## BRI XID Test (#628)

This test checks the D-channel connection between the server and an endpoint or adjunct. A D-channel XID frame is sent to the endpoint or adjunct over the point-to-point signaling link. The test passes if the endpoint or adjunct responds with a layer-2 XID-RESPONSE frame.

This test must be administered to not run on the Station Administration screen for ports on a TN2208.

This test runs on [BRI-SET, Various Adjuncts](#).

## BRI Layer 3 Query Test (#629)

The BRI Layer 3 Query Test checks the application layer communications between the switch and the endpoint or adjunct.

For BRI endpoints, an application message containing the appropriate endpoint service state is sent by the switch to the endpoint. The endpoint responds with an acknowledgment to the application message.

This test is not executed for ASAI and Avaya adjuncts from the administration terminal. Rather, a query message is automatically sent by the switch every two minutes. Failure of the switch to receive a response to a query from the adjunct is logged in the Error Log.

This test is run on [BRI-SET, Various Adjuncts](#).

## BRI Set Audits Test (#630)

This is a series of tests that are classified as audits. The switch sends messages to the BRI endpoint to perform the following tests:

- 1 Ringer Audit – This audit verifies that both the switch and the endpoint agree as to the current state of the endpoint’s ringer.
- 1 Lamps Audit – This audit verifies that both the switch and the endpoint agree as to the current state of the endpoint’s lamps.
- 1 Call Activity Audit – This audit verifies that the state of calls is consistent between the switch and the endpoint.

This test is not executed for ASAI or Avaya adjunct because adjuncts do not employ ringers or lamps and do not establish calls on the B-channels associated with the BRI interface.

This test is run on [BRI-SET, Various Adjuncts](#).

|               | PASS        | <p>The switch has successfully executed the BRI station audit test.</p>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
| <b>2 of 2</b> |             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

## Primary Signaling Link Hardware Check (#636)

This test runs on [ATM-SGRP \(ATM Signaling Group\)](#) and [ISDN-SGR \(ISDN-PRI Signaling Group\)](#).

For **ATM-SGRP**, the ATM-SGRP Signaling Group D-channel port depends on the health of the TN230X interface circuit pack on which it resides. This test fails if there are problems with either the ATM-DCH (D-channel port) MO or the TN230X circuit pack. Investigate the ATM TN230X circuit pack [ATM-TRK \(Circuit Emulation Service Circuit Pack\)](#) anytime there are problems with the ATM D-channel port [ATM-DCH \(ATM D-Channel Port\)](#).

For **ISDN-SGR**, the ISDN-PRI Signaling Group D-channel port depends on the health of the TN464 UDS1 Interface circuit pack or DS1 Interface Media Module on which it resides. This test will fail if there are problems with either the ISDN-PRI Primary D-channel port or the UDS1 circuit pack or DS1 Media Module. If there are problems with the [ISDN-PLK \(ISDN-PRI Signaling Link Port\)](#), also investigate [UDS1-BD \(UDS1 Interface Circuit Pack\)](#) or [MG-DS1 \(DS1 Interface Media Module\)](#).

## Remote Layer 3 Query (#637)

This test will query the far-end switch or terminal adapter to determine whether the signaling connection is functioning properly at Layer 3. It will select a B-channel in the in-service or maintenance service state and send an ISDN layer-3 SERVICE message, which requires a response from the far end. The test will not be performed if there are no B-channels in an appropriate ISDN service state (as when none are administered or they are all out of service).

**Note:**

Enter `status trunk grp#/mem#` or `status pri-endpoint` to see the service state.

A PASS indicates only that a message was successfully sent to the far-end switch or terminal adapter. The ISDN PRI Specification allows up to 2 minutes for a response.

Tests #639 and #636 check the health of the D-channels and DS1/UDS1 Interface circuit packs or DS1 Interface Media Modules. As shown in [Figure 106: Remote Layer 3 Query Test Diagram \(#637\)](#), this test goes one step further by checking the communication path from the processor, through the TDM/packet bus and DS1/UDS1 Interface circuit pack, or through the Media Module, and on to the far-end switch or terminal adapter. A special ISDN message is sent to the far-end switch or terminal adapter, which must respond within a specified amount of time. This test is designed to ensure that the communication path between the switch and the far end is up and operational, and that the two endpoints can properly exchange ISDN control messages.

**Figure 106: Remote Layer 3 Query Test Diagram (#637)**

For systems supporting circuit packs, [Figure 106: Remote Layer 3 Query Test Diagram \(#637\)](#) illustrates a UDS1 Interface circuit pack located in the PN. When the UDS1 board resides in a PN, there is additional PNC hardware connecting the packet buses of the IPSI PN and PN. Examples of such hardware are the Center Stage Switch and fiber-optic cables.

This test runs on [ISDN-SGR \(ISDN-PRI Signaling Group\)](#).

## Secondary Signaling Link Hardware Check (#639)

The ISDN-PRI Signaling Group D-channel port depends on the health of the TN464 UDS1 Interface circuit pack or DS1 Interface Media Module on which it resides. This test will fail if there are problems with the ISDN-PRI Secondary D-channel port or the UDS1 circuit pack or the DS1 Media Module. This test will abort if a Secondary D-channel is not administered for the signaling group. If there are problems with the ISDN-PRI Secondary Signaling Channel port (ISDN-PLK), also investigate the [UDS1-BD \(UDS1 Interface Circuit Pack\)](#), [DS1-BD \(DS1 Interface Circuit Pack\)](#), or [MG-DS1 \(DS1 Interface Media Module\)](#).

This test runs on [ISDN-SGR \(ISDN-PRI Signaling Group\)](#).

## Signaling Link Board Check (#643)

This test checks the health of the critical ATM TN230X circuit pack, DS1 Interface circuit pack, or DS1Interface media module hardware components required by the signaling link.

This test runs on [ATM-DCH \(ATM D-Channel Port\)](#) and [ISDN-PLK \(ISDN-PRI Signaling Link Port\)](#).

Table 429: Signaling Link Board Check (#643)

| Error Code | Test Result | Description / Recommendation                                                                                                                                                                                                                                                                                                                                                                                                  |
|------------|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|            | ABORT       | Internal system error<br>1. Retry the command at 1-minute intervals up to 5 times.                                                                                                                                                                                                                                                                                                                                            |
| 1700       | ABORT       | Rollabout video abort. The PRI terminal adapter associated with this D-channel port is detached from the circuit pack. This is normal when the rollabout video feature is enabled. To complete a test on this port:<br>1. Re-attach the disconnected PRI terminal adapter.<br>2. Enter <b>change ds1 location</b> to disable rollabout video on the board, and set the "Alarm when PRI Endpoint Detached" field to <b>y</b> . |
| 8          | FAIL        | The circuit pack is not in service.<br>1. Check the Hardware Error Log for entries logged against UDS1-BD or ATM-TRK. Consult <a href="#">UDS1-BD (UDS1 Interface Circuit Pack)</a> or <a href="#">ATM-TRK (Circuit Emulation Service Circuit Pack)</a> for repair procedures.                                                                                                                                                |
|            | PASS        | The circuit pack or media module transporting the ISDN-PRI Signaling Link Port is in service.                                                                                                                                                                                                                                                                                                                                 |

## Layer 2 Status Query Test (#647)

The Layer 2 Status Query Test checks the Layer 2 status of the ATM-SGRP or ISDN-PRI Signaling Channel (D-channel). This test will fail if there is a hardware failure or a facility problem, or if the primary and secondary ISDN-PRI D-channelchannels are not administered correctly.

The Primary and Secondary Signaling Link Hardware Tests (Tests #636 and #639), the ATM Remote Layer 3 Query Test (test #1291), and the Remote Layer 3 Query Test (#637) will detect most problems caused by hardware failures or incorrect administration.

This test runs on [ATM-SGRP \(ATM Signaling Group\)](#) and [ISDN-SGR \(ISDN-PRI Signaling Group\)](#).

**Table 430: Layer 2 Status Query Test (#647) 1 of 2**

| Error Code | Test Result | Description / Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                     |

## Stratum-3 Clock Alarm Query (#649)

The Stratum-3 Clock Alarm Query Test queries the Stratum-3 clock for its alarm status and reports the results of the query. The Stratum-3 clock provides the system with the following six alarm indications via the TN780 Tone-Clock circuit pack:

- 1 Reference A failed or CI card A failed.
- 1 Reference B failed or CI card B failed.
- 1 One power supply failed.
- 1 Every power supply failed.
- 1 One clock unit failed.
- 1 Every clock unit failed.

 **CAUTION:**

The removal of a card in the Stratum-3 clock may cause alarm(s) to be resolved and the query test to pass. However, the removed cards should still be replaced to restore the Stratum-3 clock to full service.

This test runs on [STRAT-3 \(Stratum-3 Clock\)](#) and [SYNC \(Port Network Synchronization\)](#).

| Error Code | Test Result | Description / Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |
|------------|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1          | FAIL        | <p>Either Reference A failed or CI card A failed. This condition usually indicates a failure of the DS1 reference. However, there may also be a failure of the CI card to which the reference is connected. The system technician dispatched to investigate this problem should take a spare CI card in case the CI card caused the failure.</p> <p>If you are NOT ON-SITE, use the following procedure:</p> <ol style="list-style-type: none"> <li>1. Enter <b>display errors</b> and look for DS1-BD errors. See <a href="#">DS1-BD (DS1 Interface Circuit Pack)</a> for the recommended repair procedures.</li> <li>2. If there are no DS1-BD errors <b>or</b> after resolving every DS1-BD error, enter <b>test synchronization r 4</b> to see if the alarm still exists. If every test repetition passes, the alarm no longer exists. Otherwise, the system technician should be dispatched with a spare CI card to use the following instructions on-site.</li> </ol> <p>If you are ON-SITE, use the following procedure:</p> <ol style="list-style-type: none"> <li>1. Look for a red LED on CI card A (i.e., the left CI card). If there is a red LED, replace the CI card if a spare is available. If no spare CI is available on-site, proceed to Step 3.</li> <li>2. If, after replacing the CI card, the red LED on the new CI card also lights, proceed to Step 3. Otherwise, enter <b>test synch r 4</b> to clear the alarm. If any test repetitions fail, follow the procedure for those failures.</li> <li>3. Enter <b>display errors</b> and look for DS1-BD errors. If there are errors, see <a href="#">DS1-BD (DS1 Interface Circuit Pack)</a> for the recommended repair procedures. If there are no DS1-BD errors, then proceed to Step 4.</li> <li>4. After every DS1-BD error has been resolved or if there are no DS1-BD errors, enter <b>test synch r 4</b> to clear the alarm and see if the alarm still exists. If any test repetitions fail, follow the procedures for those test failures.</li> <li>5. Check the DS1 reference A connections to the Stratum-3 clock.</li> </ol> |
|            |             | <b>2 of 5</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

| Error Code | Test Result | Description / Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |
|------------|-------------|---------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 8          | FAIL        | <p>Reference B failed or CI card B failed. This condition usually indicates a failure of the DS1 reference. However, there may also be a failure of the CI card to which the reference is connected. The system technician dispatched to investigate this problem should take a spare CI card in case the CI card caused the failure.</p> <p>If you are NOT ON-SITE, use the following procedure:</p> <ol style="list-style-type: none"> <li>3. Enter <b>display errors</b> and look for DS1-BD errors. See <a href="#">DS1-BD (DS1 Interface Circuit Pack)</a> for the recommended repair procedures.</li> <li>4. If there are no DS1-BD errors <b>or</b> after resolving every DS1-BD error, enter <b>test synchronization r 4</b> to see if the alarm still exists. If every test repetition passes, the alarm no longer exists. Otherwise, the system technician should be dispatched with a spare CI card to use the following instructions on-site.</li> </ol> <p>If you are ON-SITE, use the following procedure:</p> <ol style="list-style-type: none"> <li>1. Look for a red LED on CI card B (i.e., the right CI card). If there is a red LED, replace the CI card if a spare is available. If no spare CI is available on-site, proceed to Step 3.</li> <li>2. If, after replacing the CI card, the red LED on the new CI card also lights, proceed to Step 3. Otherwise, enter <b>test synch r 4</b> to clear the alarm. If any test repetitions fail, follow the procedure for those failures.</li> <li>3. Enter <b>display errors</b> and look for DS1-BD errors. If there are errors, see <a href="#">DS1-BD (DS1 Interface Circuit Pack)</a> for the recommended repair procedures. If there are no DS1-BD errors, then proceed to Step 4.</li> <li>4. After every DS1-BD error has been resolved or if there are no DS1-BD errors, enter <b>test synch r 4</b> to clear the alarm and see if the alarm still exists. If any test repetitions fail, follow the procedures for those test failures.</li> <li>5. Check the DS1 reference B connections to the Stratum-3 clock.</li> </ol> |
|            |             | <b>4 of 5</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

**Table 431: Stratum-3 Clock Alarm Query Test (#649) 5 of 5**

| Error Code    | Test Result | Description / Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

## Standby Reference Health Check Test (#651)

This test evaluates the quality of the external synchronization timing source for a standby IPSI or Tone-Clock circuit pack. Every administered synchronization timing source must be valid for this test to pass. If the Tone-Clock circuit and the synchronization timing sources are in different port networks, the EI circuit packs transport the timing sources to the tone-clock.

