c</a> )   | Any      |                 |             |              |                    |
| 10 ( <a href="#">d</a> )  | Any      |                 |             |              |                    |
| 21 ( <a href="#">e</a> )  |          |                 |             |              |                    |
| 355 ( <a href="#">f</a> ) | Any      |                 |             |              |                    |
| 356 ( <a href="#">g</a> ) | Any      |                 |             |              |                    |
| 601 ( <a href="#">h</a> ) |          |                 |             |              |                    |
|                           |          |                 |             |              | <b>1 of 2</b>      |

**Table 252: SYSTEM Error Log Entries 2 of 2**

| <b>Error Type</b> | <b>Aux Data</b> | <b>Associated Test</b> | <b>Alarm Level</b> | <b>On/Off Board</b> | <b>Recommended Action</b> |
|-------------------|-----------------|------------------------|--------------------|---------------------|---------------------------|
| 602 (i)           |                 |                        |                    |                     |                           |
| 603 (j)           |                 |                        |                    |                     |                           |
|                   |                 |                        |                    |                     | <b>2 of 2</b>             |

Notes:

- a. **Error Type 0:** run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.
- b. **Error Type 8:** a System Restart Level 3 was requested.
- c. **Error Type 9:** a System Restart Level 2 was requested. This can happen due to a loss of tones (due to a faulty Tone-Clock circuit pack).
- d. **Error Type 10:** a System Restart Level 1 was requested.
- e. **Error Type 21:** a process trapped.
- f. **Error Type 355:** a Restart Level 2 occurred due to a power loss.
- g. **Error Type 356:** a Restart Level 2 occurred due to a tone clock loss.
- h. **Error Type 601:** an error occurred during initialization.
- i. **Error Type 602:** an error occurred while loading translations and the system requested a Restart Level 3.
- j. **Error Type 603:** a process was reset.

## S8400-BD (S8400 Server)

### S8400

| MO Name in Log | Alarm Level | Initial Command to Run | Full Name of MO |
|----------------|-------------|------------------------|-----------------|
| S8400-BD       | WRN         | None                   | S8400 Server    |

The S8400 Server is a Linux-based server that occupies a single slot in a standard TN carrier. The S8400 Server provides Communication Manager processing functionality in stand alone, single port network (PN), telephony systems requiring up to 500 stations.

The S8400 Server is comprised of the:

- 1 TN8400AP Server circuit pack
- 1 TN8412AP S8400 IP Interface (SIPI) circuit pack

---

## Error log entries and recommended actions

**Table 253: S8400-BD Error Log Entries**

| Error Type | Aux Data                             | Associated Test        | Alarm Level | On/Off Board | Recommended Action         |
|------------|--------------------------------------|------------------------|-------------|--------------|----------------------------|
| 1 (a)      |                                      | Serial Link Test #1647 | WRN         | ON           | <i>test board location</i> |
| 513 (b)    | 4352<br>4353<br>4355<br>4356<br>4358 |                        | WRN         | ON           |                            |
| 1537 (c)   |                                      |                        | WRN         | ON           |                            |
| 3841 (d)   |                                      |                        |             |              |                            |

Notes:

- a. **Error Type 1:** Serial Link Test failure. Either the main server is down or the network is down.
- b. **Error Type 513:** transient hardware device problems on the board. They include an external RAM failure, internal RAM failure, ROM checksum failure, message corruption, and program logic inconsistency. If the board detects only one of these hardware problems it may be alarmed. The error will disappear when none of these faults are detected for 10 minutes. There are no associated tests for these inline errors; if they continue to happen, the circuit pack should be replaced.

- c. **Error Type 1537:** Serial Link Hyperactivity. The switch removed the hyperactive circuit pack. Attempt to clear the alarm with the **busyout/reset/release board location** commands. If the error occurs within 15 minutes, replace the circuit pack.
- d. **Error Type 3841:** Inconsistent downlink message. This error is not service-affecting. No action is required.

---

## Demanded tests descriptions and error codes

| Order of Investigation                     | Short Test Sequence | Long Test Sequence | D/ND            |
|--------------------------------------------|---------------------|--------------------|-----------------|
| <a href="#">System Link Status (#1647)</a> | X                   | X                  | Non-Destructive |

## TBRI-BD (ISDN Trunk-Side BRI Circuit Pack)

| MO Name in Log | Alarm Level | Initial Command to Run                | Full Name of MO                  |
|----------------|-------------|---------------------------------------|----------------------------------|
| TBRI-BD        | MIN         | <code>test board location long</code> | ISDN Trunk-side BRI Circuit Pack |

The TN2185 ISDN trunk-side BRI circuit pack contains eight, 4-wire ports that interface to the network at the ISDN S/T reference point over two 64 Kb/s channels (B1 and B2) and over a 16Kb/s signaling (D) channel.

The B1 and B2 channels can be simultaneously circuit-switched or individually packet-switched. Only one channel per trunk can be packet-switched due to PPE (Packet Processing Element) limitations. The D-channel is either circuit-switched or packet-switched. Packet switching uses the PPE to combine all D-channels into a single physical channel, which is then routed via the concentration highway to the NCE (Network Control Element) and then to the TDM bus. The circuit-switched connections have a Mu-law or A-law option for voice and operate as 64-kbps clear data channels. The packet-switched channels support the LAPD protocol and conform with the CCITT Q.920 Recommendations for D-channel signaling.

---

## Error log entries and recommended actions

Table 254: TBRI-BD Error Log Entries 1 of 2

| Error Type | Aux Data      | Associated Test                       | Alarm Level | On/Off Board | Recommended Action                    |
|------------|---------------|---------------------------------------|-------------|--------------|---------------------------------------|
| 0 (a)      | 0             | Any                                   | Any         | Any          | <code>test board location</code>      |

**Table 254: TBRI-BD Error Log Entries 2 of 2**

| Error Type | Aux Data    | Associated Test | Alarm Level | On/Off Board | Recommended Action |
|------------|-------------|-----------------|-------------|--------------|--------------------|
| 1794 (j)   | 46094       |                 | MIN         | ON           |                    |
| 1795 (j)   | 46085       |                 | MIN         | ON           |                    |
| 2305 (k)   | 46104       |                 | None        | ON           |                    |
| 2306 (k)   | 46081       |                 | None        | ON           |                    |
| 3330 (k)   | 46083       |                 | MIN         | OFF          |                    |
| 3586 (l)   |             |                 | MIN         | OFF          |                    |
| 3841 (m)   | 4096 - 4101 |                 |             |              |                    |
| 3842 (n)   | 46095       |                 |             |              |                    |
| 3843 (o)   | 46097       |                 |             |              |                    |
|            |             |                 |             |              | <b>2 of 2</b>      |

Notes:

- a. **Error Type 0:** run the short test sequence first. If every test passes, run the long test sequence. Refer to each appropriate test's description, and follow its recommended procedures.
- b. **Error Type 1:** the circuit pack stopped functioning or was physically removed from the system. This alarm logs approximately 11 minutes after removing the circuit pack and/or the [SAKI Sanity Test \(#53\)](#) fails.  
 If the circuit pack is not in the system, insert a circuit pack in the same slot as the error indicates. See note (h) for additional information.
- c. **Error Type 257:** transient communication problems between the switch and this circuit pack. Execute *test board location* and refer to the repair procedures for the [Control Channel Looparound Test \(#52\)](#).
- d. **Error Type 513:** on-board hardware failure. Aux Data values correspond to the following detected errors:  
 Aux Data 4352: External RAM error  
 Aux Data 4353: Internal RAM error  
 Aux Data 4355: ROM Checksum error  
 Aux Data 4357: Instruction set error  
 Use *busyout board location* and *reset board location* to reset the circuit pack. When reset, the circuit pack executes a set of tests to detect the presence of any of the faults listed above. Detection of one of these errors during initialization causes the circuit pack to lock-up and appear insane to the system. See the repair procedure in Note (b).

- e. **Error Type 769:** the circuit pack detects a program logic error. While no action is required, this error can lead to other errors against this circuit pack.
- f. **Error Type 1025:** the circuit pack cot update and read back NPE/NCE memory. This error can be ignored, but may lead to other errors against this circuit pack.
- g. **Error Type 1291:** the TN2185 board notifies maintenance software that it has detected a parity while accessing its dynamic RAM (memory that stores the board's translation information and downloadable application firmware). Maintenance software resets the circuit pack.
- h. **Error Type 1294:** unable to write LAN Translation RAM Error (internal memory access error). Translation RAM locations for the call connection attempt are not available, and one or more RAM locations are bad due to a translation RAM read-back error. Reset the circuit pack with `busyout board location` and `reset board location`. If the [Circuit Pack Restart Test \(#594\)](#) passes, then the on-board circuitry is healthy. Retire the alarm with `test board location long clear`. If the Circuit Pack Restart test (#594) fails, replace the circuit pack.
- i. **Error Type 1537:** frame overrun at Packet bus interface. This condition is due to an on-board fault or by faulty data received on one of the circuit pack's external ports. If any of the ports on this circuit pack is alarmed, refer to the repair procedures for those MOs. If this error persists, maintenance software removes the board from service. Replace the circuit pack.
- j. **Error Type 1792 - 1795:** the circuit pack is having problems transmitting/receiving data to/ from the Packet bus.

|      |                                                                                                                                                                                                                                                                                                                         |
|------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1793 | Parity errors are detected when transmitting data to the Packet bus.                                                                                                                                                                                                                                                    |
| 1794 | Packet bus transmit buffers overflow.                                                                                                                                                                                                                                                                                   |
| 1795 | Circuit pack cot find end of frame when transmitting to Packet bus. Clear the alarm with <code>busyout board location</code> , <code>reset board location</code> , <code>test board location long clear</code> , <code>release board location</code> . If the error recurs within 10 minutes, replace the circuit pack. |

- k. **Error Type 2305, 3330:** critical failure in the Circuit Pack's Packet bus interface. Possible causes include either a Packet Bus fault or an on-board fault. If the Packet Bus is alarmed, see [isolating and repairing packet-bus faults](#) in *Maintenance Procedures (03-300432)*. The number of ISDN circuit packs displaying this error increases the probability of errors due to Packet bus problems.
  1. If there are no Packet Bus alarms, reset the circuit pack with `busyout board location`, `reset board location`, and `release board location`.
  2. If the [Circuit Pack Restart Test \(#594\)](#) passes, the on-board circuitry is healthy. Retire the alarm with `test board location long clear`.

3. If the Circuit Pack Restart test (#594) fails, replace the circuit pack.

**Error Type 2306:** This is an error in a received frame from the Packet bus, most likely caused by a packet bus problem, but may be due to a circuit pack fault. An invalid Link Access Procedure Data (LAPD) frame error occurs if the frame contains a bad Cyclical Redundancy Check (CRC). If bus parity errors occur, run the [LANBIC Receive Parity Error Counter Test \(#595\)](#) to determine whether the condition has cleared. Determine whether the problem is isolated to this circuit pack or is caused by Packet bus faults.

l. **Error Type 3586:** the server's software detects an excessive number of uplink messages from the TN2185 board within a certain time period. To prevent the faulty board from flooding the switch with data, the switch software takes the board out of service and alarms it. The switch software also tells the Archangel to ignore uplink messages from the board.

When the board is alarmed due to this error, the switch software periodically puts the board back in service and tells the Archangel to process uplink messages from the board. If the problem still exists, the software takes the circuit pack out of service again. If the circuit pack does not exhibit the problem for a certain time period, then maintenance software resolves the alarm and the circuit pack is left in service.

m. **Error Type 3841:** the circuit pack received an inconsistent down-link message (a bad header, port number, data, sub-qualifier, or logical link) over the Control Channel.

n. **Error Type 3842:** the board is receiving data from the bus faster than it can distribute the data to its endpoints, causing the FIFO RAM buffer to overflow. This error can occur occasionally due to the statistical sizing of the buffers. If it occurs frequently, it may indicate a LAPD parameter mismatch. LAPD should recover from this problem, but it may degrade the performance of the LAN bus.

When this error is reported, maintenance reads and clears the board counter and logs the problem in the maintenance error log.

o. **Error Type 3843:** bad translation RAM detected, but the call continues by using another translation location. The circuit pack reports this error when it cot update NPE/NCE memory and read it back. This error is not service-affecting and can be ignored, but can lead to other types of errors against this circuit pack.

---

## Demand test descriptions and error codes

Investigate tests in the order presented. By clearing errors associated with the first test, errors generated from other tests may also be cleared. Click on the link to see the full description of the test, error codes, and recommended actions.

| Order of Investigation                                          | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|-----------------------------------------------------------------|---------------------|--------------------|-------------------|
| <a href="#">Control Channel Looparound Test (#52)</a>           | X                   | X                  | ND                |
| <a href="#">NPE Audit Test (#50)</a>                            |                     | X                  | ND                |
| <a href="#">LANBIC Receive Parity Error Counter Test (#595)</a> |                     | X                  | ND                |

1. Destructive; ND = Nondestructive

## TBRI-PT (ISDN Trunk-Side BRI Port)

| MO Name in Log | Alarm Level | Initial Command to Run            | Full Name of MO          |
|----------------|-------------|-----------------------------------|--------------------------|
| TBRI-PT        | MAJ<br>MIN  | <code>test port location 1</code> | ISDN Trunk-side BRI port |
|                | WRN         | <code>test port location</code>   |                          |

The TBRI-PT maintenance object is a port on both the TN2185 Trunk-Side BRI circuit pack and the MM720 BRI Media Module. The term *circuit pack* in the following description refers to both the circuit pack and the media module.

The *location* on the TN2185 Trunk-Side BRI circuit pack is the UUCSSpp designation.

The *location* on the MM720 BRI Media Module is designated by GGGVSP. Consult local records for the location and designation of the equipment rack where the Media Gateway is mounted.