**Note:**

This test only runs on the standby IPSI or Tone-Clock circuit pack in a port network with more than one IPSI or Tone-Clock circuit pack (high- or critical-reliability option). The Tone-Clock circuit pack must be a TN780 with firmware 2 or higher, or a TN2182.

This test runs on the following maintenance objects:

- 1. [TDM-CLK \(TDM Bus Clock\)](#)
- 1. [TONE-BD \(Tone-Clock Circuit Pack\)](#)
- 1. [TONE-PT \(Tone Generator\)](#)

## Tie Trunk Dial Test (#747)

This test performs a dial tone/seizure test on a 2W LD tie trunk port. It seizes a trunk and outputs a pause digit. It aborts on ports administered as access endpoints.

This test runs on [TIE-TRK \(Analog Tie Trunk\)](#).

**Table 433: Tie Trunk Seizure Test (#747) 1 of 3**

| Error Code    | Test Result | Description / Recommendation                                                                                                                                                           |

## SNI Circuit Path Test (#755)

The SNI Circuit Path Test performs an on-board test of the circuit path. It runs on [SNI-BD \(SNI Circuit Pack\)](#) and [SNI-PEER \(SNI Peer Link\)](#).

Table 434: SNI Circuit Path Test (#755) 1 of 4

| Error Code | Test Result | Description / Recommendation                                                                                                                                     |
|------------|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2100       | ABORT       | Could not allocate the necessary system resources to run this test.<br>1. Retry the command at 1-minute intervals up to 3 times.                                 |

## SNI Destructive Facility Off-Board Test (#756)

**This test is destructive.**

The SNI runs a destructive looparound of the on- and off-board looparounds. This test returns the result of the off-board looparound, while Test 757 returns the result of the on-board looparound. For SNI-to-SNI fiber links, this test is run on both SNI circuit pack endpoints of the fiber link.

The test runs on the following maintenance objects:

- 1 [FIBER-LK \(Fiber Link\)](#)
- 1 [SNI-BD \(SNI Circuit Pack\)](#)

1 [SNI-PEER \(SNI Peer Link\)](#)

| 0             | NO BOARD    | <p>No board was detected by the test.</p> <ol style="list-style-type: none"> <li>1. Check that board is properly translated and inserted.</li> <li>2. Run the test again. If it fails, reset the board. An SNI should be reset instead of reseating the circuit pack. The <code>reset board</code> command should almost never be used on an SNI. It may be necessary to use <code>reset board</code> if the SNI circuit pack gets into a mode where it can't communicate with software. If an SNI with active errors and alarms is reset, the errors and alarms may take a while to come back. Therefore, <code>reset board</code> can mask real problems.</li> <li>3. Run the test again. If it fails, the ID chip on board may be bad. Replace the board and retest.</li> </ol> |
| <b>4 of 4</b> |             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

---

## SNI Destructive Facility On-board Test (#757)

**This test is destructive.**

The SNI runs a destructive looparound of the on- and off-board looparounds. This test returns the result of the on-board looparound, while Test 756 returns the result of the off-board looparound.

For SNI-to-SNI fiber links, this test is run on both SNI circuit pack endpoints of the fiber link.

This test runs on the following maintenance objects:

## Maintenance Demand Tests

- | [FIBER-LK \(Fiber Link\)](#)
- | [SNI-BD \(SNI Circuit Pack\)](#)
- | [SNI-PEER \(SNI Peer Link\)](#)

|---------------|-------------|----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|               | PASS        | No problems associated with this test are detected on the SNI(s).<br>1. Enter                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 0             | NO BOARD    | No board was detected by the test.<br>1. Check that board is properly translated and inserted.<br>2. Run the test again. If it fails, reset the board. An SNI should be reset instead of reseating the circuit pack. The <b>reset board</b> command should almost never be used on an SNI. It may be necessary to use <b>reset board</b> if the SNI circuit pack gets into a mode where it cot communicate with software. If an SNI with active errors and alarms is reset, the errors and alarms may take a while to come back. Therefore, <b>reset board</b> can mask real problems.<br>3. Run the test again. If it fails, the ID chip on board may be bad. Replace the board and retest. |
| <b>4 of 4</b> |             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                              |

---

## Configuration Audit (#759)

This test performs a Configuration Audit for an SNI or an SNC circuit pack. It runs on the following maintenance objects:

- 1 [FIBER-LK \(Fiber Link\)](#)
- 1 [SN-CONF \(Switch Node Configuration\)](#)
- 1 [SNC-BD \(Switch Node Clock Circuit Pack\)](#)
- 1 [SNC-LINK \(Switch Node Clock Link\)](#)
- 1 [SNC-REF \(Switch Node Clock Reference\)](#)
- 1 [SNI-BD \(SNI Circuit Pack\)](#)
- 1 [SNI-PEER \(SNI Peer Link\)](#)

For SNI circuit packs, this test determines if the circuit pack can communicate with:

- 1 the active SNC
- 1 its neighbor over the fiber link
- 1 peer SNIs

## Maintenance Demand Tests

For SNC circuit packs, this test determines if the circuit pack can communicate with the other SNC, and which SNIs the SNC can talk to over the serial communication channel.

This test is run by entering `test board` or `test board long` for SNI or SNC circuit packs, or `test fiber-link` for fiber links with SNI or EI endpoint(s).

Failures of this test cause entries in the error and alarm logs against Switch Node Configuration (SN-CONF) with the board location of the SNI or SNC.

For descriptions of result codes for this test, see:

- 1 [FIBER-LK Error codes and recommended actions](#) for fiber links.
- 1 [SNC-BD Error codes and recommended actions](#) when the circuit pack tested is a Switch Node Clock (circuit pack slots 10 or 12).
- 1 [SNI-BD Error codes and recommended actions](#) when the circuit pack tested is a Switch Node Interface (circuit pack slots 2–9 or 13–20).

## Incorrectly Connected Administered Fibers

Some physically connected fibers that do not match fiber administration can cause port network problems that are not detected and alarmed by this test. The symptoms will usually be phone calls not working correctly, and port network component alarms due to translation mismatches.

This test is unable to detect the case where an SNI is connected to the same type of board (EI or SNI) as administered but located in a different cabinet with the same carrier and same slot as the administered fiber endpoint. Enter `list fiber-link` to view the administered fiber endpoint. This test detects if the fiber endpoint connected to the SNI is in a different carrier and slot location than the administered fiber endpoint.

## Incorrectly Connected SNI-to-EI Fibers

If the SNI is connected to the same type of fiber endpoint as the administered fiber endpoint, but the location is the same as administered except for the cabinet, every phone call will work incorrectly; some phone calls will not go through and others will ring the wrong phone.

To check connectivity:

1. Enter `test led port-network` for each administered port network and verify that the LEDs on the correct port network are lit.
2. If the LEDs are not lit, enter `list fiber-link`. Check that the fiber connections to the port network are consistent with the administered fibers connections of the port network that does not light the LEDs as expected.
3. Run `test led switch-node` on each administered switch node carrier and verify that the LEDs on the correct carrier are lit.
4. If they are not, check the connectivity to the switch node carrier that does not light the LEDs as expected.

## Incorrectly Connected SNI-to-SNI Fibers between Three Switch Nodes

If the system has more than 2 switch nodes, SNI-to-SNI fibers administered between 2 switch nodes could be incorrectly connected to a third switch node. This is a problem that could occur during installation or when inter-switch node fibers are changed. For multiple fibers to a distant switch node, an incorrect connection would not appear as a problem unless this fiber is used for a system link to a port network connected to the distant switch node.

Enter `status sys-link` to determine the boards in the path from an IPSI connected PN to another specific PN. A specific SNI-to-SNI fiber connection must be in the system-link path to be checked with the port network LED test.

## Forcing SNI-to-SNI Fiber Connection

To force an SNI-to-SNI fiber connection to be used as a system-link, remove every SNI-to-SNI connection except the fiber link being tested at the distant switch node by removing SNI boards in the distant switch node.

1. Enter `status sys-link` to verify that the fiber selected for test is in the path to the PN connected to the distant switch node that will be used for the LED test.
2. Run `test led` on a port network to verify this fiber connection.
3. Repeat the above procedure for each of the SNI-to-SNI fibers terminating on the distant switch node.

## Testing Multiple Fiber Connections

To test multiple fiber connections to a distant switch node:

1. Enter `list fiber-link` to determine the number of SNI-to-SNI fibers that are administered to and terminate on the distant switch node.
2. Run `test led port-network` on a PN connected to the distant switch node, and verify the LEDs on the correct PN are lit.
3. Enter `status sys-link` and select the active EI in the IPSI connected PN connected to the distant PN under test. The display will show the path from the IPSI connected PN and the SNI-to-SNI fiber being used.
4. If the PN's LEDs are lit and there are multiple fibers to the distant switch node, remove the SNC that is listed by `list fiber-link` for this path.

If the PN's LEDs are not lit, enter `list fiber-link` to verify that the fiber connections to the PN are consistent with the administration assignments.

5. Enter `status sys-link` to determine the new path from the IPSI connected PN to the distant switch.

## Maintenance Demand Tests

6. Run `test led port-network` on the port network connected to the distant switch node, and verify that the LEDs on the correct PN are lit.
7. Repeat steps 4 – 6 until every SNI-to-SNI fiber connection to the distant switch has been tested.

---

## FIBER-LK Error codes and recommended actions

The following table contains the error codes and recommended actions for [FIBER-LK \(Fiber Link\)](#).

**Table 438: FIBER-LK Configuration Audit (#759) 1 of 9**

| <b>Error Code</b> | <b>Test Result</b> | <b>Description / Recommendation</b>                                                                                          |
|-------------------|--------------------|------------------------------------------------------------------------------------------------------------------------------|
| 2100              | ABORT              | Could not allocate the necessary system resources to run this test.                                                          |
| 2300              |                    | The downlink message necessary to run this test could not be sent.                                                           |
| 2301              |                    | The timer could not be set before sending the downlink message.<br>1. Retry the command at 1-minute intervals up to 3 times. |
|                   |                    | <b>1 of 9</b>                                                                                                                |

Table 438: FIBER-LK Configuration Audit (#759) 2 of 9

| Error Code | Test Result | Description / Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |
|------------|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 2306       | ABORT       | <p>An SNI circuit pack on the fiber link is not responding to test requests.</p> <ol style="list-style-type: none"> <li>1. Run <code>test led switch-node</code> for the switch node(s) where the SNI(s) reside to verify whether the LEDs on the board(s) light. Follow the steps below for the SNI(s) that had no LEDs light.</li> <li>2. If the LEDs on the other boards in the carrier light but the LEDs on this board do not light, run Test #760 using <code>test board location long</code> for the active SNC in this carrier. Wait 5 minutes, then try step 1 one more time. If the LEDs on this board still do not light, replace the board. Replacing an SNI may be service interrupting. Refer to <a href="#">SNI-BD (SNI Circuit Pack)</a> for the procedure to replace an SNI.</li> <li>3. If none of the LEDs light for the boards in the same carrier as this board, fix any problems associated with the connectivity of this carrier to the server.</li> <li>4. Enter <code>list fiber-link</code> to determine the fiber connections to this carrier. Check the LEDs on every SNI and EI, and fix any fiber problems.</li> <li>5. Enter <code>display errors</code>, and follow the repair procedures for any <a href="#">EXP-INTF (Expansion Interface Circuit Pack)</a> error entries associated with the PN. ## SNC-BD Error codes and recommended actions

The following table contains the error codes and recommended actions for [SNC-BD \(Switch Node Clock Circuit Pack\)](#).

**Table 439: SNC-BD Configuration Audit (#759) 1 of 5**

| Error Code | Test Result | Description / Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |

Retry the command at 1-minute intervals up to 3 times.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                |
| 2306       | ABORT       | The SNC circuit pack is not responding to test requests sent by software.<br>1. Run <code>test led switch-node</code> for the switch node where this board resides to verify whether the LEDs on the board light.<br>2. If the LEDs on the other boards in the carrier light, but the LEDs on this board do not light, run test 760 using <code>test board location 1</code> for the active SNC in this carrier. Wait 5 minutes, then try step 1 one more time. If the LEDs on this board still do not light, replace this board. Replacing an SNC may be service interrupting. See <a href="#">SNC-BD (Switch Node Clock Circuit Pack)</a> for replacing an SNC.<br>3. If none of the LEDs light for the boards in the same carrier as this board, fix any problems associated with the connectivity of this carrier to the server.<br>a. Enter <code>list fiber-link</code> to check the fiber connections to this carrier.<br>b. Check the LEDs on every SNI and EI, and fix any fiber problems.<br>c. Enter <code>display errors</code> and follow the repair procedures for any <a href="#">EXP-INTF (Expansion Interface Circuit Pack)</a> error entries associated with the controlling IPSI connected PN.<br>d. Follow the repair procedures for any <a href="#">SYNC (Port Network Synchronization)</a> , <a href="#">SNI-BD (SNI Circuit Pack)</a> , <a href="#">SNC-BD (Switch Node Clock Circuit Pack)</a> , <a href="#">FIBER-LK (Fiber Link)</a> , or <a href="#">SNI-PEER (SNI Peer Link)</a> error entries. |

| 0          | NO BOARD    | <p>No board was detected by the test.</p> <ol style="list-style-type: none"> <li>1. Check that SNC board is properly translated and inserted.</li> <li>2. Run the test again. If it fails, reset the board. An SNC should be reset instead of reseating the circuit pack. The <b>reset board</b> command should almost never be used on an SNC. It may be necessary to use <b>reset board</b> if the SNC circuit pack gets into a mode where it cannot communicate with software. If an SNC with active errors and alarms is reset, the errors and alarms may take a while to come back, therefore <b>reset board</b> can mask real problems.</li> <li>3. Run the test again. If it fails, the ID chip on board may be bad. Replace the board and retest.</li> </ol> |
|            |             | <b>5 of 5</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                        |

## SNI-BD Error codes and recommended actions

The following table contains the error codes and recommended actions for [SNI-BD \(SNI Circuit Pack\)](#).

Table 440: SNI-BD Configuration Audit (#759) 1 of 6

| Error Code | Test Result | Description / Recommendation                                                                                                                                                       |

## Processor Route Audit Test (#760)

This test sends a processor route to every SNI in the carrier for which `test board location` was run. A processor route enables an SNI board to send uplink messages to the server by providing the board with a specific sequence of boards for routing messages up to the server. Without a processor route, an SNI cannot send any inline errors to the server.

As each SNI receives its processor route, the SNI returns a “board insertion” uplink message, and, if not already inserted, the server’s software inserts that board. Depending on the configuration, each SNI board is sent either one or two processor routes.

Enter `test led` or `list config carrier` to see if the boards are inserted.

The processor route test is run as part of the long test sequence for SNC boards. It runs on the following maintenance objects:

- 1 [SN-CONF \(Switch Node Configuration\)](#)
- 1 [SNC-BD \(Switch Node Clock Circuit Pack\)](#)
- 1 [SNC-LINK \(Switch Node Clock Link\)](#)
- 1 [SNC-REF \(Switch Node Clock Reference\)](#)

Table 441: Processor Route Audit Test (#760) 1 of 2

| Error Code    | Test Result | Description / Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

## Switch Node Interface Reset Test (#761)

**This test is destructive.**

This test resets the SNI circuit pack using `reset board location` when an SNI circuit pack's location is entered. The SNI is reset via the active SNC circuit pack in the carrier. If the SNI is connected to an IPSI-connected PN's EI, the SNI is reset via its IPSI-connected PN's EI neighbor. If an SNI with a non IPSI-connected PN's EI or another SNI as its neighbor could be reset via the active SNC (i.e., if no software communication exists between the active SNC and the server), an attempt will be made to reset the SNI via its neighbor.

An SNI should be reset instead of reseating the circuit pack. The `reset board` command should almost never be used on an SNI. It may be necessary to use `reset board` if the SNI circuit pack gets into a mode where it could not communicate with software.

If an SNI with active errors and alarms is reset, the errors and alarms may take a while to come back, therefore `reset board` can mask real problems.

This test runs on [SNI-BD \(SNI Circuit Pack\)](#) and [SNI-PEER \(SNI Peer Link\)](#).

|               | PASS        | The "reset" message was sent out successfully to the active SNC or to the SNI's neighbor. A PASS does not necessarily mean the SNI circuit pack was successfully reset. The reset can be verified by checking that the red and green LEDs turn on and then turn off. If an SNI circuit pack fails one of the firmware tests run during its reset sequence, the red LED will stay on and the circuit pack should be replaced.                                                                                                                                                                                                                                                                                                                                                   |
| 0             | NO BOARD    | No board was detected by the test.<br><ol style="list-style-type: none"> <li>1. Check that board is properly translated and inserted.</li> <li>2. Run the test again. If it fails, reset the board. An SNI should be reset instead of reseating the circuit pack. The <code>reset board</code> command should almost never be used on an SNI. It may be necessary to use <code>reset board</code> if the SNI circuit pack gets into a mode where it cannot communicate with software. If an SNI with active errors and alarms is reset, the errors and alarms may take a while to come back, therefore <code>reset board</code> can mask real problems.</li> <li>3. Run the test again. If it fails, the ID chip on board may be bad. Replace the board and retest.</li> </ol> |

## Packet Neighbor Link Test (#767)

This test checks the packet path of the neighbor circuit pack and the peer circuit packs. A packet is sent from the SNI being tested to the peer SNIs and to the neighbor EI or SNI. If the other EI or SNI sends the same data back in the packet, this test passes. Otherwise, this test fails.

## Maintenance Demand Tests

This test runs on [SNI-BD \(SNI Circuit Pack\)](#) and [SNI-PEER \(SNI Peer Link\)](#).

**Table 443: Packet Neighbor Link Test (#767) 1 of 5**

| Error Code | Test Result | Description / Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

## Fiber Link Reset Test (#768)

**This test is destructive.**

This test resets both endpoints of the fiber link and is executed via `reset fiber-link F P`. Any DS1 converter circuit packs on the fiber link are not reset. The `reset fiber-link` command should almost never be used. It may be necessary to use it when the endpoint circuit packs enter a mode in which they cot communicate with software. When necessary, always reset fiber endpoints with the command instead of reseating the endpoint circuit packs.

For EI-to-EI fibers that connect an IPSI PN, the EI on the PN is reset first followed by the EI on the IPSI PN. For EI-to-EI fiber links that connect two PNs, one EI is reset first followed by the other.

For an EI-SNI fiber link in which the EI is on the PN, the SNI is reset first followed by the EI.

For an SNI-to-SNI fiber link, the SNI farthest from the PN is reset first followed by the SNI nearest to the PN.

When an EI endpoint is reset, the [Expansion Interface Reset Test \(#336\)](#) is executed. When an SNI endpoint is reset, the [Switch Node Interface Reset Test \(#761\)](#) is executed.

This test starts the other reset test previously mentioned and returns PASS without waiting for the results of the other reset test. For a better indication of how the other reset tests are running, enter `reset board location` on each individual fiber link endpoint.

This test runs on [FIBER-LK \(Fiber Link\)](#).

**Table 444: Fiber Link Reset Test (#768)**

| Error Code | Test Result | Description / Recommendation                                                                                                                                                                                                        |
|------------|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1703       | ABORT       | Both fiber endpoints are in the hardware path for INLs to their respective switch node carriers and, therefore, cot get a response from this test.<br>1. Reset the individual fiber-link endpoints using <code>reset board</code> . |
| 2500       | ABORT       | Internal system error<br>1. Retry the command at 1-minute intervals up to 3 times.                                                                                                                                                  |
|            | PASS        | The reset of both fiber endpoints successfully completed.                                                                                                                                                                           |
|            |             |                                                                                                                                                                                                                                     |

---

## Failure Audit (#777)

This test queries the SNI(s) on the fiber link for any existing failures and unacknowledged cleared failure messages. Each failure generates an error and alarm entry against SNI-BD, SNI-PEER, or FIBER-LK. An unacknowledged cleared failure message is a message sent by the SNI circuit pack to software indicating that a previous failure is now gone, and the SNI circuit pack did not receive a message from software indicating that the failure message was received by software.

If no failures are detected by the SNI circuit pack, this test will pass.

If this test reports failures, the results of `test fiber-link` will display FAIL with no FAIL code. The error log must then be displayed using `display errors` with category PNC to view SNI-BD and FIBER-LK errors. Enter `display errors` with category PNC-PEER to view SNI-PEER errors.

This test is not run for EI-to-EI fiber links. For EI-to-SNI fiber links, this test is run on the SNI circuit pack endpoint of the fiber link. For SNI-to-SNI fiber links, this test is run on both SNI circuit pack endpoints of the fiber link.

This test runs on the following maintenance objects:

- 1 [FIBER-LK \(Fiber Link\)](#)
- 1 [SNC-BD \(Switch Node Clock Circuit Pack\)](#)
- 1 [SNC-LINK \(Switch Node Clock Link\)](#)
- 1 [SNC-REF \(Switch Node Clock Reference\)](#)

## Maintenance Demand Tests

## SNC On-Board Test (#778)

This test queries the SNC circuit pack for status of the on-board background tests. These tests include an SNC on-board microcontroller test, clock test, an SNC on-board Stratum-3 oscillator test, and TPN microcontroller test.

This test runs on the [SNC-BD \(Switch Node Clock Circuit Pack\)](#) maintenance object.