The TN2185 circuit pack contains eight, 4-wire ports that interface to the network at the ISDN S/T reference point over two 64-kbps channels (B1 and B2) and over a 16-kbps signaling (D) channel. The B1 and B2 channels can be simultaneously circuit-switched, or individually packet-switched. Only one channel per trunk can be packet-switched due to PPE (Packet Processing Element) limitations. The D-channel is either circuit- or packet-switched. Packet switching uses the PPE to combine all D-channels into a single physical channel, which is then routed via the concentration highway to the NCE (Network Control Element) and then to the TDM bus. The circuit-switched connections have a Mu-law or A-law option for voice and operate as 64-kbps clear data channels. The packet-switched channels support the LAPD protocol and conform with the CCITT Q.920 Recommendations for D-channel signaling.

The MM720 BRI Media Module provides 8 S/T ISDN 2B+D ports that interface to either the central office or another PBX. The MM720 contains eight, 4-wire ports that interface to the network at the ISDN S/T reference point over two 64 Kb/s channels (B1 and B2) and over a 16Kb/s signaling (D) channel. The B1 and B2 channels can be simultaneously circuit switched, or individually packet switched. Only one channel per trunk can be packet switched due to Packet Processing Element (PPE) limitations. The D-channel is circuit switched. The circuit-switched connections have a Mu-law or A-law option for voice and operate as 64Kb/s clear data channels.

## Error log entries and recommended actions

Table 255: TBRI-PT Error Log Entries 1 of 2

| Error Type | Aux Data | Associated Test                           | Alarm Level | On/Off Board | Recommended Action        |
|------------|----------|-------------------------------------------|-------------|--------------|---------------------------|
| 0 (a)      | 0        | Any                                       | Any         | Any          | <i>test port location</i> |

**Table 255: TBRI-PT Error Log Entries 2 of 2**

| Error Type      | Aux Data | Associated Test                                         | Alarm Level | On/Off Board | Recommended Action |
|-----------------|----------|---------------------------------------------------------|-------------|--------------|--------------------|
| 3841 - 3942 (y) |          | See <a href="#">Aux Data Values for Error 3841-3942</a> |             |              |                    |
|                 |          |                                                         |             |              | <b>2 of 2</b>      |

Notes:

- a. **Error Type 0:** run the short test sequence first. If every test passes, run the long test sequence. Refer to each appropriate test's description, and follow its recommended procedures.
- b. **Error Type 1:** loss of continuity of Layer 1 to the far end. It is assumed that Layer 1 remains active, even when both B-channels are idle.  
  
This test determines whether Layer 1 is active or not. If Layer 1 is not active, the test attempts to activate it. If Layer 1 cannot be activated, the port is taken out of service, and the test fails.
- c. **Error Type 129:** the far-end switch changed the ISDN service state. The trunk is out of service on the far end. This may be a temporary condition.
- d. **Error Type 257:** the D-channel failed at Layer 2. Expiration of this timer indicates that attempts to bring the failed link back into service have not succeeded and some recovery actions should be taken on the associated B-channels. Upon expiration, associated in-service B-channels are put in the out-of-service/far-end state. The timer is cleared when layer 2 is re-established.
- e. **Error Type 513:** on-board hardware failure. The FIFO RAM buffers have overflowed, indicating a hardware problem. The circuit pack is having problems transmitting data to the packet bus.
- f. **Error Type 514:** transmit FIFO Overflow - This error indicates that the circuit pack is having problems transmitting data to the TDM D-channel. This error only occurs on a system that switches the packet implementation of the D-channel over the TDM bus. This error indicates an on-board problem related to the packet implementation of the D-channel.
- g. **Error Type 769:** the port is generating too many uplinks. The link is being suspended. If too many hyperactive events occur with a certain time, the port is alarmed and taken out of service.
- h. **Error Type 1025:** an expired timer has created an unexpected event. The timer could be any of the following:

| Timer | Event              |
|-------|--------------------|
| T3031 | ISDN T3031 timeout |
| T3032 | ISDN T3032 timeout |

|       |                         |
|-------|-------------------------|
| T305  | ISDN T305 timeout       |
| T3081 | ISDN T3081 timeout      |
| T3082 | ISDN T3082 timeout      |
| TL3   | Status Inquiry          |
| T304  | Setup ACK               |
| T310  | Call Proceeding Receive |
| T313  | Connect SEND            |

- i. **Error Type 1281:** this error occurs when the BRI NPE Crosstalk test (#617) has failed. The test will be repeated every 15 minutes until it passes. Follow normal trouble shooting procedures for [BRI NPE Crosstalk Test \(#617\)](#). If this does not fix the problem, follow normal escalation procedures.
- j. **Error Type 1537:** the board received a bad Cyclical Redundancy Check (CRC) over the D-channel. This error is reported on a per-port basis. When the CRC errors exceed 5 within 15 minutes, the port is taken out of service for 5 seconds. If 5 more CRC errors are received within 15 minutes of the first set of 5 errors, the port is taken out of service for 1 minute. If 5 more CRC errors are received within 15 minutes of the previous 5, the port is taken out of service for 15 minutes.
- This error is most likely due to a problem with backplane wiring, a noise source, or no termination (an open circuit). It usually does not indicate a problem with the circuit pack.
1. Check the backplane wiring.
  2. If the problem persists escalate the problem.
- k. **Error Type 1538:** this error occurs when a frame with a bad CRC is received over the TDM D-channel by the BRI trunk board. This error only occurs on a system that switches the packet implementation of the D-channel over the TDM bus. This error indicates an off-board problem related to the packet implementation of the TDM D-channel.
- l. **Error Type 1793:** the BRI Port Local TDM Looparound test (#619) failed. Run the long test sequence, and check the results of the [BRI Port Local TDM Looparound Test \(#619\)](#).
- m. **Error Type 2049:** the [BRI Layer 3 Query Test \(#1243\)](#) has determined that the signaling link is down (Layer 2). The test is repeated every 15 minutes until it passes.
- n. **Error Type 2305:** the [BRI Layer 3 Query Test \(#1243\)](#) failed. The test is repeated every 15 minutes until it passes.
- o. **Error Type 2561:** loss of Layer 1 in stable configuration. The BRI port is configured as stable but the [Trunk-side Layer 1 Query Test \(#1242\)](#) failed 6 times within one hour. Change the **layer 1 stable** field on the `change bri-trunk-board <board location>` screen to **n**.
- p. **Error Type 3073:** a frame of information had to be repeated or deleted. Slips usually occur when the received bit rate is not synchronized with the TDM bus clock.
- q. **Error Type 3585:** the circuit pack detected an overflow of its receive buffers. This error occurs only a system that switches the packet implementation of the D-channel over the

TDM bus. This error indicates an on-board problem related to the packet implementation of the TDM D-channel. This error is logged only.

- r. **Error Type 3586:** each port can support up to three Terminal Endpoint Identifiers (TEIs). Each channel on the port can request a TEI assignment from the switch if it supports ISDN-BRI TEI assignment procedures. If switch services gets a request for a fourth TEI on a port, it reports this event to maintenance software and initiates TEI check procedures on the port. Check to see if the correct number of channels are administered for this port.  
  
The user side supports automatic TEI assignment by the network. Both fixed and automatic TEI assignment are supported on the network side.
- s. **Error Type 3587:** Service Profile Identifier (SPID) value is invalid or is a duplicate of another SPID that is already initialized at Layer 3 on the port. SPIDs are not used on the circuit pack. However there will be related events.
- t. **Error Type 3588:** the board receives D-channel data from the bus faster than it can process the data. The FIFO RAM buffers overflowed. This error occurs occasionally due to the statistical sizing of the buffers; however, frequent occurrences may indicate a LAPD parameter mismatch between the two endpoints of a packet-switched connection. Run the long test sequence, and note the results of the [Receive FIFO Error Counter Test \(#625\)](#).
- u. **Error Type (3589):** the [BRI Port Local LAN Looparound Test \(#618\)](#) failed. Run the long test sequence, and note the results of Test #618.
- v. **Error Type 3590:** an activated BRI port receives a frame containing a DLCI over a D-channel for which it does not have a translation. This error normally indicates an off-board problem related to a state mismatch between the far end and the switch. This error is logged only.
- w. **Error Type 3591:** the circuit pack received a frame containing a DLCI over the TDM D-channel for which it does not have a translation. This error occurs only on a system that switches the packet implementation of the D-channel over the TDM bus, and indicates an off-board problem related to the state mismatch between the board and the packet implementation of the TDM D-channel. This error is logged only.
- x. **Error Type 3592:** the port is generating too many uplinks and is taken out of service for a period of time.
- y. **Error Types 3841–3942:** [Table 256: Aux Data Values for Error 3841–3942](#) contains the received ISDN cause values for Errors 3841–3942 that are recorded in the error log. Unless

otherwise stated, the cause values are D-channel events. The Aux Data field shows which port caused the error.

**Table 256: Aux Data Values for Error 3841–3942**

| Aux Data Value | Type of Problem | Meaning                                           |
|----------------|-----------------|---------------------------------------------------|
| 2              | admin           | No route to specific transit network              |
| 3              | admin           | No route to destination (or Germany bcap not imp) |
| 6              | admin           | Channel unacceptable                              |
| 18             | switch problems | No user responding                                |
| 38             | switch problems | Network failure                                   |
| 50             | subscription    | Requested facility not subscribed                 |
| 52             | admin           | Outgoing calls barred                             |
| 54             | admin           | Incoming calls barred                             |
| 62             | subscription    | Service not authorized                            |
| 63             | admin/sub       | Service/option not available                      |
| 65             | admin/sub       | Bearer capability not implemented                 |
| 66             | admin/sub       | Channel type not implemented                      |
| 69             | admin/sub       | Requested facility not implemented                |
| 70             | admin/sub       | Only restricted digital BC available              |
| 79             | admin           | Service/option not implemented                    |
| 88             | admin           | Incompatible destination                          |
| 102            | switch problems | Recovery on timer expired                         |
|                |                 |                                                   |

1. D = Destructive; ND = Nondestructive

## TBRI-TRK (ISDN Trunk-Side BRI Channel)

| MO Name in Log        | Alarm Level      | Initial Command to Run                | Full Name of MO             |
|-----------------------|------------------|---------------------------------------|-----------------------------|
| TBRI-TRK <sup>1</sup> | MAJ <sup>2</sup> | <code>test trunk location long</code> | ISDN Trunk-Side BRI Channel |
|                       | MIN              |                                       |                             |
|                       | WRN              | <code>test trunk location</code>      |                             |

1. For additional repair information for the TN2185 circuit pack, also see [TBRI-BD \(ISDN Trunk-Side BRI Circuit Pack\)](#) and [TBRI-PT \(ISDN Trunk-Side BRI Port\)](#). For additional repair information for the MM720 BRI Media Module, see [MG-BRI \(BRI Trunk Media Module\)](#) and [TBRI-PT \(ISDN Trunk-Side BRI Port\)](#)

2. A MAJOR alarm on a trunk indicates that alarms on these trunks are not downgraded by `set options` and that at least 75 percent of the trunks in this trunk group are alarmed.

The TBRI-TRK maintenance object is a port on both the TN2185 Trunk-Side BRI circuit pack and the MM720 BRI Media Module. The term *circuit pack* in the following description refers to both the circuit pack and the media module.

The *location* on the TN2185 Trunk-Side BRI circuit pack is UUCSSpp designation.

The *location* on the MM720 BRI Media Module is designated by GGGVSP. Consult local records for the location and designation of the equipment rack where the Media Gateway is mounted.

The TN2185 circuit pack contains eight, 4-wire ports that interface to the network at the ISDN S/T reference point over two 64-kbps channels (B1 and B2) and over a 16-kbps signaling (D) channel. The B1 and B2 channels can be simultaneously circuit-switched, or individually packet-switched. Only one channel per trunk can be packet-switched due to PPE (Packet Processing Element) limitations. The D-channel is either circuit- or packet-switched. Packet switching uses the PPE to combine all D-channels into a single physical channel, which is then routed via the concentration highway to the NCE (Network Control Element) and then to the TDM bus. The circuit-switched connections have a Mu-law or A-law option for voice and operate as 64-kbps clear data channels. The packet-switched channels support the LAPD protocol and conform with the CCITT Q.920 Recommendations for D-channel signaling.

The MM720 Media Module provides 8 S/T ISDN 2B+D ports that interface to either the central office or another PBX. The MM720 contains eight, 4-wire ports that interface to the network at the ISDN S/T reference point over two 64 Kb/s channels (B1 and B2) and over a 16Kb/s signaling (D) channel. The B1 and B2 channels can be simultaneously circuit switched, or individually packet switched. Only one channel per trunk can be packet switched due to Packet Processing Element (PPE) limitations. The D-channel is circuit switched. The circuit-switched connections have a Mu-law or A-law option for voice and operate as 64Kb/s clear data channels.

**Note:**

Not all tests that run on circuit packs are applicable to media modules. These tests will abort with error code 1412. This error can be ignored.

## Error log entries and recommended actions

**Table 257: TBRI-TRK Error Log Entries**

| Error Type | Aux Data | Associated Test            | Alarm Level | On/Off Board | Recommended Action        |
|------------|----------|----------------------------|-------------|--------------|---------------------------|
| 0 (a)      | 0        | Any                        | Any         | Any          | <i>test port location</i> |
| 513 (b)    |          | Service State Audit (#256) | WRN         | OFF          |                           |
| 1793 (c)   | 8, 9     |                            | WRN         | OFF          |                           |
| 3073 (d)   |          | Service State Audit (#256) |             |              |                           |
| 3585 (e)   |          |                            |             |              |                           |
| 3841 (f)   |          |                            | WRN         | OFF          |                           |

**Notes:**

- a. **Error Type 0:** run the Short Test Sequence first. If all tests pass, run the Long Test Sequence. Refer to the appropriate test description and follow the recommended procedures.
- b. **Error Type 513:** the far-end has reported that this channel is not administered. The trunks are placed in the out-of-service state.
- c. **Error Type 1793:** the signaling link is down:
  - 1 Aux Data 8 indicates the Signaling Link is down.
  - 1 Aux Data 9 indicates the Port is out of service.
- d. **Error Type 3073:** the Service State Audit failed. The test will be run every 15 minutes until it passes.
- e. **Error Type 3585:** unexpected Restart message. This error is logged only. No action is necessary.
- f. **Error Type 3841:** B-channel Rejection Event. This action causes the Service State Audit, the Call State Audit, and the Test Call Audit to be executed.