**Table 446: SNC On-Board Test (#778) 1 of 2**

| Error Code                           | Test Result | Description / Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

Replace the SNC circuit pack.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
|               | PASS        | No problems exist with the on-board functions verified by this test.                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                               |
| 0             | NO BOARD    | No board was detected by the test.<br>2. Check that SNC board is properly translated and inserted.<br>3. Run the test again. If it fails, reset the board. An SNC should be reset instead of reseating the circuit pack. The <b>reset board</b> command should almost never be used on an SNC. It may be necessary to use <b>reset board</b> if the SNC circuit pack gets into a mode where it cannot communicate with software. If an SNC with active errors and alarms is reset, the errors and alarms may take a while to come back, therefore <b>reset board</b> can mask real problems.<br>4. Run the test again. If it fails, the ID chip on board may be bad. Replace the board and retest. |
| <b>2 of 2</b> |             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

## TPN Test (#779)

This test queries the SNC circuit pack for the status of the ROM and internal RAM background tests for the TPN microcontroller.

This test runs on the [SNC-BD \(Switch Node Clock Circuit Pack\)](#) maintenance object.

**Table 447: TPN Test (#779) 1 of 3**

| Error Code | Test Result | Description / Recommendation                                                                                                     |
|------------|-------------|----------------------------------------------------------------------------------------------------------------------------------|
| 2100       | ABORT       | Could not allocate the necessary system resources to run this test.                                                              |
| 2300       |             | The downlink message necessary to run this test could not be sent.                                                               |
| 2301       |             | The software timer could not be set for sending the downlink message.                                                            |
| 2302       |             | Software received unexpected message data from the SNC circuit pack.                                                             |
| 2303       |             | The SNC circuit pack responded that the test requested is not valid.                                                             |
| 2304       |             | SNC circuit pack is not able to run the test requested by software.<br>1. Retry the command at 1-minute intervals up to 3 times. |
|            |             | <b>1 of 3</b>                                                                                                                    |

## Switch Node Clock Reset Test (#780)

### This test is destructive.

This test resets the SNC circuit pack using **reset board location** when an SNC circuit pack location is entered. If the system has PNC duplication, the active SNC on the active PNC cot be reset.

If the SNC is active and **reset board** is executed, an SNI in the same carrier as the SNC will be told by software to reset the SNC via the TPN link. If no inserted SNIs in the same carrier as the SNC can successfully reset the SNC, software will send a “reset” message directly to the SNC. Software first tries to reset the SNC via an SNI in case the SNC is insane because the latter method (sending the “reset” message directly to the SNC) will not work if the SNC is insane.

If an active SNC is reset and a standby SNC exists in the same switch node carrier, the standby SNC becomes active. Enter **set switch-node-clock location** to make a standby SNC active.

If the SNC is standby and **reset board** is executed, the active SNC is told by software to reset the standby SNC via the TPN link.

An SNC should be reset instead of reseating the circuit pack. The **reset board** command should almost never be used on an SNC. It may be necessary to use **reset board** if the SNC circuit pack gets into a mode where it cot communicate with software.

## Maintenance Demand Tests

This test runs on the [SNC-BD \(Switch Node Clock Circuit Pack\)](#) maintenance object.

| Error Code    | Test Result | Description / Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                      |
|---------------|-------------|-------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|               | PASS        | The “reset” message was sent out successfully to the active SNC or to an SNI. A PASS does not necessarily mean the SNC circuit pack was successfully reset. The reset can be verified by checking that the red and green LEDs turn on and then turn off. If an SNC circuit pack fails one of the firmware tests run during its reset sequence, the red LED will stay on and the circuit pack should be replaced.                                                                                                                                                                                                                                                                                                                                                  |
| 0             | NO BOARD    | <p>No board was detected by the test.</p> <ol style="list-style-type: none"> <li>1. Check that SNC board is properly translated and inserted.</li> <li>2. Run the test again. If it fails, reset the board. An SNC should be reset instead of reseating the circuit pack. The <b>reset board</b> command should almost never be used on an SNC. It may be necessary to use <b>reset board</b> if the SNC circuit pack gets into a mode where it cot communicate with software. If an SNC with active errors and alarms is reset, the errors and alarms may take a while to come back, therefore <b>reset board</b> can mask real problems.</li> <li>3. Run the test again. If it fails, the ID chip on board may be bad. Replace the board and retest.</li> </ol> |
| <b>3 of 3</b> |             |                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                   |

## Reset Board Test (#787)

**This test is destructive.**

A DS1 converter circuit pack is reset using **reset board**. *location*. When the circuit pack is reset, firmware executes a series of diagnostic tests on the circuit pack. The results of these tests are queried from the board when the board is inserted after completion of the reset sequence. If any of the diagnostic tests fail, the error log will have an entry of Error Type 1 for this circuit pack’s location, and the alarm log will have an entry of ON-BOARD MAJOR alarm.

The reset sequence will take about one minute to complete and runs on the [DS1C-BD \(DS1 Converter Circuit Pack\)](#).

**Table 449: Reset Board Test (#787)**

| Error Code | Test Result | Description / Recommendation                                                                                                                                                                                                                                                                                                                                                                   |

Enter <b>display alarms</b> to check the alarm log for any ON-BOARD MAJOR alarms. |
| 0          | NO BOARD    | See <a href="#">NO BOARD</a> for the repair procedures.                                                                                                                                                                                                                                                                                                                                        |
|            |             |                                                                                                                                                                                                                                                                                                                                                                                                |

# Far-End DS1 Converter Circuit Pack Loopback Test (#788)

This test is destructive.

This test is executed by the TN574 DS1 Converter circuit pack only. See [DS1 Facilities Connectivity Test \(#790\)](#) for testing the TN1654 DS1 Converter.

This test starts at the specified DS1 converter circuit pack location and loops all fiber time slots at the far edge Fiber Optic Interface of the DS1 converter circuit pack at the other end of the DS1 converter complex. See [Figure 107: Far-End DS1 Converter Loopback Configuration](#).

The test sends digital data through every administered DS1 facility channel. Two different test patterns are used: hexadecimal values 55 and AA.

For a standard-, duplex-, or high-reliability system (no PNC duplication), this test can only be executed at the endpoint that is closer to the server relative to the neighbor DS1 converter circuit pack because of its impact on the system control links. The completion of the test is delayed in this configuration to wait for the recovery of the system control links. For a critical-reliability system (PNC duplication), this test can be executed on any DS1 converter circuit pack. This test runs on the [DS1C-BD \(DS1 Converter Circuit Pack\)](#) maintenance object.

## Far-End Lightwave Transceiver Loopback Test (#789)

**This test is destructive.**

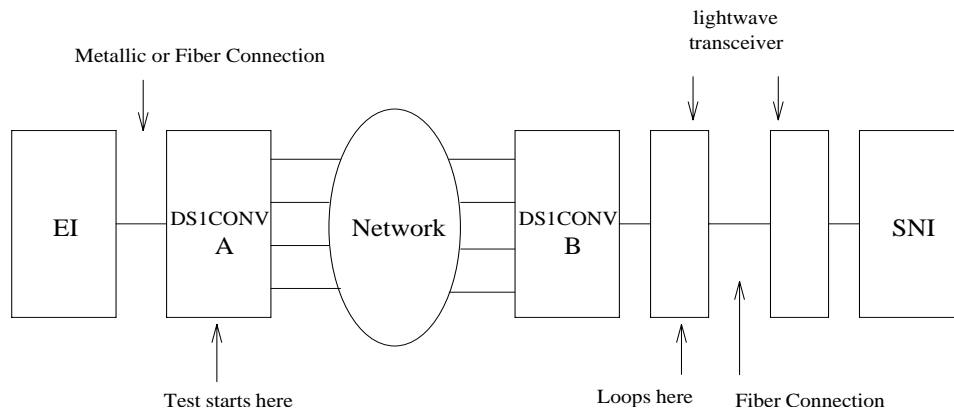

This test is executed on the TN574 DS1 Converter circuit pack only. [DS1 Facilities Connectivity Test \(#790\)](#) covers this testing on the TN1654 DS1 Converter.

This test starts at the specified DS1 converter circuit pack location and loops at the Fiber Optic Terminator (lightwave transceiver) that is connected to the DS1 converter circuit pack at the other end of the DS1 converter complex. See [Figure 108: Far-End Lightwave Transceiver Loopback Test](#).

The test sends digital data through every DS1 facility channel. Two different test patterns are used, these are hexadecimal values 55 and AA.

For a standard-, duplex-, or high-reliability system (no PNC duplication), this test can only be executed at the endpoint that is closer to the server relative to the neighbor DS1 converter circuit pack because of its impact on the system control links. The completion of the test will be delayed in this configuration to wait for the recovery of the system control links. For a critical-reliability system (PNC duplication), the test can be executed on any DS1 converter circuit pack. This test runs on the [DS1C-BD \(DS1 Converter Circuit Pack\)](#) maintenance object.

## DS1 Facilities Connectivity Test (#790)

This test is destructive.

## Maintenance Demand Tests

The DS1 Facilities Connectivity Test checks the correct connectivity of the DS1 facilities at opposite ends of the DS1 converter complex.

For TN574 DS1 Converter circuit packs, this test sends digital data through each time slot of every DS1 facility channel. Two different test patterns are used: hexadecimal values 55 and AA.

For TN1654 DS1 Converter circuit packs, this test provides error codes that point to the exact fault. The TN1654 test specifically identifies the two DS1 facilities that are cross-connected at the near and far ends of the DS1 converter complex. In addition, a fault code will indicate the condition of not being able to loop-up the far end, as required to run the test, due to the packet DS1 facility being down.

The TN1654 connectivity test sends digital data through only one time slot. Instead of looping back the facility to itself, the TN1654 version of the test loops-up the other three facilities. If the test pattern comes back, the firmware fails the test due to an incorrect connection between DS1 facilities. It should be noted that this test will pass and give no indication of problems if the non-packet facilities are down.

For a standard-, duplex-, or high-reliability system (no PNC duplication), this test can only be executed at the endpoint that is closer to the server relative to the neighbor DS1 converter circuit pack because of its impact on the system control links. In addition, for TN574 DS1 converter boards, the completion of the test will be delayed in this configuration to wait for the recovery of the system control links. For a critical-reliability system (PNC duplication), the test can be executed on any DS1 converter circuit pack.

This test runs on [DS1C-BD \(DS1 Converter Circuit Pack\)](#).

## DS1C Board Options Audit (#795)

This test sends the administered circuit pack options to the DS1 converter circuit pack. Options are sent to both DS1 converter circuit packs at the same time to prevent any transitional mismatch of options.

The following data is sent to the TN574 DS1 converter circuit pack:

- 1 system-reliability configuration
- 1 master and slave endpoints for framing, which is determined by the relative position of the circuit pack to the server
- 1 facility mask (whether each facility is installed)
- 1 clock reference mask (whether:
  - each facility can be used as a clock-reference source
  - the board is being used as a network-timing source)
- 1 packet compatible mask (whether each facility is packet compatible)
- 1 facility information for line coding, framing mode, and line compensation

The following data is sent to the TN1654 DS1 converter circuit pack:

- 1 system-reliability configuration
- 1 master and slave endpoints for framing, which is determined by the relative position of the circuit pack to the server)
- 1 facility mask (whether each facility is installed)
- 1 idle code
- 1 CRC-enabled/-disabled flag (sent in E1 mode only)
- 1 facility information for line coding and line compensation (sent in T1 mode only).

This test runs on the [DS1C-BD \(DS1 Converter Circuit Pack\)](#) maintenance object.

## Far-End Internal Loopback Test (#797)

This test is destructive.

This test starts at the specified DS1 converter circuit pack location, traverses over the specified facility, and loops at the internal facility interface on the other DS1 converter circuit pack in the DS1 converter complex. See [Figure 109: Far-End Internal Loopback Test Configuration](#).

The test sends digital data through every DS1 channel on this facility. For TN574 DS1 Converter facilities, test patterns are sent through every DS1 channel. For TN1654 DS1 Converter facilities, test patterns are sent through one DS1 channel.