## TDM-BUS (TDM Bus)

| MO Name | Alarm Level       | Initial Command to Run <sup>1</sup> | Full Name of MO |
|---------|-------------------|-------------------------------------|-----------------|
| TDM-BUS | MAJ<br>MIN<br>WRN | <code>test tdm P</code>             | TDM bus         |

1. *P* is the port network number. Use `list cabinet` to find the port network(s) contained in a cabinet.

---

## Description

Each port network has a pair of TDM buses, designated TDM bus A and TDM bus B, each with 256 time slots. This division allows for duplication of control channels and dedicated tone time slots. The first five time slots on each bus are reserved for the control channel, which is active on only one bus at a time in each port network. The next 17 time slots are reserved for system tones such as dial tone, busy tone and so on. As with the control channel, these time slots are active on only one bus, A or B, at a time. The rest of the time slots on each bus are for general system use such as carrying call-associated voice data. The 17 dedicated tone time slots that are inactive can also be used for call processing when every other available time slot is in use.

When the system initializes, the control channel is on TDM bus A and the dedicated tones on TDM bus B in each port network. If a failure occurs on one of the two buses, the system will switch any control, tone and traffic channels to the other bus. Service will still be provided, though at a reduced capacity.

The `set tdm PC` command has the effect of putting both the control channel and tone time slots on a specified bus, A or B. *P* specifies the port network's number, and *C* specifies the TDM bus, A or B. Throughout this discussion, *PC* refers to a specific TDM bus. References to *port circuit packs* include every circuit pack that terminates on the TDM bus, including the Expansion Interface TN570, and the following service circuit port boards: Call Classifier (TN744), Integrated announcement (TN750), Maintenance/Test (TN771), Speech Synthesizer (TN725B), Tone Detector (TN748 or TN420). Other terms used are:

- 1 Control Channel Bus: the TDM bus carrying the active control channel
- 1 Non-Control Channel Bus: the TDM bus with the inactive control channel
- 1 Tone Bus: the TDM bus carrying the active tone time slots
- 1 Non-Tone Bus: the TDM bus with the inactive tone time slots

---

## TDM-Bus Fault Detection and Isolation

TDM-bus faults are usually caused by one of the following:

- 1 A defective circuit pack connected to the backplane
- 1 Bent pins on the backplane
- 1 Defective bus cables or terminators

It is possible that a circuit pack can cause a TDM-bus fault and still exhibit trouble-free operation. For example, insertions of any circuit pack into a slot with TDM bus terminations may bend the backplane pins and short two leads together. Since the TDM bus is a shared resource, identification of the cause of a TDM-bus fault can be difficult. If a TDM-bus problem is suspected, run `test tdm B`. If any of the resulting tests fail, you must perform a manual TDM bus isolation procedure to identify the cause of the problem.

Since the procedure for isolating TDM-bus faults involves removing circuit packs and possibly disconnecting entire carriers, the procedure is extremely destructive to the port network that contains the TDM bus being tested. If possible, arrange to perform this procedure at a time when traffic is minimal.

As circuit packs are removed or entire carriers are disconnected, any active calls terminating on those circuit packs or carriers will be dropped. If you have any hints about a particular circuit pack that may be causing the TDM bus problem investigate those before performing this procedure (for example, look at any circuit packs that were inserted into the PN just before the TDM bus problem appeared).

When straightening or replacing backplane pins in a carrier that contains a CFY1B Current Limiter, power to the *cabinet* must be removed. When straightening or replacing backplane pins in a carrier that does NOT contain a CFY1B Current Limiter, power to that *carrier* must be shut off. Failure to follow this procedure may result in damage to circuit packs and power supplies, and can be hazardous to the technician.

**Note:**

Maintenance software requires TN748 or TN420 Tone Detector, or TN2182 Tone Clock, or TN2312 IPSI circuit pack to test the TDM bus. Before starting these procedures, make sure that one of these is installed in the port network being investigated.

---

## Procedure 1: Isolating TDM-Bus Faults

This procedure is an attempt to isolate the TDM-bus fault to circuit packs that are essential to the system's operation. For each of the following circuit packs in the port network where the TDM-bus fault appears, perform Procedure 1.

| Circuit Pack        | Error Log Names               |
|---------------------|-------------------------------|
| Tone-Clock          | TONE-BD, TONE-PT, and TDM-CLK |
| Tone Detector       | DETR-BD, GPTD-PT, and DTMR-PT |
| Expansion Interface | EXP-INTF                      |
| Packet Interface    | PKT-INT                       |

1. Display the Alarm Log for the circuit pack using `display alarms`.
2. If there are alarms for the circuit pack, refer to that section and try to resolve the alarms.
3. Whether or not every alarm can be cleared, test the TDM bus again using `test tdm P`.
4. If some TDM-bus tests fail, implement Procedure 1 for the next circuit pack.
5. If every TDM-bus test passes, the problem has been fixed.
6. If every circuit pack in the list has been investigated, go to Procedure 2.

---

## Procedure 2: Removing and Reinserting Port Circuit Packs

Procedure 2 removes and reinserts port circuit packs (those in the carrier's purple slots) one or more at a time. Use this procedure for each port circuit pack in the port network until the problem is resolved or until every circuit pack in the port network have been tried. To execute diagnostic procedures on the Expansion Interface and Tone-Clock circuit packs, see [Procedure 3: Removing and Reinserting PN Control Circuit Packs](#). Although these circuit packs reside in purple slots, procedure 2 does not apply. This procedure *does* apply to the Tone Detector circuit pack.

If the TDM bus problem is present when the circuit pack is inserted, but is resolved when the circuit pack is removed, either the circuit pack or the backplane pins in that slot are causing the problem. If the backplane pins are intact, replace the circuit pack. If some of the tests fail regardless of whether the circuit pack is inserted or removed, and the backplane pins are intact, the circuit pack is not the cause of the problem. In a multiple failure situation, the circuit pack could be one cause of the TDM bus problem. However, other simultaneous failures might also be responsible for TDM-bus faults.

In Procedure 2, an option of working either with one circuit pack at a time or with multiple circuit packs simultaneously is available. In view of this capability, determine the level of service interruption that will be acceptable during the procedure. If causing a disruption to all users in the port network is deemed permissible, large groups of circuit packs should be worked with in order to get the job done quickly. However, *if large service disruptions are to be avoided*, work with one circuit pack at a time. This option is slower, but it disrupts only the users of a single circuit pack.

1. Remove one or several circuit packs as appropriate. Any circuit packs that reside on the TDM bus that were recently inserted should be checked first.

Remove port circuit packs which have failed the NPE Crosstalk Test (#6) first. To find which circuit packs failed this test, display the Error Log via the `display errors` command. Refer to the Maintenance documentation of each port circuit pack that has port errors to check if any error indicates the failure of the NPE Crosstalk Test. If no circuit pack failed the NPE Crosstalk Test (#6), remove one or several purple slot circuit packs.

If you decide to remove multiple circuit packs, consider working with an entire carrier at a time to more quickly and reliably determine which circuit packs are not the source of trouble.

2. Run `test tdm P` to determine if the TDM-bus fault is still present.
3. If any of the TDM-bus tests fail:
  - 1 Determine whether the backplane pins in the removed circuit pack's slot appear to be bent.
  - 1 If the backplane pins are not bent, reinsert the circuit pack(s), and perform Procedure 2 for the next set of circuit packs.
  - 1 If the backplane pins are bent, remove power to this carrier in the mer described previously.
  - 1 Straighten or replace the pins and reinsert the circuit pack.
  - 1 Restore power and repeat Procedure 2, beginning with Step 2, for the same circuit pack(s).
4. If none of the TDM-bus tests fail:
  - 1 Reinsert the circuit pack(s) *one at a time*, and repeat the following substeps until every circuit pack has been reinserted.
  - 1 Run `test tdm P` to determine if the TDM-bus fault has returned.
  - 1 If any of the TDM-bus tests fail, the reinserted circuit pack is defective. Replace this circuit pack and repeat this procedure for the next circuit pack.
  - 1 If none of the TDM-bus tests fail when every circuit pack has been reinserted, the problem has been fixed and the procedure is completed.

Continue with Procedure 3 if every port circuit pack has been checked, but the TDM-bus fault is still not resolved.

---

## Procedure 3: Removing and Reinserting PN Control Circuit Packs

This procedure removes and reinserts a PN's control circuit packs. Use this procedure to test:

1. TN570 Expansion Interface
1. TN768, TN780, or TN2182 Tone Clock, or TN2312 IPSI

Check the Tone-Clock circuit pack next-to-last. Check the Expansion Interface circuit pack (TN570) last, because removing this circuit pack disconnects its PN. In a system with duplicated PNC, disruption of traffic can be minimized by following the procedure for the standby TN570 Expansion Interface circuit pack, and then entering `reset pnc interchange`. The formerly active Expansion Interface will be standby and can be checked without affecting the PN's service.

For instructions, at each step in a procedure that requires the removal and/or replacement of a circuit pack, refer to the documentation for the specific circuit pack's MO. Server and/or PNC interchanges may be required to complete these steps with the least amount of service disruption.

### Procedure for PN with Unduplicated PNC

1. Remove the suspected circuit pack.
2. As in [Procedure 2: Removing and Reinserting Port Circuit Packs](#), determine if the backplane pins on the back of the removed circuit pack's slot are bent.
3. If the backplane pins are bent, do the following:
  - a. Power down the control carrier as described in the previous warning statement.
  - b. Straighten or replace the pins.
  - c. Insert the same circuit pack.
  - d. Turn the power back on to reboot the system or to restart the PN.
  - e. Run `test tdm P` to determine whether the TDM-bus fault still exists.
  - f. If none of the TDM-bus tests fail, the procedure is complete.
  - g. If some of the TDM-bus tests fail, replace the suspected circuit pack, and go to step 4.If not: Replace the circuit pack and turn the power back on to reboot the system.
4. Run `test tdm P` to determine whether the TDM-bus fault is still present.
5. If the TDM-bus fault is still present, the suspected circuit pack was not the cause of the TDM-bus failure. Do the following:
  - a. Remove the replacement circuit pack that was just inserted and replace it with the previously suspected circuit pack.
  - b. Repeat Procedure 3 for the next circuit pack on the list for this procedure.If none of the TDM-bus tests fail, the procedure is completed.

If Procedure 3 fails to identify the cause of the problem, go to [Procedure 4: Isolating TDM-Bus Failures to Carriers](#).

---

### S8700-series Fiber-PNC

## Procedure for PN with Duplicated PNC

In this type of configuration, the test procedure is made up of several independent parts. In a duplicated system, it is desirable to investigate whether circuit packs are causing TDM-bus problems when they are in active mode, in standby mode, or both. The procedure utilizes a PNC interchange in a PN. If the TDM-bus fault disappears after an interchange takes place, the newly standby Expansion Interface (PN), is suspect and should be replaced. If the problem still exists, the Tone-Clocks are then interchanged. If the TDM-bus failure then disappears, the newly standby Tone-Clock is suspect and should be replaced. If the TDM-bus problem still exists, then the procedure begins diagnostics on individual circuit packs and backplane pins.

### Part 1 (PN Procedure)

1. Execute `status pnc` to determine which PNC is currently active.
2. Run `reset pnc interchange` to make the currently active PNC standby.
3. Run `test tdm P` to determine whether the TDM-bus fault is still present.  
If the TDM-bus fault is gone, replace the formerly active Expansion Interface circuit pack.
4. Run `reset pnc interchange` again to activate the PNC where the new Expansion Interface circuit pack resides.
5. Run `test tdm P` to determine whether the TDM-bus fault is still present.  
If the TDM-bus fault is gone, the procedure is finished.  
If not, replace the new Expansion Interface circuit pack with the originally suspected circuit pack, and continue with Part 2.

### Part 2

1. Run `set tone-clock` to make the currently active Tone-Clock standby.
2. Run `test tdm P` to determine whether the TDM-bus fault is still present.  
If the TDM-bus fault is gone:
  - a. Replace the formerly active Tone-Clock circuit pack.
  - b. Run `set tone-clock` again to make the new Tone-Clock circuit pack active.
  - c. Run `test tdm P` to determine whether the TDM-bus fault is still present.
 If the TDM-bus fault is still present, replace the new Tone-Clock circuit pack with the originally suspected circuit pack, and continue with Part 3.

### Part 3

Use Part 3 for each individual circuit pack listed in the previous table. Run this procedure on every circuit pack in the standby PNC. If the TDM-bus failure still exists (once every standby circuit pack has been tested), execute `reset pnc interchange`, and `set tone-clock` to put the currently active circuit packs into standby mode so that this procedure can be run on each of them.

1. Remove the inactive suspected circuit pack.
  2. As in Procedure 2, determine whether any backplane pins on the back of the removed circuit pack's slot are bent.
  3. If the pins are bent, do the following:
    - a. Remove power as described in the previous warning statement.
    - b. Straighten or replace the pins.
    - c. Restore power.
    - d. Run `test tdm P` to determine whether the TDM-bus fault is still present.

If the TDM-bus failure is still present, the problem is with another circuit pack. Reinsert the originally suspected circuit pack, and repeat Part 3 for the next circuit pack.
    - e. If the TDM-bus failure has disappeared, reinsert the circuit pack and run `test tdm P` to see if the TDM-bus failure is still present.

If any of the TDM-bus tests fail, replace the suspected circuit pack. The procedure is finished.

If not, the procedure is finished.
    - f. If any of the TDM-bus tests fail, the problem is with another circuit pack. Reinsert the originally suspected circuit pack, and repeat Part 3 for the next circuit pack.
    - g. If not, replace the suspected circuit pack. The procedure is finished.
  4. If every standby circuit pack has been tested but the TDM-bus failure still exists, execute `reset pnc interchange` and `set tone-clock` to put the currently active circuit packs into standby mode. Repeat Part 3 of this procedure for each of the newly active circuit packs.
- 

### Procedure 4: Isolating TDM-Bus Failures to Carriers

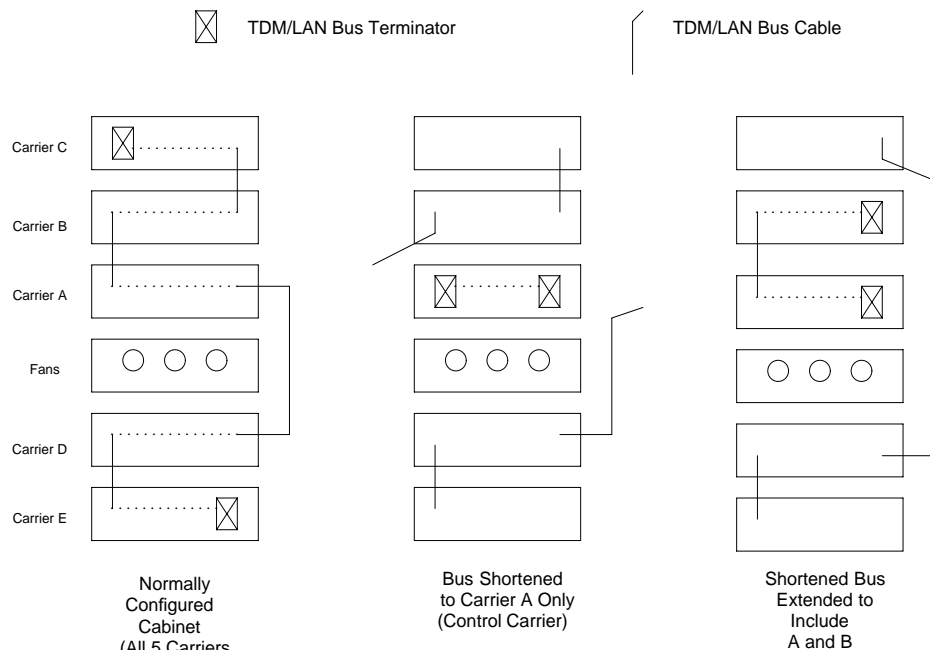

Procedure 4 attempts to isolate a TDM-bus failure to a particular set of carriers. Only the circuit packs in selected carriers are checked. Procedure 4 is used if the preceding procedures fail, because it can help locate failures of:

- 1 Multiple circuit packs
- 1 The carrier's hardware itself

In this procedure, the TDM/LAN cable assemblies and TDM/LAN bus terminators are replaced.

If replacement does not resolve the TDM-bus fault, the cabinet is reconfigured so that certain carriers are disconnected from the TDM bus. This is done by moving the TDM/LAN bus terminators (ZAHF4) on the carrier's backplane. To terminate a TDM bus at the end of a particular carrier, the TDM bus cable that connects the carrier to the next carrier should be unplugged and replaced with a TDM/LAN bus terminator (see [Figure 87](#)). As the length of a TDM bus is *modified*, any essential circuit packs to the system's operation and TDM-bus maintenance (for example, Tone-Clock), must still be connected to the *shortened* TDM bus.

**Figure 87: Carrier Rewiring Example — Rear View of 5-Carrier Cabinet**

After cabling changes are made and verified, power must be restored to the PN. Circuit packs in carriers outside the shortened bus are not inserted. As a result, these circuit packs are alarmed. Ignore these alarms for now. Every alarm should be resolved when the cabinet is restored to its original configuration.

Procedure 4 is organized into two parts. Part 1 attempts to clear a TDM-bus fault by replacing every bus cable and terminator within a PN. Part 2 attempts to isolate the fault to a particular carrier by extending the TDM bus from the control carrier to additional carriers one at a time.

Power must be removed from the entire PN before any cables or terminators are removed. Failure to follow this procedure can cause damage to circuit packs and power supplies, and can be hazardous to the technician.

### Part 1

1. If spare TDM/LAN cable assemblies and TDM/LAN bus terminators are not available, go to Part 2 of this procedure.
2. Power down the PN.
3. Replace every TDM/LAN cable assembly and both TDM/LAN bus terminators.
4. Restore power to the PN.
5. Run `test tdm P` to determine whether the TDM-bus fault is still present.
6. If the TDM-bus fault is resolved, the procedure is finished. Otherwise, continue with Part 2.

### Part 2

1. Terminate the TDM bus so that it extends only across the carrier that contains the active Expansion Interface.
2. Run `test tdm P` to determine whether the TDM-bus fault is still present.

If the *shortened* TDM bus does not extend to a carrier continuing the Tone Detector circuit pack, the:

- 1 Non-control channel test (#297) will not be able to run
- 1 Bus that the non-control channel was on will not be tested

If this is the case, run `set tdm PC` to move the control channel to the non-active bus. The `status port-network P` command shows which bus is currently active. After the bus switch has occurred, run `test tdm P` again to determine whether the newly active bus is faulted.

Another option is to move a Tone Detector circuit pack to an empty slot, if one is available, in the carrier where the TDM bus is terminated. This would:

- 1 Allow both the control channel and non-control channel tests to run
  - 1 Not require `set tdm P` command to be run
3. If none of the TDM-bus tests fail, extend the TDM bus to another carrier, and repeat the procedure in the previous step. When a carrier that causes the fault to recur is added, perform Procedure 2 for only the circuit packs in that carrier.
  4. If any of the TDM-bus tests fail and Procedures 2 and 3 did not resolve the problem, the added carrier(s) are defective and must be replaced.

## Restarting Non-Functioning Port Circuit Packs

A defective TDM-bus control channel or system-timing reference on one of the EPNs can cause port circuit packs residing outside the PN's control carrier to enter the reset state. When this situation occurs, the circuit pack will stop functioning, and its red LED will light. The system does not detect the presence of a circuit pack when it is in the reset state. Executing `list config board` shows that the circuit pack is absent.

If a circuit pack enters the reset state, it remains out of service until it receives a restart message from the control channel on the same TDM bus (A or B) that was active when it reset, or until it is powered up again.

To force the system to send a restart message to every circuit pack on a network, try one of the following methods, depending on the circumstances. Any normally functioning circuit pack (i.e., not in reset state) will ignore the restart message.

### Procedure 1 (Nondestructive)

If the control channel is on the same TDM bus as it was when the circuit pack entered the reset state, Enter `test tdm P` to execute the Idle Time Slot test (#294).

### Procedure 2 (Nondestructive)

If you are on-site, reseal the circuit pack. This action causes the circuit pack in the reset state to begin functioning on the control channel of the *current* bus.

### Procedure 3 (Destructive)

Enter the `reset port-network P level 2` command to reset the PN containing the circuit pack in the reset state. During a PN reset, two restart messages (one on the control channel of each TDM bus) are sent to each circuit pack in the PN. Resetting the PN disrupts every call going to and originating from the PN.

### Procedure 4 (Destructive)

Execute `recycle carrier PC`. This command removes and restores power to the designated port carrier. Thus, any other circuit packs in this carrier will also be temporarily taken out-of-service.

## Error log entries and recommended actions

**Table 258: TDM-BUS Error Log Entries**

| Error Type | Aux Data | Associated Test             | Alarm Level | On/Off Board | Recommended Action          |
|------------|----------|-----------------------------|-------------|--------------|-----------------------------|
| 0          | 0        | Any                         | Any         | Any          | <code>test tdm P</code>     |
| 1          | 0        | Control Channel test (#296) | MIN         | ON           | <code>test tdm P r 3</code> |
| 18 (a)     | 0        | <code>busyout tdm PC</code> | WRN         | ON           | <code>release tdm PC</code> |
| 35 (b)     | 0-1      | TDM bus Corruption          | MIN         | ON           | <code>set tdm PC</code>     |
| 257 (c)    | 0        |                             | MAJ         | ON           |                             |
| 513 (d)    | Any      | Idle Time Slot test (#294)  | MIN         | ON           | <code>test tdm P r 3</code> |
| 769 (e)    | Any      | Idle Time Slot test (#294)  | WRN         | ON           | <code>test tdm P r 3</code> |
| 769 (f)    | Any      | Idle Time Slot test (#294)  |             |              | (see Notes)                 |
| 1025 (g)   | Any      |                             |             |              |                             |
| 3872 (h)   | Any      |                             |             |              |                             |
| 3873 (h)   | Any      |                             |             |              |                             |
| 3874 (h)   | Any      |                             |             |              |                             |
| 3877 (h)   | Any      |                             |             |              |                             |

Notes:

- a. **Error Type 18:** the TDM bus has been busied out by the technician. The error will retire when the technician releases the TDM bus.
- b. **Error Type 35:** this error indicates the TDM bus is corrupted. If the corruption was on the Control Channel bus, TDM bus maintenance automatically switches the control channel and/or tones to the other bus. The same strategy applies if the corruption was on the bus carrying the tones.

An Aux Data value of 0 indicates the last reported TDM bus corruption was on the Control channel bus.

An Aux Data value of 1 indicates the last reported TDM bus corruption was on the Non-Control channel bus.

- c. **Error Type 257:** this error indicates the TDM bus was switched to the other bus due to TDM bus corruption. The Aux Data value is not meaningful and no action is required. Look for other TDM-BUS errors to determine the cause of this error.
- d. **Error Type 513:** some time slots are corrupted in the specified TDM bus. The Minor alarm is raised when there are more than 50 bad time slots in the bus. The Aux Data indicates the number of bad time slots found by the test.
- e. **Error Type 769:** some time slots are corrupted in the specified TDM bus. The Warning alarm is raised when there are more than 10 bad time slots but less than or up to 50 bad ones in the bus. The Aux Data value indicates the number of bad time slots found by the test.
- f. **Error Type 769:** the idle time slot test found less than 10 bad time slots in the TDM bus. The Aux Data value indicates the number of bad time slots found by the test. There is no alarm associated with this error.
- g. **Error Type 1025:** the daily TDM bus switch was not successful. The active Expansion Interface (PN) cot talk on the bus that software was trying to switch into. There is no alarm associated with this error.
- h. **Error Type 3872, 3873, 3874, and 3877:** these errors indicate communication problems which may be causing message loss. TDM bus maintenance may switch the Control channel bus and/or Tone bus to the other bus. Test the TDM bus using `test tdm P` and follow the procedures according to the Error Codes reported from the test. The Aux Data value shows the Angel ID number for which a downlink message was lost.

---

## Demand test descriptions and error codes

Investigate tests in the order presented. By clearing errors associated with the first test, errors generated from other tests may also be cleared. Click on the link to see the full description of the test, error codes, and recommended actions.

| Order of Investigation                          | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|-------------------------------------------------|---------------------|--------------------|-------------------|
| <a href="#">Control Channel Test (#296)</a>     | X                   | X                  | ND                |

## TDM-CLK (TDM Bus Clock)

| MO Name in Log | Alarm Level | Initial Command to Run                   | Full Name of MO |
|----------------|-------------|------------------------------------------|-----------------|
| TDM-CLK        | MAJ<br>MIN  | <code>test tone-clock location</code>    | TDM bus Clock   |
|                | WRN         | <code>release tone-clock location</code> |                 |

**Note:**

Replacing the Tone-Clock circuit pack or the IPSI requires a special procedure described in the documentation for [TONE-BD \(Tone-Clock Circuit Pack\)](#). That section also describes the LED displays for these circuit packs.

The Time Division Multiplex (TDM) Bus Clock resides on the Tone-Clock circuit, providing clocking signals both for the TDM bus and the LAN Bus. The Tone-Clock circuit is a critical component in the system and is necessary to ensure the operation of every port circuit pack in the system. The TDM buses of every EPNs is synchronized together. The system timing reference can be derived internally from the Tone-Clock circuit in any PN, or from an external (off-board) timing reference. Currently, the TDM bus Clock supports synchronizing the TDM bus with interface rates from Digital Signal 1 (DS1) facilities as primary or primary and secondary references, ([S8700](#) | [S8710](#) | [S8720](#): and from Stratum-3 clock (STRAT-3) facilities. Only the TN780 tone-clock supports a Stratum-3 clock.)

Moreover, the TN2314 Processor/Tone-Clock circuit pack aids in monitoring and selecting synchronization references. The TN2314 Processor/Tone-Clock circuit pack, after detecting that the external source of timing is not valid, will automatically begin its escalation procedure, according to the facilities administered. In the following table, successive losses of signal cause escalation from left to right.

Switching back to a DS1 source is handled by synchronization maintenance, once any problems with it are corrected and tested.

[S8700](#) | [S8710](#) | [S8720](#): However, once synchronization has been switched to the internal timing source of the master Tone-Clock circuit, switching back to a Stratum-3 clock must be initiated by a technician after the external reference has been repaired.

**Table 259: Synchronization - Tone Clock Roles 1 of 2**

| Tone-Clock Role                                                     | Synchronization Facilities | Initial External Synchronization Source | Backup External Synchronization Source | Internal Source  |

| 2305 (k)         | 0        |                                            | WRN              | OFF                       |                                            |
|                  |          |                                            |                  |                           | <b>2 of 2</b>                              |

1. As a general rule, any *on-board* errors against the TDM Bus Clock should be resolved before pursuing any other errors against PNC components. *Off-board* clock errors may be caused by other board errors, and should be addressed after on-board errors have been resolved.