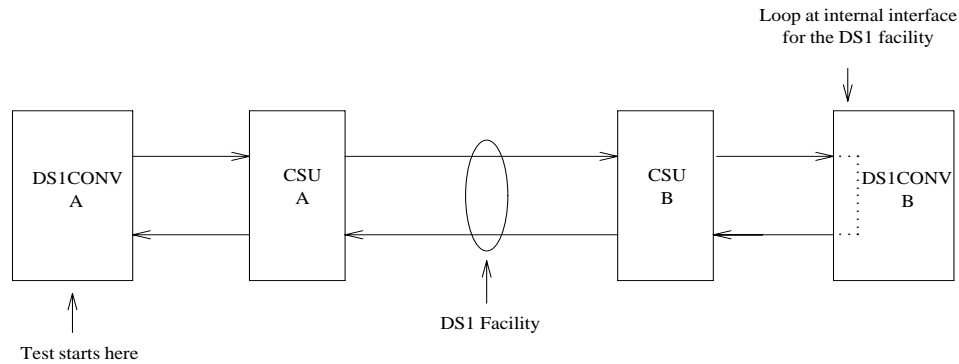

If there is only one DS1 facility available, the system will not allow that last facility to be busied out. In that case, the DS1 converter circuit pack must be busied out before executing this test.

For a standard-, duplex-, or high-reliability system (no PNC duplication), if there is only one DS1 facility available, then this test can only be executed at the endpoint that is closer to the server relative to the neighbor DS1 converter circuit pack because of its impact on the system control links. For TN574 DS1 converter boards, the completion of the test will be delayed in this configuration to wait for the recovery of the system control links. For a critical-reliability system (PNC duplication) or for a system with multiple DS1 facilities, the test can be executed on any DS1 converter circuit pack.

If the test passes on a TN1654 DS1 facility, the *round trip delay time* appears in milliseconds in the `Error Code` field. The round trip delay time is the length of time in milliseconds it takes for the firmware to receive the test pattern after it has been sent.

This test runs on the [DS1-FAC \(DS1 Facility\)](#) maintenance object.

|---------------|-------------|-----------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
|               | FAIL        | <p>Far-End Internal loopback failed. A problem exists between DS1 converter A and DS1 converter B's internal interface for the DS1 facility. See <a href="#">Figure 109: Far-End Internal Loopback Test Configuration</a>.</p> <ol style="list-style-type: none"> <li>1. Enter <code>display errors</code> and follow the associated repair procedures for any on-board <a href="#">DS1C-BD (DS1 Converter Circuit Pack)</a> errors on this DS1 converter circuit pack and the DS1 converter circuit pack at the other end of the DS1 converter complex.</li> <li>2. If the network is used instead of private T1 lines, verify that the DS1 facility and the network are using the same Line Coding. For TN574 boards and TN1654 boards in T1 mode, also verify that the Framing Mode used is the same. Enter <code>list fiber-link</code> and <code>display fiber-link</code> to check the values for this DS1 facility. Contact T1 Network Service to check the modes used by the network. See <a href="#">Line Coding</a> and <a href="#">Framing Mode</a> for details on how these options apply to the TN574 and TN1654 DS1 converter boards.</li> <li>3. Isolate the problem by running the Near-End External Loopback test (#799) with <code>test ds1-facility location external-loopback</code>, first at this end and then at the other end of the DS1 converter complex. Set up loopbacks at different points as shown in the description diagram for Test #799, and follow repair procedures described for <a href="#">Near-End External Loopback Test (#799)</a>.</li> <li>4. If the problem could not be found by near-end external loopback tests, the fault should be between the CSU A and the CSU B. Contact T1 Network Service to resolve the problem. Also see the repair procedures for Error Type 1025 (loss of frame alignment) for <a href="#">DS1C-BD (DS1 Converter Circuit Pack)</a>.</li> </ol> |
| Any           | PASS        | <p>Transmission through the path of the loopback is successful. TN1654 DS1 facilities will display the round trip delay time in milliseconds in the <code>Error Code</code> field. ## DS1 Interface Options Audit (#798)

This test sends the administered DS1 Interface options to the DS1 converter circuit pack. Options are sent to both DS1 converter circuit packs at the same time to prevent any transitional mismatch of options.

The following DS1 facility options are sent to the TN574 DS1 converter circuit pack: Framing Mode, Line Coding and DS1 converter-1 and DS1 converter-2 Line Compensation.

The following DS1 facility options are sent to the TN1654 DS1 converter circuit pack: Line Coding, and DS1 converter-1 and DS1 converter-2 Line Compensation (T1 only). These option fields appear on the Fiber-link Administration screen.

This test runs on the [DS1-FAC \(DS1 Facility\)](#) maintenance object.

## Near-End External Loopback Test (#799)

**This test is destructive.**

This test starts at the specified DS1 converter circuit pack location, traverses over the specified facility, and loops back at the manually hard-wired external loopback device. Depending on the type of physical connectivity of the DS1 facility, special tools, cables or connectors may be required to make the hard-wired loopbacks.

To isolate a problem, set the loopback first at the loopback point LB 1, and then at the loopback point LB 2. See [Figure 110: Loopback Points for Test #799](#) and [Figure 19: DS1 Facility Connections](#). Place the loopbacks at as many points as your CSU capabilities will allow. Hard-wired loopbacks at the far end are not desirable, because the equalization-level adjustments may cause problems.

Every part of this test is executed under firmware control and the result is sent back to the system. The test is executed by sending digital data through every DS1 channel on this DS1 facility.

This test is executed using `test ds1-facility location external-loopback`. It is not part of the long test sequence because it requires modifications to the physical connectivity of the DS1 facility.

If there is only one DS1 facility available, the system will not allow the last facility to be busied out. In that case, the DS1 converter circuit pack must be busied out before executing this test.

For a standard-, duplex-, or high-reliability system (no PNC duplication), if there is only one DS1 facility available, then this test can only be executed at the endpoint that is closer to the server relative to the neighbor DS1 converter circuit pack because of its impact on the system control links. For a critical-reliability system (PNC duplication) or for a system with multiple DS1 facilities, the test can be executed at any DS1 converter circuit pack.

If the test passes on a TN1654 DS1 facility, the *round trip delay time* will be displayed in milliseconds in the `Error Code` field. The round trip delay time is defined as the length of time in milliseconds it takes for the firmware to receive the test pattern after it has been sent. This measurement is taken on the last DS1 channel tested.

This test runs on the [DS1-FAC \(DS1 Facility\)](#) maintenance object.

## Automatic Transmission Test (#844-848)

**Note:**

Tests #844–848 are not supported on an International switch.

These tests are run by the Automatic Transmission Measurement System (ATMS). They are not part of the long or short trunk test sequences. Instead, they are run using the command **test analog-testcall** or as part of ATMS scheduled testing. For more information, see *Maintenance Procedures (03-300432)*.

The test call is run from an analog port on a TN771 Maintenance/Test circuit pack. It attempts to seize a port and make a call to a terminating test line (TTL) on the trunk's far end. Transmission performance measurements are made and compared to administered thresholds. Errors are generated when results fall outside of "marginal" or "unacceptable" thresholds. Detail and summary measurement reports are obtainable using **list testcalls**.

## Maintenance Demand Tests

See the test `analog-testcall` section on the Maintenance Commands for Avaya Aura™ Communication Manager, Media Gateways and Servers (03-300431) for the command syntax. The command options and the associated tests which are executed for `test analog-testcall` are:

| Test Command                      | Option                | Test executed |
|-----------------------------------|-----------------------|---------------|
| <code>test analog-testcall</code> | <i>supervision</i>    | 844           |
| <code>test analog-testcall</code> | <i>full</i>           | 845           |
| <code>test analog-testcall</code> | <i>no-selftest</i>    | 846           |
| <code>test analog-testcall</code> | <i>no-return-loss</i> | 847           |
| <code>test analog-testcall</code> | <i>no-st-or-rl</i>    | 848           |

These tests run on [CO-TRK \(Analog CO Trunk\)](#) and [TIE-TRK \(Analog Tie Trunk\)](#).

---

## Packet Interface Memory Checksum Test (#884)

This test sends a message to the Packet Interface module to run memory checksum tests on the Boot PROM and FLASH memory on the IPSI circuit pack. If the test fails, the Packet Interface module remains operational until a reset is executed. The Packet Interface is then placed in an out-of-service state.

This test runs on [PKT-INT \(Packet Interface\)](#).

## Packet Interface Private Looparound Test (#885)

This test requests the Packet Interface to run its three private looparound tests: Level-2 Link Looparound, Level-3 Link Looparound, and Broadcast Path Looparound. These tests verify the health of the circuit pack's packet bus interface as well as the translation RAM, inward and outward bound data paths, parity indications and CRC calculations.

These tests are also run as part of the `reset` command. If any of the looparound tests fail, the Packet Interface is put in the out-of-service state. Repair procedures associated with Abort Code 1137 (out of service) should be followed.

This test runs on [PKT-INT \(Packet Interface\)](#).

---

## Packet Interface Maintenance Looparound Test (#886)

This test checks whether an IPSI circuit pack's Packet Interface module correctly sends and receives data. It establishes a LAPD link from the IPSI's Packet Interface module back to the same Packet Interface module, and transmits and receives test data over that testing link. While timing signals from the packet bus are used for the data transfer, the data itself is looped around on the circuit pack at the interface to the packet bus and does not get sent over the packet bus.

### Note:

In a high- or critical-reliability system (duplicated IPSIs), this test does not run on a standby IPSI's Packet Interface module. However, a failure of the Maintenance Looparound test may cause an IPSI interchange that reports an alarm (associated with the looparound failure, Error Code 769) against the standby IPSI's Packet Interface module. If so, and if every other Packet Interface test in `test packet-interface location long` sequence passes, enter `set ipserver-interface` to force the standby IPSI to go active. Then, enter `test packet-interface location` to run the Maintenance Looparound test, and verify that the problem cleared.

## Maintenance Demand Tests

This test runs on [PKT-INT \(Packet Interface\)](#).

## Packet Interface Read and Clear Counters (#887)

This test sends commands to read Packet Interface error counters located on the IPSI circuit pack. It also verifies the message interface between the server and the Packet Interface.

This test checks different Packet Interface counters **S8700-series Fiber-PNC**: depending on whether the Packet Interface module is on the active or standby IPSI.

Running this test on the active IPSI circuit pack's Packet Interface module reads and clears the Parity Error counter and FIFO Overflow counter. **S8700-series Fiber-PNC**: Those counters are not used when a Packet Interface module is in standby mode.

**S8700-series Fiber-PNC**: Running this test on the standby IPSI circuit pack's Packet Interface module, reads but does not clear a Translation RAM counter. The Translation RAM counter is not cleared since the number of bad translation RAM locations indicates bad locations that cannot be used.

For an active Packet Interface module, information about the number of bad Translation locations is sent to maintenance software as an inline error from the IPSI circuit pack, so it is not necessary to read a counter location.

This test runs on [PKT-INT \(Packet Interface\)](#).

## Active-Standby Peer Link Test (#888)

The Active-Standby Peer Link test is run only in a system equipped with the high- or critical-reliability configuration. It verifies that a peer link can be set up between the active and standby PKT-INTs. A peer link is a logical connection established between the packet bus and an IPSI circuit pack's Packet Interface module for both active and standby IPSIs. This link forwards data and control messages between the active and standby PKT-INT to prepare for a peer IPSI interchange. This test checks the operation of setting up a Peer Link, and verifies that the active and standby IPSI's Packet Interface modules can communicate over the packet bus.

This test checks the functionality of both the active and standby Packet Interface modules, but it is run only on the standby Packet Interface module.

This test runs on [PKT-INT \(Packet Interface\)](#).

## Packet Interface Reset Test (#889)

The reset action initializes the Packet Interface firmware on the IPSI circuit pack and runs a comprehensive set of diagnostic tests.

The demand reset action aborts if the specified IPSI circuit pack's Packet Interface module is in the active in-service state.

An IPSI circuit pack's Packet Interface module is put in the out-of-service state automatically if it resets 3 times by background maintenance within the last 15 minutes, independent of the results of the reset action.

If the Packet Interface module is on the standby IPSI ([S8700-series Fiber-PNC](#); and this is a high- or critical-reliability system), the demand reset action runs, independent of the service state.

This test runs on [PKT-INT \(Packet Interface\)](#).

## Signaling Port LAN Loopback Test (#939)

**This test is destructive.**

This test verifies the connectivity of an ISDN-PRI signaling port (D-channel) across the packet bus, also known as the LAN bus. It will run only if the port is out of service. Failure of this test indicates a fault associated with the port hardware on the circuit pack.

This test runs on [ISDN-PLK \(ISDN-PRI Signaling Link Port\)](#).

**Table 464: Signaling Port LAN Loopback Test (#939) 1 of 2**

| Error Code | Test Result | Description / Recommendation                                                                                                                                                                                                                                                                                                                                                                                                 |

## Failure Audit Test (#949)

This test queries the DS1 converter circuit pack for any existing circuit pack or facility failures and any unacknowledged cleared failure messages.

This test runs on [DS1C-BD \(DS1 Converter Circuit Pack\)](#) and [DS1-FAC \(DS1 Facility\)](#).

**Table 465: Failure Audit Test (#949)**

| Error Code                   | Test Result | Description / Recommendation                                                                                                                                                                                                                                                                                                             |

---

## PN Cold Restart Test (#955)

PN Cold Restart, or PN Reset Level 2, is used as an error recovery mechanism for a PN that has been taken out of service. Once a PN has gone out of service, a PN Cold Restart is required to bring it back into service.

When a PN is taken out of service, all originating and terminating calls on the affected PN are dropped and new phone calls cannot be made. During the restart, all hardware on the affected PN will be re-initialized. The restart takes no longer than 2 minutes.

When the link has been down for 60 seconds, the PN is taken out of service. When the link comes up, a PN cold restart will occur automatically. See [PN Warm Restart Test \(#956\)](#).

## Maintenance Demand Tests

A PN Cold Restart can be invoked on demand with `reset port-network P level 2`

**Table 466: PN Cold Restart Test (#955)**

| Error Code           | Test Result | Description / Recommendation                                                                                                                                                                                                                                                                    |

## PN Warm Restart Test (#956)

The PN Warm Restart, or PN Reset Level 1, restarts a PN that has not been taken out of service. It is the least severe of the PN restart levels and is used in an attempt to preserve the state of the system as much as possible to reduce user impact.

When the link goes down, the port network becomes unavailable. Current calls are preserved, but users on the affected PN are not able to place or receive new phone calls.

If the link comes up in less than 60 seconds, a warm restart is performed automatically.

If the link does not come back up within 60 seconds, the PN is placed in the out-of-service state. When the link does come back up, the PN will require a cold restart. See [PN Cold Restart Test \(#955\)](#)

A PN Warm Restart can be invoked on demand with `reset port-network P level 1`

**Table 467: PN Warm Restart Test (#956) 1 of 2**

| Error Code    | Test Result | Description / Recommendation                                                                                                                                                                                                                                                                                                                                                                |

## Analog Port Sanity Test (#963)

This test verifies that the port circuitry involved in the analog trunk testing on the Maintenance/Test analog port is functioning properly.

This test will abort if an ATMS test call is in progress on the Maintenance/Test analog port when the test is requested.

This test runs on [M/T-ANL \(Maintenance/Test Analog Port\)](#).

**Table 468: Analog Port Sanity Test (#963)**

## SNI Sanity Timer Test (#964)

The SNI Sanity Timer Test checks the number of times the sanity timer has expired. If the sanity timer expires twice within one second, the SNI will lock up and port networks will go down. The test passes if there are no sanity timer expirations. The test fails if it detects that the SNI has missed sanity. This test runs on [SNI-BD \(SNI Circuit Pack\)](#).

**Table 469: SNI Sanity Timer Test (#964) 1 of 2**

## SNI Fiber Out of Frame Query Test (#989)

This test performs a non-destructive facility test of the SNI. The SNI circuit pack reports whether a fiber out of frame condition exists, whether a loss of signal condition exists, and whether the lightwave transceiver is present.

This test runs on the following maintenance objects:

- | [FIBER-LK \(Fiber Link\)](#)
- | [SNI-BD \(SNI Circuit Pack\)](#)
- | [SNI-PEER \(SNI Peer Link\)](#)

**Table 471: SNI Fiber Out of Frame Query Test (#989) 1 of 7**

## VC Summer Port Local TDM Looparound Test (#1100)

**This test is destructive.**

This test verifies the connectivity of a VC Summer Port across the TDM bus. It aborts if calls associated with the port are in progress. Failure of this test indicates an on-board fault associated with the port hardware on the circuit pack. The Loopback test runs the following tests:

- 1 A Looparound test across the TDM bus.
- 1 A conference circuit test.

The tests are run in the above order. If the first test fails, an Error Code is returned and the second test is not executed. The test is run on [VC-SUMPT \(Voice Conditioner Summer Port\)](#)

## VC DSP Port NPE Crosstalk Test (#1103)

### This test is destructive.

The VC DSP Port NPE Crosstalk Test verifies that this port's Network Processor Element (NPE) channel talks on the selected time slot and never crosses over to time slots reserved for other connections. If the NPE is not working correctly, one-way and noisy connections may be observed. This test is part of the port's long test sequence and takes approximately 20 to 30 seconds to complete.

This test runs on [VC-DSPPT \(Voice Conditioner DSP Port\)](#).

## VC DSP Port Local TDM Loopback Test (#1104)

**This test is destructive.**

This test verifies the connectivity of a VC DSP Port across the TDM bus. It aborts if calls associated with the port are in progress. Failure of this test indicates an on-board fault associated with the port hardware on the circuit pack. The Loopback Test runs a looparound test across the TDM bus, and a conference circuit test.

The tests are run in the listed order. If one test fails, an Error Code is returned and the remaining tests in the sequence are not executed. This test runs on [VC-DSPPT \(Voice Conditioner DSP Port\)](#).

## VC Port Reset DSP Test (#1106)

**This test is destructive.**

This test resets the VC DSP port and the DSP associated with it. As part of the reset procedure, the VC DSP port runs a series of self-tests on the hardware. If these self-tests fail, the test fails. Otherwise, the test passes.

Before executing the test, the VC DSP port must be busied out by entering **busyout port location**. After the completion of the test, the VC DSP port must be released by entering **release port location**.

This test runs on [VC-DSPPT \(Voice Conditioner DSP Port\)](#).

**Table 476: VC Port Reset DSP Test (#1106) 1 of 2**

| Error Code   | Test Result | Description / Recommendation                                                                                                                                                             |

---

## TSI Looparound Test (#1108)

During this test, the MMI's Time Slot Interchanger (TSI) listens to a TDM timeslot. A digital count tone loops back in the TSI and onto another TDM timeslot without passing through any resource hardware. A tone detector port verifies the looped data. If the digital count is correct, then the test passes. The test is done for both TDM buses. Failures indicate that the TSI is unreliable.

This test is run on [MMI-BD \(Multimedia Interface Circuit Pack\)](#).

Table 477: TSI Looparound Test (#1108) 1 of 2

| Error Code | Test Result | Description / Recommendation                                                                                   |

## Resource Looparound Test (#1111)

**This test is destructive.**

This test checks the connectivity of the resource within an MMI circuit pack and out to the TDM bus. It tests the circuitry that an H.221 bit stream comes in contact with when the stream is demultiplexed, pre-processed, written to the TDM bus and then reread (looped in the TSI), post-processed, multiplexed, and then written back to the TDM bus for verification. The video, audio, and data components of the bit stream are tested separately. If any one of these tests fails, the resource is taken out of service.

This test is run on [MMI-PT \(Multimedia Interface Port\)](#).

## MMI Synchronization Status Test (#1122)

To support applications involving multiple MMI circuit packs, the appropriate MMI circuit packs must be synchronized with one another. One such circuit pack is designated as the master sync source, which provides the synchronization signal onto the TDM bus. The other MMI circuit packs in the system listen to this signal.

This test monitors this synchronization state. The test fails if the MMI circuit pack is not in sync. The test passes with auxiliary code 1100 if the MMI circuit pack is in sync and is providing the synchronization signal for the system. The test also passes with an auxiliary code of 1101 if the MMI circuit pack is in sync and listening to the sync signal. MMI circuit packs do not lose the synchronization signal unless an MMI circuit pack is either pulled out of the system or reset by using a technician command.

Test #1122 runs when `test board location long` is entered, initiating the recovery of synchronization. Use the `long` option only if synchronization is not established within 5 minutes of investigating the problem.

This test is run on [MMI-BD \(Multimedia Interface Circuit Pack\)](#).

## Digital Terminal Remote Looparound Test (#1201)

This test checks the connection between the server and the digital terminal. It verifies the ability of the terminal and the associated port to send and receive data. This test is based on procedure 622 to isolate digital terminal problems.

## Maintenance Demand Tests

This test runs on [DIG-LINE \(Digital Line\)](#).

## DS1 Board Loopback Test (#1209)

**This test is destructive.**

The DS1 BLB (Board Loopback) Test causes a loopback at the DS1 board edge and tests DS1 board internal circuitry.

This test is destructive and can only be initiated by entering the command `test ds1-loop location ds1/csu-loopback-test`.

All trunks or ports on the DS1 Interface circuit pack must be busied out using `busyout board` before running the BLB test.

When the BLB test is initiated, maintenance software sends a message to the DS1 Interface circuit pack. The board sets up the BLB loopback, transmits a test pattern, and verifies that the pattern is received unaltered through the loopback. If the transmitted and received patterns are different, the test fails.

When the test is complete, enter **release board** to restore all trunks or ports on the DS1 Interface circuit pack to the in-service state.

This test is run on the following maintenance objects:

- | [DS1-BD \(DS1 Interface Circuit Pack\)](#)
- | [MG-DS1 \(DS1 Interface Media Module\)](#)
- | [UDS1-BD \(UDS1 Interface Circuit Pack\)](#)

## CSU Equipment Loopback Test (#1210)

**This test is destructive.**

For documentation purposes, the term *DS1* applies to the following:

- DS1 Interface circuit packs
- DS1 Interface media modules
- UDS1 circuit packs.

The CSU ELB (Equipment Loopback) test causes a loopback at the near-edge of the local 120A CSU module or T1 sync splitter, and tests the connection from the DS1 board to the CSU module/T1 sync splitter (DS1 board edge interconnecting cable, and CSU module/T1 sync splitter edge). This test will only be performed if the 120A CSU module/T1 sync splitter is present, administered, and connected to a 1.544-Mbps DS1 circuit pack on the back of the port carrier.

The test is destructive and can only be initiated by entering the command `test ds1-loop location ds1/csu-loopback-tests`.

Enter `busyout board` to busy out all trunks or ports on the DS1 Interface circuit pack before running the ELB test.

When the ELB test is initiated, maintenance software sends a message to the DS1 Interface circuit pack to start the test. The board sets up the ELB loopback, transmits a test pattern, and verifies that the pattern is received unaltered through the loopback. If the transmitted and received pattern is different, the test fails.

The DS1 circuit pack hardware applies a DC current while the test is running in order to detect any broken wires that may not be detected by the loopback pattern.

When the test is complete, enter `release board` to restore all trunks or ports on the DS1 Interface circuit pack to the in-service state.

This test is run on the [DS1-BD \(DS1 Interface Circuit Pack\)](#) and [UDS1-BD \(UDS1 Interface Circuit Pack\)](#) maintenance objects.