2. Major or Minor alarms on this MO may have been downgraded to Warning based on the values in set options.

Notes:

- a. **Error Type 0:** run the short test sequence first. If every test passes, run the long test sequence. Refer to each appropriate test's description, and follow its recommended procedures.
- b. **Error Type 1:** the IPSI or Tone-Clock circuit pack may have a clock at the edge of its specified frequency. This can cause Expansion Interface circuit packs and SNI circuit packs to go out-of-frame or report no-neighbor conditions. This can in turn cause EPNs, Expansion Archangel Links (EALs), Remote Neighbor Links (RNLs), and/or Local Neighbor Links (LNLs) to go down. When this error is alarmed, the Clock Health Inquiry test (#46) will fail with an Error Code of 1.
  - 1. Replace the IPSI or Tone-Clock circuit pack identified in the error log. See [Replacing the IPSI or Tone-Clock Circuit Pack](#).
- c. **Error Type 18:** the indicated Tone-Clock circuit has been made unavailable using `busyout tone-clock location`. It only applies to systems with the high- or critical-reliability option administered, because only a standby Tone-Clock circuit may be made busy by that command. To resolve this error, execute `release tone-clock location` for the alarmed circuit pack.
- d. **Error Type 130:** the circuit pack has been removed or has been insane for more than 11 minutes. To clear the error, reinsert or replace the circuit pack.

- e. **Error Type 257:** the Tone-Clock circuit pack in PN 1 is not a TN780 although Stratum-3 synchronization is administered. Either:
1. If a Stratum-3 clock is being used, replace this Tone-Clock with a TN780.
  2. If not, change synchronization administration to Stratum 4.
- f. **Error Type 513:** the tone-clock has reported an out-of-lock condition. A aux value of 1 indicates this error is an out-of-lock with the primary reference. An Aux Data value of 2 indicates that this error is an out-of-lock with the secondary reference. It could not lock onto the frequency of that synchronization reference. This will lead to a change in the synchronization reference if the condition continues.

---

[S8700](#) | [S8710](#) | [S8720](#) | [S8500](#)

- g. **Error Type 769:** The IPSI's Tone-Clock circuit or Tone-Clock circuit pack might be defective, however it may be a software failure that can be corrected by testing.
1. Check to see if the board is duplicated (`list cabinet` and `status port-network`) on the affected port network.
  2. If the board is not duplicated, use `test tone-clock location long` to resolve the errors. The long test resets the board and is required to reload on-board RAM associated with the TN2182's DSPs. The effect is that tone detectors are taken out of service momentarily and tones are removed from the TDM bus for about 10 seconds, meaning that no dial tone or touch tones are available during this interval. This will probably not affect calls in progress, but could cause a call origination to abort or a user not to get dial tone when going off-hook.
  3. If every test passes and the alarm does not resolve, retest with `test tone-clock location long clear`.
  4. If the test passes, terminate the repair process. If the test fails, replace the circuit pack at the customer's convenience.
  5. If this error was logged against the standby Tone-Clock, and if the Aux Data value was 18369, SYNC (Synchronization) maintenance acts on this error. No corrective action is required. For any other Aux Data, go to the next step.
  6. If the board is duplicated, switch to the standby side (`set tone-clock`).
  7. Test the alarmed board (`test tone-clock location long`). This resets the board and is required to reload on-board RAM associated with the TN2182's DSPs.
  8. If every test passes and the alarm does not resolve, retest (`test tone-clock location long clear`).
  9. If the test passes, terminate the repair process. If the test fails, replace the circuit pack at the customer's convenience.
-

- h. **Error Type 1025:** Processor/Tone-Clock circuit on-board maintenance has detected one or more clock slips, timing differences between its internal reference source and the synchronization signal provided by the master Tone-Clock. Although no clock slip errors are expected during normal operation, both manual and automatic interchanges of Tone-Clock circuit, synchronization references, and PNCs could result in clock slip counts.

If Error Type 1281 also is logged for the same Tone-Clock circuit, it is related to this problem and should be corrected first. Otherwise, continue with the following procedure.

1. Use `test tone-clock location`, and examine the results of Test #149 to see if slip errors still appear. If no new slip errors are reported, and if these errors are not causing a TDM-CLK alarm, they may be ignored. Use `test tone-clock location long clear` to clear the errors.
2. Otherwise, enter `display errors`, and follow corrective procedures for any other TDM-CLK, TONE-BD, SYNC, DS1C-BD, EXP-INTF, SNC-BD, and SNI-BD errors logged, except for those in [Table 261: Error Log Entries for Slip Errors](#).

**Table 261: Error Log Entries for Slip Errors**

| Circuit Pack Name     | Error Log Name | Error Log Number of Slips |
|-----------------------|----------------|---------------------------|
| DS1 Interface         | DS1-BD         | 3073 to 3160              |
| Expansion Interface   | EXP-INTF       | 2305                      |
| Switch Node Interface | SNI-BD         | 1537                      |
| Tone-Clock            | TDM-CLK        | 1025                      |
| UDS1 Interface        |                | 3073 to 3160              |
| DS1C Circuit Pack     | DS1C-BD        | 3329                      |

3. If Error Type 1025 errors persist, see [SYNC \(Port Network Synchronization\)](#).
- i. **Error Type 1281:** the Processor/Tone-Clock circuit has detected a loss of timing signal from the system's synchronization reference. The Processor/Tone-Clock circuit has switched synchronization references.
    1. Resolve any errors logged against the [SYNC \(Port Network Synchronization\)](#) or [STRAT-3 \(Stratum-3 Clock\)](#) MOs.
    2. See [SYNC \(Port Network Synchronization\)](#), if the error is not resolved by step 1.

**Error Type 1282:** the TN2182 tone-clock was synchronized to a DS1 facility and that the reference frequency provided by the DS1 drifted beyond a range that could be tracked by the TN2182. Therefore the TN2182 is no longer synchronized to that DS1 reference. If a second DS1 is available, the tone-clock may be synchronized to that reference. If no secondary DS1 reference is available, the tone-clock will run off of its internal clock. This may result in slips being reported by the tone-clock and every DS1 facility.

## j. Error Type 2049:

---

### S8700-series Fiber-PNC

The Tone-Clock circuit in the master port network was unable to detect the incoming synchronization signal, but the other tone-clock was able to detect the references. If the Aux Data is 0, the problem is with the signal on the primary. If the Aux Data is 1, the problem is with the signal on the secondary. The system should switch clocks in this situation.

1. If this error is against PN 1's clock board and the system is using a Stratum-3 clock, check the cabling that brings the Stratum-3 signal to this clock board.
  2. Replace the current standby IPSI or Tone-Clock circuit pack. See [Replacing the IPSI or Tone-Clock Circuit Pack](#).
- 

## k. Error Type 2305:

---

### S8700-series Fiber-PNC

The indicated Tone-Clock circuit is an active **slave** Tone-Clock that has detected a loss of timing signal from its EXP-INTF synchronization source. (A slave Tone-Clock resides in a PN that does not contain the system's reference synchronization source.)

1. Enter **display errors** and **display alarms**, and follow the repair procedures for [EXP-INTF \(Expansion Interface Circuit Pack\)](#), [TDM-CLK \(TDM Bus Clock\)](#), and [TONE-BD \(Tone-Clock Circuit Pack\)](#) error log entries that have on-board alarms.
2. If the 2305 errors persist, follow the repair procedures for [EXP-INTF \(Expansion Interface Circuit Pack\)](#) error log entries 257, 769, or 770, or any errors logged against [SNI-BD \(SNI Circuit Pack\)](#), [SNC-BD \(Switch Node Clock Circuit Pack\)](#), or [FIBER-LK \(Fiber Link\)](#).
3. If the 2305 errors persist:
  - a. *For Port Networks with more than one Tone-Clock circuit*, execute **test synchronization r 10** to see if new 2305 errors against TDM-CLK were reported. If not, execute **reset pnc interchange** and **test synchronization r 10** again, and recheck for new 2305 errors against TDM-CLK
  - b. *For Port Networks with a single Tone-Clock circuit*, execute **test synchronization r 10** to see if new 2305 errors were reported.

If no new instances of the 2305 errors were logged for either test, enter **test tone-clock location long clear** to clear the TDM-CLK errors. The procedure is complete.

4. *For Port Networks with more than one Tone-Clock circuit:*
  - a. Enter **set tone-clock location** to interchange the Tone-Clocks.

- b. Run **test synchronization r 10** to see if new 2305 errors are reported against the new active Tone-Clock circuit.
- c. If not, replace the standby Tone-Clock circuit. See [Replacing the IPSI or Tone-Clock Circuit Pack](#).

If this clears the error, the problem has been resolved.

- 5. Replace the EI circuit pack for the active PNC.
- 6. If the problem is still not cleared and the IPSI or Tone-Clock circuit pack reported in the error log has not yet been replaced, replace it. See [Replacing the IPSI or Tone-Clock Circuit Pack](#).

---

## Demand test descriptions and error codes

Investigate tests in the order presented. By clearing errors associated with the first test, errors generated from other tests may also be cleared. Click on the link to see the full description of the test, error codes, and recommended actions.

| Order of Investigation                                           | Short Test Sequence | Long Test Sequence | Reset Board Sequence | D/ND <sup>1</sup> |

1. D = Destructive; ND = Nondestructive

## TDMODULE (Trunk Data Module)

See [PDMODULE \(Processor Data Module\)](#).

## TIE-BD (Tie Trunk Circuit Pack)

| MO Name in Log | Alarm Level | Initial Command To Run     | Full Name of MO        |
|----------------|-------------|----------------------------|------------------------|
| TIE-BD         | MIN<br>WRN  | <i>test board location</i> | Tie Trunk Circuit Pack |

See [XXX-BD \(Common Port Circuit Pack/Media Module\)](#) for circuit-pack level errors.

See [TIE-TRK \(Analog Tie Trunk\)](#) for trunk information.

## TIE-DS1 (DS1 Tie Trunk)

| MO Name in Log       | Alarm Level             | Initial Command to Run                              | Full Name of MO |
|----------------------|-------------------------|-----------------------------------------------------|-----------------|
| TIE-DS1 <sup>1</sup> | MAJ <sup>2</sup><br>MIN | <code>test trunk grp#/mem# long</code> <sup>3</sup> | DS1 Tie Trunk   |
|                      | WRN                     | <code>test trunk grp#/mem#</code>                   |                 |

- For additional repair information, see [DS1-BD \(DS1 Interface Circuit Pack\)](#) if the tie trunk is on a TN722 or TN767 DS1 circuit pack. See [UDS1-BD \(UDS1 Interface Circuit Pack\)](#) UDS1-BD documentation if the tie trunk is on a TN464 UDS1 circuit pack. See [MG-DS1 \(DS1 Interface Media Module\)](#) if the tie trunk is on a DS1 Interface Media Module.
- A MAJOR alarm on a trunk indicates that alarms on these trunks are not downgraded by `set options` and that at least 75% of the trunks in this trunk group are alarmed.
- For TN767B vintage 8 or 9 circuit packs, a failure of Test #136 causes a subsequent failure of Test #7. Test #136 is part of the short sequence and generates off-board alarms. Test #7 is part of the long sequence and generates on-board alarms. Before entering busyout, release, reset or test board long commands, check the vintage number of the circuit pack with `list configuration board location`. If it is TN767B vintage 8 or 9, do not use the above commands until you ensure that Test #136 passes via test board short. Otherwise, extraneous on-board alarms may be generated.

### Note:

Many trunk problems are caused by incorrect settings of parameters on the trunk group administration form. Settings must be compatible with the local environment and with parameter settings on the far end. Refer to the *Administering Avaya Aura™ Communication Manager* for information on how to administer trunks. Refer to your Avaya representative for the correct settings for administrable timers and other parameters on a country-by-country basis.

The DS1 tie trunk provides both voice and data communications between two PBX switches. There are two types of DS1 interfaces:

- 1 24 DS0 channels on a 1.544-Mbps link
- 1 31 DS0 channels + 1 framing channel on a 2.048-Mbps link

### Note:

32-channel mode is supported only on TN464 circuit packs.

DS1 Tie Trunks are used widely in the Distributed Communications System (DCS) and Central Attendant Service (CAS) system features. A DS1 tie trunk can also be used as an access endpoint which is a non-signaling channel with bandwidth for voice-grade data, 56- or 64-kbps data. DS1 tie trunk maintenance provides a strategy to maintain a DS1 tie trunk via a port on the TN722 or TN767 DS1 Interface circuit pack, the TN464 UDS1 Interface circuit pack, or the DS1 Interface Media Module. Throughout this TIE-DS1 section, the term DS1 Interface applies to DS1 or UDS1 circuit packs, or to DS1 Interface Media Modules.

**Note:**

Not all tests that run on circuit packs are applicable to media modules. These tests will abort with error code 1412. This error can be ignored.

The DS1 tie trunk maintenance strategy covers logging DS1 tie trunk hardware errors, running tests for trunk initialization, periodic and scheduled maintenance, demand tests, and alarm escalation and resolution. Three different trunk service states are specified in DS1 tie trunk maintenance:

|                                |                                                                               |
|--------------------------------|-------------------------------------------------------------------------------|
| Out-of-service                 | The trunk is deactivated and cannot be used for incoming or outgoing calls.   |
| In-service                     | The trunk is activated and can be used for both incoming and outgoing calls.  |
| Disconnect (ready-for-service) | The trunk is in an activated state but can only be used for an incoming call. |

If the DS1 Interface circuit pack or media module is out of service, every trunk on the DS1 Interface circuit pack or media module is placed into the out-of-service state and a Warning alarm is raised.

---

## Error log entries and recommended actions

**Table 262: TIE-DS1 Error Log Entries 1 of 2**

| Error Type | Aux Data                         | Associated Test                      | Alarm Level | On/Off Board | Recommended Action                               |
|------------|----------------------------------|--------------------------------------|-------------|--------------|--------------------------------------------------|
| 0 (a)      | 0                                | Any                                  | Any         | Any          | <code>test trunk grp#/mem#</code>                |
| 1 (b)      | 57476<br>57477<br>57485<br>57487 |                                      |             |              |                                                  |
| 15 (c)     | Any                              | Port Audit and Update (#36)          |             |              |                                                  |

|            |          |                              |                         |              | <b>2 of 2</b>                                        |

1. For TN767B vintage 8 or 9 circuit packs, a failure of Test #136 causes a subsequent failure of Test #7. Test #136 is part of the short sequence and generates off-board alarms. Test #7 is part of the long sequence and generates on-board alarms. Before entering busyout, release, reset or test board long commands, check the vintage number of the circuit pack with `list configuration board location`. If it is TN767B vintage 8 or 9, do not use the above commands until you ensure sure that Test #136 passes via test board short. Otherwise, extraneous on-board alarms may be generated.
2. Major or Minor alarms on this MO may have been downgraded to Warning based on the values in `set options`.

## Notes:

- a. **Error Type 0:** run the short test sequence first. If every test passes, run the long test sequence. Refer to each appropriate test's description, and follow its recommended procedures.

- b. **Error Type 1:** the DS1 Interface circuit pack or media module detects a hardware error on the DS1 tie trunk. This error can be caused by incompatible translations. Make sure the parameters administered on the DS1 circuit pack or media module form match those administered on the far-end switch. See *Administering Avaya Aura™ Communication Manager* for details.

The Aux Data field indicates the following hardware Error Types:

|       |                                                                                                                                                                |
|-------|----------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 57476 | On-hook before wink                                                                                                                                            |
| 57477 | On-hook before ready to receive digits                                                                                                                         |
| 57485 | Wink too short for valid signal                                                                                                                                |
| 57487 | The timer expired while waiting for an off-hook signal from the far end as a response at end-of-digits dialing. Check the far-end switch for related problems. |

If every administration parameter between the switch and the far end match and these errors continue to recur, follow normal escalation procedures.

- c. **Error Type 15:** this is a software audit error that does not indicate any hardware malfunction. Run the short test sequence, and investigate associated errors (if any).
- d. **Error Type 18:** the DS1 tie trunk has been busied out with `busyout trunk grp#/mem#`. No calls can be made on this trunk except for the Facility Access Test call. See *Administering Avaya Aura™ Communication Manager*.
- e. **Error Type 19:** the far end may be out-of-service, or the Electronic Tandem Network may be busied out.
- f. **Error Type 130:** the circuit pack or media module has been removed or has been insane for more than 11 minutes. To clear the error, reinsert or replace the circuit pack or media module.
- g. **Error Type 257:** the DS1 Interface circuit pack or media module detects a hardware error on the DS1 tie trunk. The trunk cot communicate with the far end because it is unable to interpret digits sent from the far-end switch. The Aux Data field indicates the following:

|       |                                                     |
|-------|-----------------------------------------------------|
| 57473 | The rotary dial rate is below 8 pulses per second.  |
| 57474 | The rotary dial rate is above 12 pulses per second. |

Check with the far-end switch or operating company for proper trunk connection.

- h. **Error Type 513:** the DS1 Interface circuit pack or media module detects a hardware error on the DS1 tie trunk. The trunk is in-service/active and waiting for an “on-hook” from the far-end switch. No calls can be routed over the trunk while it is in this state. Aux Data 57392 indicates no external release on PBX disconnect. Check with the far-end switch or operating company for proper trunk connection.

- i. **Error Type 769:** the DS1 Interface circuit pack or media module detects a hardware error on the DS1 tie trunk. This error usually occurs after an occurrence of Error Type 513. The trunk has received the belated “on-hook” that it has been waiting for from the far-end switch. The trunk is restored to in-service/idle and can be used for calls. Aux Data 57393 indicates delayed external release on PBX disconnect. This error can be ignored.
- j. **Error Type 1793:** the DS1 Interface circuit pack or media module is out-of-service. See the appropriate [DS1-BD \(DS1 Interface Circuit Pack\)](#), [UDS1-BD \(UDS1 Interface Circuit Pack\)](#), or [MG-DS1 \(DS1 Interface Media Module\)](#) documentation for details.
- k. **Error Type 2305:** reorder message. The trunk could not be seized. This error causes the Trunk Seizure test (#136) to run and is only a problem if the Seizure test fails (in which case Error Type 1025 also appears). In this case, the trunk may be put in “Ready-for-Service” state (shown as “disconnected” by the status command), which allows only incoming calls. Run the Trunk Seizure test (#136) and follow its procedures.
- l. **Error Type 2562:** retry Failure error. This error is logged only. It is not a hardware failure and hence does not start any testing or generate any alarms. This error comes from call processing and is generated when a second attempt (retry) to seize an outgoing trunk fails.
- m. **Error Type 2817:** glare error. This error is logged only. It is not a hardware failure and hence does not start any testing or generate any alarms. This error is the result of a simultaneous seizure of a 2-way trunk from both the near and the far ends. Attempt to place the call again. If the error persists, execute the DS1 Tie Trunk Seizure test (#136) and follow its procedures.
- n. **Error Type 3840:** Port Audit and Update test (#36) failed due to an internal system error. Enter **status trunk**, and verify the status of the trunk. If the trunk is out-of-service, enter **release trunk** to put it back to in-service. Retry the test command.

---

## Demand test descriptions and error codes

Investigate tests in the order presented. By clearing errors associated with the first test, errors generated from other tests may also be cleared. Click on the link to see the full description of the test, error codes, and recommended actions.

| Order of Investigation                            | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|---------------------------------------------------|---------------------|--------------------|-------------------|
| <a href="#">NPE Crosstalk Test (#6)</a>           |                     | X                  | ND                |
| <a href="#">Conference Circuit Test (#7)</a>      |                     | X                  | ND                |
| <a href="#">DS1 Tie Trunk Seizure Test (#136)</a> | X                   | X                  | ND                |
| <a href="#">Port Audit And Update Test (#36)</a>  | X                   | X                  | ND                |

1. D = Destructive; ND = Nondestructive

### Note:

For TN767B vintage 8 or 9 circuit packs, a failure of Test #136 causes a subsequent failure of Test #7. Test #136 is part of the short sequence and generates off-board alarms Test #7 is part of the long sequence and generates on-board alarms. Before entering **busyout**, **release**, **reset** or **test board location long** commands, check the vintage number of the circuit pack with **list configuration board location**. If it is TN767B vintage 8 or 9, do not use the above commands until first making sure that Test #136 passes using **test board location**. Otherwise, extraneous on-board alarms may be generated.

## TIE-TRK (Analog Tie Trunk)

| MO Name In Log | Alarm Level             | Initial Command to Run <sup>1</sup> | Full Name of MO  |
|----------------|-------------------------|-------------------------------------|------------------|
| TIE-TRK        | MAJ <sup>2</sup><br>MIN | <code>test port location 1</code>   | Analog Tie Trunk |
|                | WRN                     | <code>test port location</code>     |                  |

1. If ATMS testing is enabled, check the error log for ATMS errors 3840 and 3841. If the error log indicates that measurements exceeded acceptable thresholds, and no other trouble is found with `test trunk`, run the ATMS test call with `test analog-testcall port location full`.
2. A Major alarm on a trunk indicates that alarms on these trunks are not downgraded by `set options` and that at least 75 percent of the trunks in this trunk group are alarmed.

This alarm does not apply to TN497.

### Note:

Many trunk problems are caused by incorrect settings of parameters on the trunk group administration screen. Settings must be compatible with the local environment and with parameter settings on the far end. Refer to *Administering Avaya Aura™ Communication Manager*. Refer to your Avaya representative for the correct settings for administrable timers and other parameters on a country-by-country basis.

The following circuit packs, including every suffix such as TN760D, support analog tie trunks:

**Table 263: Analog Tie Trunk Circuit Packs**

| Code   | Trunk Type | Signaling Leads           |
|--------|------------|---------------------------|
| TN760  | 4-wire     | E&M                       |
| TN437  | 4-wire     | E&M                       |
| TN439  | 2-wire     | A&B (2-way circuits only) |
| TN458  | 4-wire     | E&M                       |
| TN497  | 2-wire     | A&B                       |
| TN2140 | 4-wire     | E&M                       |

Each tie trunk circuit pack occupies a port circuit pack slot and contains 4 port circuits. Each port circuit supports 1 analog tie trunk used to connect the switch to another PBX across 1- or 2-way dedicated circuits (see preceding list).

A tie trunk port can also be administered as an access endpoint which is a non-signaling channel with a voice-grade data bandwidth. Tie trunk maintenance employs up to 6 tests, depending on the hardware involved, to monitor the operating condition of the trunk and its connections. The port must be idle for these tests to run. If an incoming call seizes the port while a test is in progress, the test aborts and the call proceeds (except for TN497).

The test are as follows:

1. NPE Crosstalk Test—Verifies the switch connection operation of the circuit pack. It verifies that the trunk circuitry talks only on the selected time slot on the TDM Bus and that it never crosses over to time slots reserved for other connections.
2. Looparound and Conference Circuit Test—Verifies the transmission operation of the circuit pack. It verifies that signals are transmitted to and from each port (Looparound within the port), and it tests the conference capabilities of all ports.

This test may fail due to noise induced by adjacent electric power lines. Customers having this problem should resolve it with their local power company. To temporarily alleviate the alarm caused by the failure of this test, the test may be disabled from trunk administration test field.

3. Several seizure tests, including the following:
  - 1 Tie Trunk Seizure Test verifies the seizure capabilities of the circuit pack. For the TN2140B circuit pack, this test activates the M lead and checks for a response from the distant end within 10 seconds. This test ABORTS on trunk ports administered as access endpoints.
  - 1 Seizure Test (for TN497 circuit packs only)—Verifies the seizure capabilities of the circuit pack. This test seizes the trunk and outpulses a “pause.” The port reports the result of the seizure attempt uplink. The test can be disabled via Trunk Group Administration.
4. EPF, M, and E Lead Test ABORTS on trunk ports administered as access endpoints. This test consists of two parts:
  - 1 E lead test—Checks for the proper activation and deactivation of the port’s E lead.
  - 1 M lead test—Checks the M lead EPF current flow. The results of this test allow for distinguishing between circuit pack and external facility failures.
5. Port Audit Update Test (Audit & Update Test for the TN497 circuit pack)—Sends non-disruptive administrative updates to the circuit pack with no expected response. The test updates the translation information on individual ports of the Tie Trunk. Except for the TN497 circuit pack, these updates include:
  - 1 Immediate, automatic, wink start, or delay dial; for the TN2140B, continuous-seize-ack
  - 1 For the TN2140B, continuous or discontinuous.
  - 1 Rotary or DTMF senderization in or out
  - 1 Disconnect timing
  - 1 DMTF time slot

Additional inline testing is performed whenever a call is in progress, logging errors that occur during operation. You can reproduce these types of errors by making a call over the trunk and then checking the Error Log.

By making translation and cross-connect changes, circuit packs (except for TN497) can be configured for back-to-back testing, also known as connectivity testing. Port operation is tested by connecting two tie trunk ports together in either E&M or simplex modes. See the section [Analog tie trunk back-to-back testing](#) in *Maintenance Procedures (03-300432)*.

## Error log entries and recommended actions

Table 264: TIE-TRK Error Log Entries 1 of 2

| Error Type | Aux Data | Associated Test                      | Alarm Level                    | On/Off Board | Recommended Action                   |
|------------|----------|--------------------------------------|--------------------------------|--------------|--------------------------------------|
| 0 (a)      | 0        | Any                                  | Any                            | Any          | <code>test port location</code>      |
| 1 (b)      | 16384    |                                      | WRN                            | OFF          |                                      |
| 1 (c)      | 57476    |                                      | WRN                            | OFF          |                                      |
| 1 (d)      | 57477    |                                      | WRN                            | OFF          |                                      |
| 1 (e)      | 57483    |                                      | WRN                            | OFF          |                                      |

|            |                |                                                     |                                |              | <b>2 of 2</b>                            |

1. Minor alarms on this MO may be downgraded to Warning based on the values used in `set options`. If the MINOR alarm is not downgraded, the MINOR alarm is upgraded to a MAJOR alarm if 75% of the trunks in this trunk group are alarmed. These errors, if applicable, always log a MINOR alarm for TN439 and TN497.

Notes:

- a. **Error Type 0:** run the short test sequence first. If every test passes, run the long test sequence. Refer to each appropriate test's description, and follow its recommended procedures.

- b. **Error Type 1:** digit time-out. This occurs when the far-end PBX began transmitting digits too late (10 seconds) after receiving the signal indicating ready to receive digits (if any). This can occur on an incoming immediate, wink, or delay dial line. Check the far-end PBX to ensure a translation match at both ends. This error does not apply to TN497.
- c. **Error Type 1:** rotary dial before wink. This occurs when the far-end PBX starts dialing before the PBX sends the wink on a wink-start or delay-dial trunk. Check the far-end PBX to ensure a translation match at both ends. This error does not apply to TN497.
- d. **Error Type 1:** rotary dial too early. This occurs when the far-end PBX starts dialing too soon (about 50ms) after seizure on a wink start or delay dial line. Check the far-end PBX to ensure a translation match at both ends. This error does not apply to TN497.
- e. **Error Type 1:** on-hook before wink. This occurs when the far end goes on-hook before a wink. Check the far-end PBX to ensure a translation match at both ends. This error applies only to TN439.
- f. **Error Type 1:** on an outgoing wink-start or delay-dial trunk, the wink time was too short (less than 80ms) for a valid signal. Check the far-end PBX to ensure a translation match at both ends. This error does not apply to TN497.
- g. **Error Type 15:** this is a software audit error that does not indicate any hardware malfunction. Run the short test sequence, and investigate associated errors (if any).
- h. **Error Type 18:** this indicates that the trunk in question has been busied-out by maintenance personnel.
- i. **Error Type 130:** the circuit pack has been removed or has been insane for more than 11 minutes. To clear the error, reinsert or replace the circuit pack. TN439 does not alarm this error. This error does not apply to TN497.
- j. **Error Type 257:** the rotary dial rate was too slow — less than 8 pulses per second. Check the far-end PBX to ensure a translation match at both ends.
- k. **Error Type 257:** the rotary dial rate was too fast — above 12 pulses per second. Check the far-end PBX to ensure a translation match at both ends.
- l. **Error Type 257:** the time between digits was too short (less than 300ms). Check the far-end PBX to ensure a translation match at both ends.
- m. **Error Types 513, 769, 1281:** these errors do not apply to TN439 and TN497.
- n. **Error Type 1025:** this indicates that the trunk is still seized with an incoming call. The far-end PBX is not releasing the trunk after the call was dropped. Check the far-end PBX for problems.