## CSU Repeater Loopback Test (#1211)

**This test is destructive.**

For documentation purposes, the term *DS1* applies to the following:

- DS1 Interface circuit packs
- DS1 Interface media modules
- UDS1 circuit packs.

## Maintenance Demand Tests

The CSU RLB (Repeater Loopback) test causes a loopback at the far-edge of the local 120A CSU module or T1 sync splitter, and tests the connection from the DS1 board to and including the CSU module/T1 sync splitter circuitry. The test runs only if the 120A CSU module/T1 sync splitter is present, administered, and connected to a 1.544-Mbps DS1 circuit pack on the back of the port carrier.

The test is destructive and can only be initiated by entering the command `test ds1-loop location ds1/csu-loopback-test`.

Enter `busyout board` to busy out all trunks or ports on the DS1 Interface circuit pack before running the RLB test.

When the RLB test is initiated, maintenance software sends a message to the DS1 Interface circuit pack to start the test. The board sets up the RLB loopback, transmits a test pattern, and verifies that the pattern is received unaltered through the loopback. If the transmitted and received pattern is different, the test fails.

The DS1 circuit pack hardware applies a DC current while the test is running in order to detect any broken wires that may not be detected by the loopback pattern.

When the test is complete, use `release board` to restore all trunks or ports on the DS1 Interface circuit pack to the in-service state.

This test is run on the [DS1-BD \(DS1 Interface Circuit Pack\)](#) and [UDS1-BD \(UDS1 Interface Circuit Pack\)](#) maintenance objects.

## CPE Loopback Jack Test (#1212)

**This test is destructive.**

For documentation purposes, the term *DS1* applies to the following:

- DS1 Interface circuit packs
- DS1 Interface media modules
- UDS1 circuit packs.

The CPE Loopback Jack (CLJ-LB) test causes a loopback at the CPE loopback jack and tests the building wiring connection between the DS1 board and the CPE loopback jack.

The test is highly destructive and can only be initiated by entering the command `test ds1-loop location cpe-loopback-jack-test-begin [number-of-bits bit-pattern]`. Enter a loopback activation code on the command line or use the default code (0x47F).

Enter `busyout board` to busy out all trunks or ports on the DS1 Interface circuit pack before running the CPE Loopback Jack test.

The CPE Loopback Jack test has the DS1 Interface circuit pack transmit a loopback activation code to the CPE loopback jack, waits up to 10 seconds for return of the code to verify the loopback has been established, transmits a framed 3-in-24 test pattern, begins counting bit errors in the received test pattern, and returns a PASS result to indicate that the pattern was successfully sent. If the loopback is not established within the 10 seconds, the test returns FAIL.

The status of the CPE Loopback Jack test appears in the error log as Error Type 3900. Several distinct aux values give information on the status of the test.

Enter `list measurements ds1 summary` to show the length of time the test has been running (`Test Duration` field) and number of bit errors detected (`Loopback/Span Test Bit-Error Count` field). If the test pattern is passed through the loopback cleanly, the number of bit errors should be very low. The command also shows the type of loopback/span test executing (`Test` field), the type of pattern generated for the loopback/span test (`Pattern` field), and whether the pattern (*3-in-24 Pattern*) is synchronized (`Synchronized` field).

Enter `test ds1-loop location end-loopback/span-test` to end the test.

Enter `release board location` to restore each trunk or port on the DS1 Interface board to the in-service state.

This test is run on the following maintenance objects:

- 1 [DS1-BD \(DS1 Interface Circuit Pack\)](#)
- 1 [MG-DS1 \(DS1 Interface Media Module\)](#)
- 1 [UDS1-BD \(UDS1 Interface Circuit Pack\)](#)

## Far CSU Loopback Test (#1213)

**This test is destructive.**

For documentation purposes, the term *DS1* applies to the following:

- DS1 Interface circuit packs
- DS1 Interface media modules
- UDS1 circuit packs.

The Far CSU Loopback (R-LLB) test causes a loopback at the far-end CSU, and tests all circuitry and facilities from the local DS1 board to the far-end CSU.

The test is destructive and can only be initiated by entering the command `test ds1-loop location far-csu-loopback-test-begin`.

## Maintenance Demand Tests

Enter **busyout board** to busy out all trunks or ports on the DS1 Interface circuit pack before running the Far CSU Loopback test.

If the DS1 is administered for ami-zcs line coding and the far-end CSU is not a 120A CSU module or a 401A T1 sync splitter, density protection on the CSU must be disabled during the test due to the large number of zero's in the 3-in-24 test pattern.

The Far CSU Loopback test has the DS1 Interface circuit pack transmit a loopback activation code to the remote CSU, waits up to 15 seconds for return of the code to verify the loopback has been established, transmits a framed 3-in-24 test pattern, begins counting bit errors in the received test pattern, and returns a PASS result. If the loopback is not established within the 15 seconds, the test fails.

The status of the Far CSU Loopback test appears in the error log as Error Type 3901. Several aux values give information on the status of the test.

Enter **list measurements ds1 summary** to show the length of time the test has been running (`Test Duration` field) and number of bit errors detected (`Loopback/Span Test Bit-Error Count` field). If the test pattern is passed through the loopback cleanly, the number of bit errors should be very low. The command also shows the type of loopback/span test executing (`Test` field), the type of pattern generated for the loopback/span test (`Pattern` field), and whether the pattern (*i.e.*, *3-in-24 Pattern*) is synchronized (`Synchronized` field).

Enter **test ds1-loop location end-loopback/span-test** to end the test.

Enter **release board location** to restore all trunks or ports on the DS1 Interface circuit pack to the in-service state.

This test is run on the [DS1-BD \(DS1 Interface Circuit Pack\)](#) and [UDS1-BD \(UDS1 Interface Circuit Pack\)](#) maintenance objects.

## One-Way Span Test (#1214)

**This test is destructive.**

For documentation purposes, the term *DS1* applies to the following:

- DS1 Interface circuit packs
- DS1 Interface media modules
- UDS1 circuit packs.

The One-Way Span test allows 1-way span testing to and from remote test equipment or another Communication Manager solution. This tests all circuitry and facilities from the local DS1 board to the remote test equipment or other Communication Manager solution.

The test is destructive and can only be initiated by entering the command `test ds1-loop location one-way-span-test-begin`.

Enter `busyout board` to busy out all trunks or ports on the DS1 Interface circuit pack before running the One-Way Span test.

The One-Way Span test has the DS1 Interface circuit pack transmit a framed 3-in-24 test pattern and attempts to receive and verify the pattern. If the DS1 board receives a framed 3-in-24 test pattern sent from another Communication Manager system or test equipment at the far end of the DS1, it begins counting bit errors within the received pattern.

**Note:**

If a DS1 circuit pack and a DS1 Interface media module are connected, the test will fail because the media module does not frame-align its test pattern.

The status of the One-Way Span test appears in the error log as Error Type 3902. Several aux values give information on the status of the test.

Enter `list measurements ds1 summary` to see the length of time the test has been running (`Test Duration` field) and number of bit errors detected (`Loopback/Span Test Bit-Error Count` field). If the test pattern is sent cleanly over the span from the far end, the number of bit errors should be very low. The `Test Duration` field is `0` until the test pattern is received from the far end. Upon receiving the test pattern, the board begins calculating the test duration and number of bit errors. The command also shows the type of loopback/span test executing (`Test` field), the type of pattern generated for the loopback/span test (`Pattern` field), and whether the pattern (*i.e.*, `3-in-24 Pattern`) is synchronized (`Synchronized` field).

Enter `test ds1-loop location end-loopback/span-test` or `release board` to end the test. Enter `release board` to restore all trunks or ports on the DS1 Interface circuit pack to the in-service state

This test is run on the [DS1-BD \(DS1 Interface Circuit Pack\)](#) and [UDS1-BD \(UDS1 Interface Circuit Pack\)](#) maintenance objects.

## Inject Single Bit Error Test (#1215)

**This test is destructive.**

For documentation purposes, the term *DS1* applies to the following:

- DS1 Interface circuit packs
- DS1 Interface media modules
- UDS1 circuit packs.

The Inject Single Bit Error test causes a single bit error to be sent within an active framed 3-in-24 test pattern.

The test is highly destructive and can only be initiated by entering the command `test ds1-loop location inject-single-bit-error`. An attempt to use this command is rejected if none of the three long-duration DS1 loopback/span tests (CPE Loopback Jack test, Far CSU Loopback test, One-Way Span test) are active on a ds1 circuit pack.

Enter `busyout board` to busy out all trunks or ports on the DS1 Interface circuit pack before running the Inject Single Bit Error test.

Enter `list measurements ds1 summary` to show the number of bit errors detected (Loopback/Span Test Bit-Error Count field). Injecting this single bit error should increment the bit error count of the loopback/span test by one.

Enter `release board` to restore the trunks or ports on the DS1 Interface circuit pack to the in-service state.

## Maintenance Demand Tests

This test is run on the [DS1-BD \(DS1 Interface Circuit Pack\)](#) and [UDS1-BD \(UDS1 Interface Circuit Pack\)](#) maintenance objects.

## End Loopback/Span Test (#1216)

**This test is destructive.**

For documentation purposes, the term *DS1* applies to the following:

- DS1 Interface circuit packs
- DS1 Interface media modules
- UDS1 circuit packs.

The End Loopback/Span test deactivates an active loopback or span test on a DS1 circuit pack. Bit error counting against the received test pattern stream halts, and sending of the framed 3-in-24 test pattern ceases. If either the CPE loopback jack or the far-end CSU is looped, the loopback deactivate code is sent. If the loopback could not be deactivated, the test will FAIL and a MINOR alarm is noted in the alarm log until the loopback is cleared.

The test is highly destructive and can only be initiated by entering the command `test ds1-loop location end-loopback/span-test`. Since only one of these three different long-duration loopback/span tests can be active at a time, the DS1 circuit pack knows which loopback/span test to halt.

Enter `busyout board` to busy out all trunks or ports on the DS1 Interface circuit pack before running this End Loopback/Span test.

Enter `list measurements ds1 summary` to show the length of time the test ran (Test Duration field) and number of bit errors detected (Loopback/Span Test Bit-Error Count field).

Enter `release board` to restore the trunks or ports on the DS1 Interface circuit pack to the in-service state.

This test runs on [DS1-BD \(DS1 Interface Circuit Pack\)](#) and [UDS1-BD \(UDS1 Interface Circuit Pack\)](#).

## ICSU Status LEDs Test (#1227)

This test runs only on TN767E or later DS1 circuit packs and TN464F or later UDS1 circuit packs administered for 24-channel operation (1.544 Mbps).

The DS1 circuit pack has four status LEDs on the faceplate in addition to the three standard faceplate LEDs. These four status LEDs are associated with the 120A channel Service Unit (CSU) Module that can be connected to the DS1 board via the I/O connector panel on the back of the port carrier.

This test is a visual test. It lights the four status LEDs red for 5 seconds, green for 5 seconds, and yellow for 5 seconds. It then turns the LEDs off and returns control of the status LEDs to the circuit pack. The interpretation of the LEDs are described in the DS1/UDS1 (TN767/TN464) section in the *LED Descriptions for Avaya Aura™ Communication Manager Hardware Components (03-602804)*

The DS1 circuit pack, combined with the 120A CSU module or the 401A T1 sync splitter, forms an Integrated CSU (ICSU).

If the 120A CSU module/T1 sync splitter is not installed, the status LEDs are always off and this test aborts.