Once the trunk is released from the call, the severity of this problem is decreased. If Error Type 1025 does not appear again, this means that the problem has been corrected. Verify that Error Type 1025 does not reappear in the Error Log.

- o. **Error Type 2305:** reorder message. The trunk could not be seized. This error causes the Tie Trunk Seizure test (#73) to run and is considered a problem only if that test fails, logging error 1793. In this case, the trunk may be placed in the ready-for-service state, allowing only incoming calls. This service state shows up as **disconnected** on the Trunk Status screen. Run the [Tie Trunk Seizure Test \(#73\)](#), and follow recommended procedures.

TN439 logs Aux Data 57424 or 50944. Other circuit packs log 50944. This error is associated with [Tie Trunk Dial Test \(#747\)](#) for TN439, [Tie Trunk Seizure Test \(#73\)](#) for TN497, and no test for the others.

- p. **Error Type 2561, 2817:** these errors apply only to TN497.
- q. **Error Type 2562:** retry failure error. This error is logged only. It is not a hardware failure and hence does not start any testing or generate any alarms. This error comes from call processing and is generated when a second attempt (retry) to seize an outgoing trunk fails.
- r. **Error Type 2817:** glare error. This error is logged only. It is not a hardware failure and hence does not start any testing or generate any alarms. This error is the result of a simultaneous seizure of a 2-way trunk from both the near and the far ends. Attempt to place the call again. If the error persists, execute the [Tie Trunk Seizure Test \(#73\)](#), and follow its outlined procedures.
- s. **Error Type 3840:** indicates measurements were in the marginal range. Use `list testcall detail` to examine the specific transmission parameters which are out of spec, and investigate the trunk for that kind of noise. If the noise is acceptable, then the ATMS thresholds administered on page 4 of the trunk group screen should be changed.

**Error Type 3841:** indicates that test calls made by the Automatic Transmission Measurement System (ATMS) returned measurements in the unacceptable range.

---

## Demand test descriptions and error codes

Investigate tests in the order presented. By clearing errors associated with the first test, errors generated from other tests may also be cleared. Click on the link to see the full description of the test, error codes, and recommended actions.

| Order of Investigation                               | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|------------------------------------------------------|---------------------|--------------------|-------------------|
| <a href="#">NPE Crosstalk Test (#6)</a>              |                     | X                  | ND                |
| <a href="#">Looparound and Conference Test (#33)</a> |                     | X                  | ND                |
| <a href="#">Tie Trunk Seizure Test (#73)</a>         | X                   | X                  | ND                |
| <a href="#">Tie Trunk Dial Test (#747)</a>           | X                   | X                  | ND                |
|                                                      |                     |                    | <b>1 of 2</b>     |

| Order of Investigation                                             | Short Test Sequence | Long Test Sequence | D/ND <sup>1</sup> |
|--------------------------------------------------------------------|---------------------|--------------------|-------------------|
| <a href="#">Tie Trunk EPF Test (#74)</a>                           | X                   | X                  | ND                |
| <a href="#">Port Audit And Update Test (#36)</a>                   | X                   | X                  | ND                |
| <a href="#">Automatic Transmission Test (#844-848)<sup>2</sup></a> |                     |                    | ND                |
|                                                                    |                     |                    | <b>2 of 2</b>     |

1. D = Destructive, ND = Nondestructive

2. ATMS tests are not part of either sequence. They are run either on demand with `test analog-testcall`, or by the ATMS schedule.

## TIME-DAY (Time of Day)

| MO Name in Log | Alarm Level | Initial Command to Run | Full Name of MO |
|----------------|-------------|------------------------|-----------------|
| TIME-DAY       | MIN         | <code>set time</code>  | Time of Day     |

The time of day contains the current year, month, day of the week, day of the month, hour, minute, and second. The Time of Day MO monitors the time-of-day clock, and raises an alarm if the time-of-day clock is not set or cannot be read by the software. If the time-of-day clock is not set or cannot be read by the software, many features such as Time-of-Day Routing, CDR, ISDN Call-by-Call, and duplication, are inoperative or incorrect. Use `set time` to set the time-of-day clock when the system is initially powered up.

Use `display time` to read the time-of-day clock. Use `set time` to set the time-of-day clock. The time-of-day clock has a backup battery to save the time of day during power failures.

There are no demand tests associated with TIME-DAY.

---

## Error log entries and recommended actions

Table 265: TIME-DAY Error Log Entries

| Error Type | Aux Data | Associated Test | Alarm Level | On/Off Board | Recommended Action        |
|------------|----------|-----------------|-------------|--------------|---------------------------|
| 0          | 0        | Any             | Any         | Any          | <code>display time</code> |
| 247 (a)    | 0        |                 | MIN         | OFF          | <code>set time</code>     |

Note:

- a. **Error Type 247:** software cannot read the time-of-day clock. During this condition, every time stamp in the Alarm Log entry, Error Log entry, and Software Error Log entry is potentially inaccurate. In addition, any features that are sensitive to the time of day (such as SMDR, Time-of-Day Routing, ISDN Call-by-Call) will not function correctly.

To resolve the alarm:

1. Use `set time` to set the time of day.
2. Use `display time` to display the time of day. If the time of day is displayed correctly, wait 15 minutes and verify that the alarm is retired.

## TONE-BD (Tone-Clock Circuit Pack)

| MO Name | Alarm Level | Initial Command to Run                   | Full Name of MO    |
|---------|-------------|------------------------------------------|--------------------|
| TONE-BD | MAJ<br>MIN  | <code>test tone-clock location</code>    | Tone-Clock circuit |
|         | WRN         | <code>release tone-clock location</code> |                    |

The TONE-BD MO supports PNs in a system using either a TN2312 IP Server Interface (IPSI) circuit pack, or non-IPSI EPNs equipped with Tone Clock circuit packs.

For IPSI-equipped EPNs, the TONE-BD MO consists of a module located on the IPSI circuit pack and provides tone generation, tone detection, call classification, clock generation, and synchronization. It replaces the TN2182B Tone-Clock board and is inserted into each PN's Tone-Clock slot. For non-IPSI EPNs, the TN2182B Tone-Clock circuit pack provides the functions.

The TN2312 IPSI circuit pack for a PN equipped with IPSIs, or the Tone-Clock circuit pack for a non-IPSI PN, contains two independent components:

- 1 Tone Generator that provides every tone needed by the system
- 1 Clock that generates the system clocks for both the Time Division Multiplex (TDM) bus and the packet (LAN) bus

It also aids in monitoring and selecting internal synchronization references.

When resolving an IPSI or Tone-Clock circuit pack's errors/alarms, the following sections should also be consulted:

- 1 For non-IPSI EPNs, use the `set tone-clock location` command to establish the tone and synchronization resources for the system.
- 1 For IPSI EPNs, use `set ipserver-interface` to establish the tone and synchronization resources for the system.
- 1 TONE-PT (Tone Generator)
- 1 TDM-CLK (TDM Bus Clock)
- 1 SYNC (Synchronization)
- 1 ETR-PT
- 1 PKT-INT (IPSI only)

The TN2182 is a combined Tone-Clock/Detector circuit pack, providing Tone-Clock functionality to a non-IPSI PN. It provides 8 Enhanced Tone Receiver (ETR) ports. Each of these ports combines the individual capabilities of a DTMR-PT, a GPTD-PT, and a CLAS-PT. Thus, each TN2182 port offers any tone-detection function previously provided by a TN748, TN420, or TN744 Tone Detector board.

The TN2182 also provides either Mu-law or A-law tone detection.

Since the TN2182 also provides Tone-Clock function for non IPSI port networks, only one (or two if your system is duplicated) TN2182 circuit packs may reside in a PN. If more tone-detection resources are needed, the additional resources must be provided by TN748, TN420, or TN744 circuit packs.

---

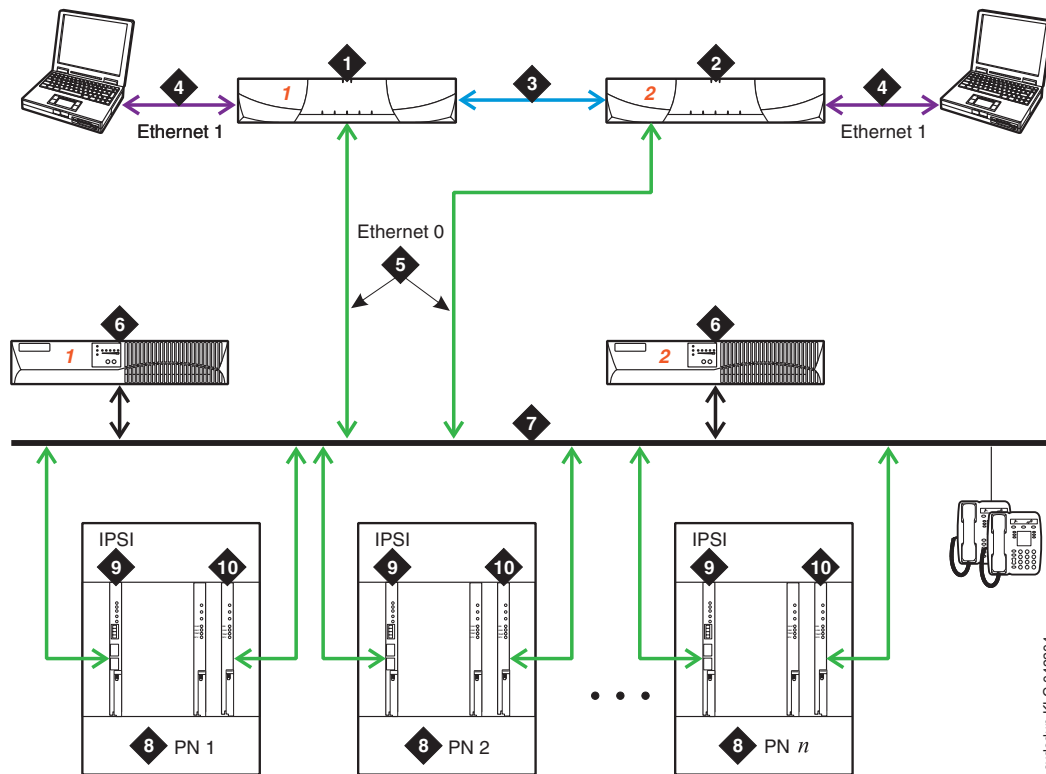

## Tone-Clock and the Reliability Configuration

---

### **S8700-series IP-PNC**

A Tone Clock circuit resides on each IPSI board. For increased reliability, there is a duplicated server, one in active mode and one on standby. However, there is only one control network and one IPSI per port network as shown in [Figure 88: S8700 IP-PNC Duplex Reliability Configuration](#). Therefore there is only one Tone Clock circuit per port network.

Figure 88: S8700 IP-PNC Duplex Reliability Configuration

cvsdup KLC 042204

## Figure notes:

1. S8700 Server 1 - two are always present, one in a active mode and the other on standby.
2. S8700 Server 2 - two are always present, one in a active mode and the other on standby.
3. Duplication Interface - The Ethernet connection between the two S8700 Servers.
4. Services Interface - The S8700 Servers dedicated Ethernet connection to a laptop. This link is active only during on-site administration or maintenance and the services interface can link to the non-active server through a telnet session.
5. Connection from the Servers to the Ethernet Switch.
6. Ethernet Switch - A device that provides for port multiplication by having more than one network segment. In an IP-PNC environment, the Ethernet Switch should support 802.1 IP/Q, VLAN and 10/100 mbps.
7. UPS units - two required.
8. Port Network - optional configuration of Media Gateways that provides increased switch capacity.
9. IPSI - provides transport of CCMS messages over IP allowing the S8700 Server to communicate with the Port Networks.
10. Customer LAN

---

## S8700-series Fiber-PNC

In IPSI connected port networks, the Tone Clock circuit is found on the IPSI circuit pack. In non IPSI connected port networks, there is a Tone Clock circuit pack. The following sections describe the relationship between the various reliability options and the IPSIs or Tone Clock circuits.

Three items can be duplicated: server, IPSI, and PNC. Note that duplicated control networks and duplicated IPSIs go together; when the IPSIs are duplicated, the control networks must be duplicated. While all items can be independently duplicated, the combination of duplicated bearer networks (PNCs) and unduplicated control networks is not allowed. See [Table 266: S8700 Fiber-PNC Reliability Configurations](#).

**Table 266: S8700 Fiber-PNC Reliability Configurations**

| <b>Configuration</b> | <b>Server</b> | <b>Control Network and IPSI</b> | <b>Bearer Network</b> |
|----------------------|---------------|---------------------------------|-----------------------|
| Duplex Reliability   | Duplicated    | Unduplicated                    | Unduplicated          |
| High Reliability     | Duplicated    | Duplicated                      | Unduplicated          |
| Critical Reliability | Duplicated    | Duplicated                      | Duplicated            |

### Duplex-Reliability Configuration

The duplex-reliability configuration shown in [Figure 89: Duplex-Reliability Configuration](#) has a duplicated server, an unduplicated control network, unduplicated IPSIs in the IPSI connected port networks, and an unduplicated bearer network. Therefore the Tone Clock is not duplicated in the IPSI connected port network. In the non IPSI connected port network, the Tone Clock boards are also not duplicated.

---

**Figure 89: Duplex-Reliability Configuration**

---

## Standard Reliability

Systems with the standard-reliability option (no duplication options) have one Tone-Clock circuit pack in each port network. For the first Port Network of a cabinet this is in the A carrier. Cabinets containing a second EPN will also have a Tone-Clock circuit pack in the E carrier. This Tone-Clock circuit pack generates clocks and provides system tones for every carrier of the port network it resides in.

## High Reliability

**S8700-series Fiber-PNC:** The high-reliability configuration shown in [Figure 90: High-Reliability Configuration](#) has a duplicated server, a duplicated control network, and duplicated IPSIs in the IPSI connected port networks. With this configuration, every IPSI connected PN must have duplicated IPSIs. The control network is duplicated so that a single fault in the control network, such as a bad Ethernet switch, won't bring the whole system down. The non IPSI connected port networks have unduplicated Tone-Clock boards.

An EPN's Tone-Clock circuit pack configuration is the same as for the standard-reliability option. Each PN's Tone-Clock circuit is active for both tones and clock signals for its port network.

---

**Figure 90: High-Reliability Configuration**

---

Systems with the High Reliability Option have one Tone-Clock circuit pack in each Port Network control carrier, A and B. One Tone-Clock circuit pack will be actively generating system clock signals for Port Network components, while the other will be in standby mode, ready to take over in the event of a Tone-Clock interchange. Similarly, one Tone-Clock circuit pack will be actively providing system tones for the Port Network, while the other will be in standby mode. Normally, the same Tone-Clock circuit pack will be active for both tones and clock signals, but these responsibilities may be divided if neither circuit pack is able to perform both functions. The `status port-network` command indicates which Tone-Clock circuit pack is actively performing each function.

For systems using the TN2182 Tone-Clock-Detector circuit pack, tone generation and clock generation behaves the same as other clock boards with one being active and one being standby. But the tone detector ports (ETR-PTs) of the TN2182 are always considered available and in-service regardless of the active/standby state of the tones or clock for a specific circuit pack.

EPN Tone-Clock circuit pack configuration is the same as for the Standard Reliability Option. Each EPN Tone-Clock circuit pack will be active for both tones and clock signals for its port network.

## Critical Reliability

**S8700-series Fiber-PNC:** The critical-reliability configuration shown in [Figure 91](#) has full duplication of the following options: servers, control networks, IPSIs and PNCs (bearer networks). As with the high-reliability configuration, this configuration also requires that IPSI connected port networks have duplicated IPSIs. This configuration also requires that the non IPSI connected port networks have duplicated Tone-Clock boards (either TN2182 or TN780).

**Figure 91: Critical-Reliability Configuration**

## Tone-Clock Interchange Strategy

There are three types of Tone-Clock interchanges:

- 1 Autonomous interchanges initiated as a part of maintenance software strategy for the Tone-Clock or IPSI circuit packs.
- 1 Manual interchanges initiated by `set tone-clock` or `set ipserver-interface`.
- 1 Firmware-initiated Tone-Clock interchanges

## Software Initiated Tone-Clock Interchanges

Tone-Clock interchanges may be initiated by software in two ways:

1. A scheduled Tone-Clock or IPSI circuit pack interchange occurs according to the parameters set by `change system-parameters maintenance`. This parameter can be disabled or set to run weekly, the default is for it to occur daily, at a time specified in the system-parameters list for scheduled maintenance to begin. This interchange will be blocked, if the non-preferred Tone-Clock or IPSI circuit pack in a PN has been selected with `set tone-clock` or `set ipserver-interface`. Also if the standby Tone-Clock or IPSI has been set to the busyout state, or if the clock generation capability is known to be impaired. When this scheduled interchange occurs, the standby Tone-Clock or IPSI circuit pack becomes active for twenty seconds to test its ability to generate clock signals. For IPSI scheduled interchanges, the other IPSI modules located on the IPSI circuit pack, i.e. the Packet interface and Archangel are also tested. After testing the IPSI is returned to standby mode.
2. **For non IPSI Port Networks**, unscheduled interchanges occur when on-board Tone-Clock circuit-pack maintenance, or ongoing switch maintenance test of the TONE-BD, TONE-PT or the TDM-CLK uncover failures serious enough to raise a MAJOR or MINOR alarm against the active Tone-Clock circuit pack.

**For IPSI Port Networks**, unscheduled IPSI/Tone-Clock interchanges may occur any time as a part of an unscheduled IPSI interchange. The IPSI interchange may be the result of Tone-Clock, PKT-INT, or EAL faults.

### International Settings

**Note:**

The following information is for **non IPSI** port networks.

The TN780 Tone-Clock circuit pack uses three firmware configuration parameters for international support. The following two are automatically set by the software load for the targeted country:

- 1 The circuit pack's country-code (USA, ITALY, AUSTRALIA, etc.)
- 1 The circuit pack's companding mode (mu-Law or A-Law)

The third configuration parameter is used only for Italy (country code: ITALY), and selects whether *new* versus *old* ISPT (Istituto Superiore Poste Telegrafi) tones will be used for dial and confirmation tones. Values for dial confirmation tone can be set independently on the `change tone-generation` form. Whenever such changes are made, the effects are immediately enforced on all TN780 Tone-Clock circuit packs without disrupting tone or timing services.

| Tone         | Default    | Old ISPT Value |
|--------------|------------|----------------|
| Dial         | Continuous | Cadenced       |
| Confirmation | Cadenced   | Continuous     |

In addition the TN780 allows customization of up to six system tones in order to meet specific country needs. These changes are made using the **change system-parameters country-options** form.

The TN2182 allows the same International changes as the TN780 but allows the customization of up to 24 system tones in order to meet specific country needs. These changes are made using the **change tone-generation** form.

## Manual Tone-Clock Interchange

In an EPN with duplicated Tone-Clock or IPSI circuit packs, one circuit pack is always preferred over the other. For the first port network in a cabinet, this is the Tone-Clock or IPSI circuit pack in carrier **A**. If a second port network is configured in a cabinet, its preferred Tone-Clock or IPSI circuit pack is located in carrier **E**. The intention is that if the preferred Tone-Clock or IPSI circuit pack has been replaced or repaired, the system will make it active by interchanging to it as soon as possible.

In a Port Network (PN) with more than one Tone-Clock circuit pack, the intention is to assure that the one considered most healthy is active at any given time. *This is independent of the server duplication strategy*, in the sense that the active Tone-Clock circuit pack need not change with an interchange of carriers. Rather, except for the effect of the manual intervention discussed earlier, Tone-Clock interchanges occur only as a result of changes in the health of Tone-Clock circuit packs, as perceived by maintenance software. When both Tone-Clock circuit packs are equally healthy, no preference is given to one over the other, regardless of which carrier is active.

It is possible to manually control Tone-Clock interchanges in three ways.

1. The standby Tone-Clock circuit pack may be made unavailable for most purposes by using **busyout tone-clock location**. Such a Tone-Clock may not be selected with console commands, nor with normal maintenance software activities, until it has been made available again with **restore tone-clock location**.

### Note:

**busyout tone-clock** is not allowed for active Tone-Clock circuit packs.

2. The processor lock switches may be used to force a particular SPE to be active. *This method overrides all other Tone-Clock interchange controls*. If there is a Tone-Clock circuit pack in the same carrier as the active SPE, it will become active, regardless of its health. If the Tone-Clock circuit pack in the selected SPE was in the *busyout* state (see item 1 above), it will automatically be released and made active. While the lock switches are set for a particular carrier, *no manual intervention or software error detection* will cause an interchange of Tone-Clocks; the Tone-Clock circuit pack in the standby SPE carrier can never become active. If there is no Tone-Clock circuit pack in the selected SPE at the time the switches are set, but one is later installed, the system will interchange to it regardless of its health. If the Tone-Clock circuit pack is removed from an SPE while the switches are set, *no interchange will occur*, the system will have no active tone-clock. When the lock switches are restored to the neutral position, a tone clock interchange will occur only if the standby Tone-Clock circuit pack is healthier than the active one.

3. A particular Tone-Clock circuit pack can be made active by entering `set tone-clock location [override]`. If the Tone-Clock to be made active is less healthy than the currently active one, no interchange will occur unless the `override` option is specified; without it a message will inform the user that it is required.

Once a Tone-Clock circuit pack is made active by the `set tone-clock location` command, it will stay active until either the `set tone-clock location` command is entered again to make the other circuit pack active, or until a fault occurs in the active Tone-Clock circuit pack, which causes the system to interchange Tone-Clocks.

---

## Firmware Instigated Tone-Clock Interchanges

Firmware-initiated Tone-Clock interchanges occur when the auto clock switching option is enabled, and the TN2312 IPSI circuit pack firmware detects a loss of clock or clock errors. After detecting a loss of clock/clock errors, and rather than waiting for system software to request a switch, the IPSI firmware will automatically switch the clock (when auto clock switching is enabled). The auto clock switching option is disabled during system restarts.

**Note:**

The auto clock switching option is required by the IPSI circuit pack since the EAL connection to the PKT-INT (one of the IPSI circuit packs many functions) is over the server packet bus which must have a good clock for proper operation.

## Clock Synchronization

**Note:**

Stratum-3 clocking is not available for a port network supported by a TN2312 (IPSI) circuit pack, or a port network where the Tone-Clock function is supplied by a TN2182.

This section discusses synchronization with a Stratum-3 or -4 clocking device.

## Stratum 3

Since the clock module on the TN2312 does not support synchronization with an external Stratum-3 clocking device, you may provide Stratum-3 clocking for a S8700 Server system by using the TN780 Tone-Clock circuit pack in a non-IPSI connected port network. To bring in the external Stratum-3 clocking signals into the TN780, a processor carrier is needed. This new PN control carrier will replace the processor carrier in the old Processor Port Network (PPN) converted to PN 1. The Stratum-3 clocking must come into Port Network #1 because the S8700 Fiber-PNC software has the Stratum-3 clocking hard-coded to this port network.

## Stratum 4

With S8700 Fiber-PNC, PN 1 may or may not exist and thus not be relied on as the backup synchronization source. If a S8700 Fiber-PNC system does not have an administered synchronization source, it uses the first PN that comes up as its source. If the designated master and secondary synchronization sources fail, the system uses any other PN as its source. No preference is given to PN 1.

---

---

## Replacing the IPSI or Tone-Clock Circuit Pack

Replacing a TN2312 IPSI circuit pack or Tone-Clock circuit pack is a service-disrupting procedure in a PN with a single Tone-Clock, because the IPSI or Tone-Clock circuit pack is always needed to generate clocks for its PN. When the circuit pack is removed, every call is immediately dropped, the PN enters emergency transfer within one minute, and no calls can be set up from or to that PN.

However, if the Processor Port Network (PPN) Tone-Clock is removed for replacement in a Standard Reliability Option system, the System Emergency Transfer feature is activated within milliseconds, and the entire system is disrupted; no calls can be placed, and existing calls are dropped.

However, if the Processor Port Network (PPN) Tone-Clock is removed for replacement in a standard-reliability system, the System Emergency Transfer feature is activated within milliseconds, and the entire system is disrupted; no calls can be placed, and existing calls are dropped.

When replacing an IPSI or Tone-Clock circuit pack, always be sure to replace it with the appropriate IPSI or Tone-Clock circuit pack for the system.

The following circuit-pack code(s) are supported:

|                                               |                                                                                                                                                                                                                                                                                                                                                                                                        |
|-----------------------------------------------|--------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| <b>S8700-series<br/>Fiber-PNC:<br/>TN768</b>  | This is a general-purpose Tone-Clock circuit pack for EPNs. It can be used in every situation, except as the Master Tone-Clock circuit pack when a Stratum-3 clock is administered.                                                                                                                                                                                                                    |
| <b>S8700-series<br/>Fiber-PNC:<br/>TN780</b>  | The Stratum-3 clock feature requires the use of this circuit pack code in PN 1. The Stratum-3 clock will operate only with this code as the Master Tone-Clock circuit pack. The TN780 circuit pack is upward compatible with the TN768 code, and can be used in any place a TN768 would be allowed. The TN780 is used in many countries outside the U.S. where the TN768 does not provide local tones. |
| <b>S8700-series<br/>Fiber-PNC:<br/>TN2182</b> | This Tone-Clock-Detector may be used anywhere a TN768 or TN780 is used, with the exception of configurations requiring Stratum-3 clock. The TN2182 may be used in all country configurations.                                                                                                                                                                                                          |
| TN2312                                        | The TN2312 IPSI circuit pack supplies Tone-Clock functionality for S8700 systems.                                                                                                                                                                                                                                                                                                                      |

---

## Port Networks with a Single Tone-Clock Circuit Pack

This procedure is **destructive**.

1. Pull out the defective IPSI or Tone-Clock circuit pack. This will remove the clocks and cause the system to activate emergency measures. If this is an IPSI supported port network, use `busyout ipserver-interface`:
  - 1 All calls to and from the PN will drop, and the PN will activate Emergency Transfer within about one minute. But the rest of the system should operate normally.
2. Insert a new IPSI or Tone-Clock circuit pack. The system will detect the return of the clocks and will automatically recover as follows:
  - 1 The system will reset the PN (PN cold restart), and all of the PN's red LEDs will come on and go off within 30 seconds.
3. If the red LEDs come on but do not go off within 30 seconds, pull the circuit pack out and reseal it. If the LEDs perform as expected this time, continue with step 6. Otherwise, there may be a problem with the TDM bus; possibly a bent pin in the IPSI or Tone-Clock circuit pack's slot. Follow the directions in the TDM-BUS maintenance section.