This test is run on the following maintenance objects:

- | [DS1-BD \(DS1 Interface Circuit Pack\)](#)
- | [MG-DS1 \(DS1 Interface Media Module\)](#)
- | [UDS1-BD \(UDS1 Interface Circuit Pack\)](#)

## Trunk-side Layer 1 Query Test (#1242)

This test determines the state of the transmission facility of a BRI port at the Layer 1 (L1) physical layer: Activated, Pending Activation, or Deactivated.

The Activated state is the correct state for an ISDN-BRI port. In this state, the L1 interface can send and receive synchronized signals. This test passes if the state of L1 is Activated. This test also passes if software has taken this port out of service. See the description of the L1 "Deactivated State" below for more details.

The Pending Activation state indicates a problem with the channels, the wiring, or the TBRI-BD circuit pack. When in this state, the Level 1 interface is either not receiving any L1 framing from the channel or it is communicating with the channel but cot transition to the Activated state.

The Deactivated state indicates a problem with the TBRI-BD circuit pack. When in this state, the Level 1 interface is not active, an idle signal is transmitted to the channels, or that Layer 1 was deactivated by the switch. When a TBRI-PT port is placed in the out-of-service state, Level 1 is also put into the Deactivated state. This could be due either to the system detecting a fault with the port or to a *busyout port location* request.

This test is run on [TBRI-PT \(ISDN Trunk-Side BRI Port\)](#).

## BRI Layer 3 Query Test (#1243)

This test checks the application layer communications across the in-service ISDN D-channel. The test passes if a status inquiry message is successfully sent, fails if the signaling link is down, and aborts if a query is already running or there is an internal error.

## Maintenance Demand Tests

This test runs on [TBRI-PT \(ISDN Trunk-Side BRI Port\)](#).

**Table 492: BRI Layer 3 Query Test (#1243)**

| Error Code   | Test Result   | Description / Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                    |

## BRI Port Slip Query Test (#1244)

Slips occur when the transmitter and receiver are not running at precisely the same clock rate. The BRI Slip Query Test polls the total number of slips that have occurred on a link.

If the slip count is over the threshold, a MINOR alarm is raised against the circuit pack, leaving every port of the circuit pack in the in-service state.

TN2185 only: If the TN2185 circuit pack is supplying the system synchronization source, the MINOR alarm will initiate a synchronization source switch. See [TDM-BUS \(TDM Bus\)](#) and [SYNC \(Port Network Synchronization\)](#) for additional information.

This test runs on [TBRI-PT \(ISDN Trunk-Side BRI Port\)](#).

## Signaling Link State Test (#1251)

This test checks the current state of the signaling link. The test looks at the board-level translations, checks that the board is physically inserted, then gets the state of the D-channel and service state of the port.

The test passes if the signaling link (D-channel) is connected and operating normally. The test fails if the board is not installed, the signaling link is disconnected, or if the port is out of service. The test aborts otherwise.

This test runs on [TBRI-TRK \(ISDN Trunk-Side BRI Channel\)](#).

**Table 494: Signaling Link State Test (#1251) 1 of 2**

## ATM Board Reset (#1256)

**This test is destructive.**

This test runs on ATM-EI and ATM-TRK circuit packs. It is only executed as part of the `reset board location` command. The board must first be busied out in order to run this test.

This test runs on the [ATM-EI \(Expansion Interface Circuit Pack\)](#) and [ATM-TRK \(Circuit Emulation Service Circuit Pack\)](#) maintenance objects.

**ATM-EI:** If the ATM-EI board is a standby in a PN, the reset is done through the SAKI reset interface. If the ATM-EI is an Expansion Archangel (active ATM-EI board in the PN) and if the EAL is present, a special message is sent to the board over the EAL.

**ATM-TRK:** This test checks the sanity of the Angel processor using the Sanity and Control Interface (SAKI) test (#53). It resets the circuit pack if the SAKI test fails and runs the test again. The ATM Board Reset test passes if SAKI can successfully reset the board.

Before running the SAKI test on an ATM-TRK circuit pack, you must:

- 1 Move synchronization off the ATM-TRK circuit pack
- 1 Busyout the ATM-TRK circuit pack

The test aborts if the ATM-TRK circuit pack is supplying synchronization.

Table 495: ATM Board Reset (#1256) 1 of 2

| Error Code | Test Result | Description / Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                       |

---

## ATM Board Error Query Test (#1259)

This test queries the board for its on-board health information. The test passes if there are no failures on the board. The test fails if the circuit pack has hardware or signaling failures.

## Maintenance Demand Tests

This test runs on [ATM-EI \(Expansion Interface Circuit Pack\)](#), and [ATM-TRK \(Circuit Emulation Service Circuit Pack\)](#).

**Table 496: ATM Board Error Query Test (#1259)**

| Error Code | Test Result | Description / Recommendation                                                                                                                                                                                                                                                                                                                                          |

## ATM Board Framer Looparound Test (#1260)

This test is destructive.

**Note:**

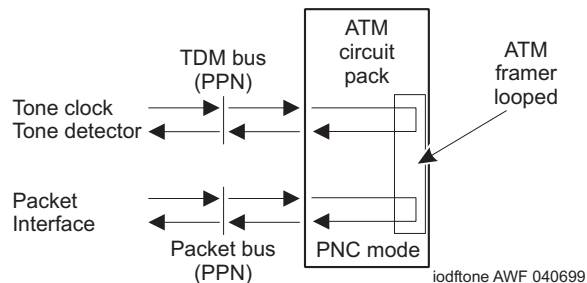

This test requires the board to be busied out. In a duplex system, this test can be run on the standby ATM-EIs. In a simplex system, this test can be run only on the ATM EI boards in the PPN.

This test places the ATM circuit pack in ATM framer looparound mode. It verifies the board's circuit and packet paths. This test verifies both the TDM path and the Packet Path. If the TDM test path passes, then the packet path is tested.

Definitions of each test path are:

- 1 **Circuit (TDM) path:** one of the Tone Generators sends a bit pattern through a TDM bus time slot to the ATM framer. The pattern is converted into ATM cells and is looped back to the ATM-EI board, which converts the cell back into the bit pattern and puts it on a pre-determined time slot. A Tone Detector tests for the bit pattern and reports the test result. This test verifies that a large portion of the ATM-EIs circuit paths are functioning correctly. [Figure 114: ATM Board Framer Looparound Test \(#1260\)](#) shows a diagram of the test.

**Figure 114: ATM Board Framer Looparound Test (#1260)**

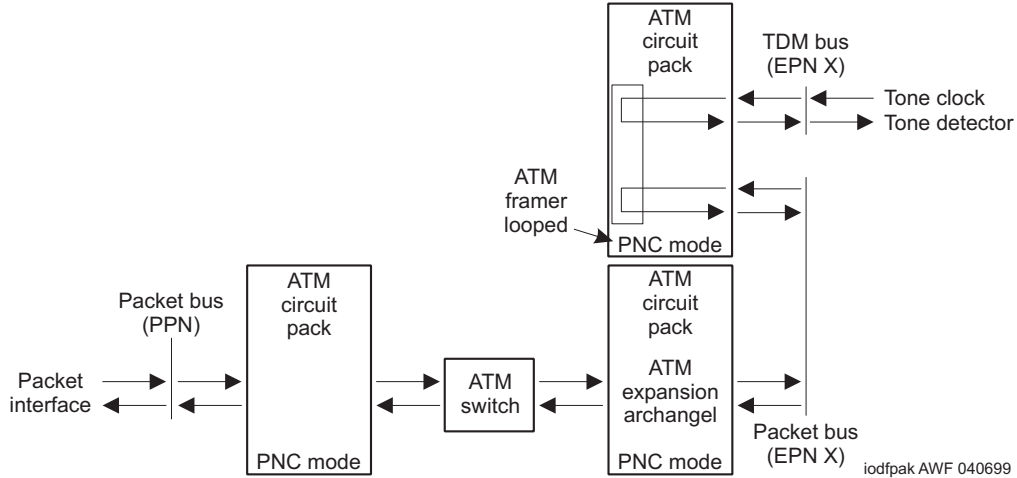

- 1 **Packet path:** the Packet Interface circuit pack sends packet data to the ATM framer interface, where it is mapped into ATM cells and then looped around internally. The cells are converted back to packet data after it has been looped. This portion of the test verifies correct operation of the ATM-EI's packet bus interface and a large portion of the ATM-EI's packet paths. [Figure 115: ATM Board Framer Looparound Test \(#1260\) \(non-EAA, Packet Path\)](#) shows the packet switched signal path for the ATM circuit pack.

This test verifies the operation of a large portion of the ATM-EI circuit and packet paths, but does not verify the optical portion of the lightwave transceiver. If this test passes, the ATM-EI circuit pack is functioning correctly, but faults can exist in the lightwave transceiver. If the test fails, the fault can be on the board.

**Maintenance Demand Tests**

This test runs on [ATM-EI \(Expansion Interface Circuit Pack\)](#) and [ATM-TRK \(Circuit Emulation Service Circuit Pack\)](#).

## ATM Board Time Of Day Update (#1261)

The ATM circuit pack requires a reference time for SDH/SONET performance monitoring. This test sends the system time to the board to set the time of day. The update synchronizes the board with the system's clock. This test runs on [ATM-EI \(Expansion Interface Circuit Pack\)](#), [ATM-TRK \(Circuit Emulation Service Circuit Pack\)](#).

**Table 500: ATM Board Time Of Day Update (#1261)**

## SCOTCH Synchronous Looparound Test (#1275)

**This test is destructive.**

This test verifies the circuit in the data path of a C-LAN PPP call or VAL announcement port call. This test fails if the data transmitted on the port does not match the data received in the looparound mode. Failure of this test indicates a port hardware fault on the circuit pack.

This test aborts if calls are using the port, or if the PPP or VAL link associated with the port is connected. To avoid this, first enter `busyout data-module extension`, or `busyout port location`, or `busyout link link#`, which will cause every call and link using the port to be torn down.

## Maintenance Demand Tests

This test runs on [PPP-PT \(Control LAN Packet/Port\)](#) and [VAL-PT \(Voice Announcements over LAN Packet/Port\)](#).

**Table 501: SCOTCH Synchronous Looparound Test (#1275)**

## TCP/IP Ping Test (#1281)

The TCP/IP Ping Test checks the circuitry involved in the data path of a peer-peer IP layer connection. The test passes if at least one endpoint responds to the ping request. The test fails if all endpoints fail to respond.

This test is executed for C-LAN ports administered as PPP or Ethernet ports. It runs on [ETH-PT \(Control LAN Ethernet\)](#) and [PPP-PT \(Control LAN Packet/Port\)](#).

## Link Integrity Inquiry Test (#1282)

This test checks the link integrity of the TN799 C-LAN Ethernet port's physical connections. It runs on [ETH-PT \(Control LAN Ethernet\)](#).

**Table 505: Link Integrity Inquiry Test (#1282) 1 of 2**

## TDM Looparound Test (#1285)

### This test is destructive.

This test verifies whether the VAL or C-LAN port can send and receive data on the TDM bus. This test requests a tone generator to send tones on a timeslot and a tone receiver to receive tones on another timeslot. The tones are looped through the PPP port. The test passes if the received tones match the tones that were sent. The test fails if the tones do not match.

A test failure indicates failure of one or more of the following components:

- 1 C-LAN (TN799DP) circuit pack
- 1 VAL (TN2501) circuit pack
- 1 TDM bus
- 1 Tone generator / tone receiver circuit pack

This test runs on [PPP-PT \(Control LAN Packet/Port\)](#) and [VAL-PT \(Voice Announcements over LAN Packet/Port\)](#).

## Session Status Test (#1286)

This test queries the status of every Ethernet or PPP port session. It runs on [ETH-PT \(Control LAN Ethernet\)](#) and [PPP-PT \(Control LAN Packet/Port\)](#).

| If the system indicates that...       | Then the test...                  |
|---------------------------------------|-----------------------------------|
| Every port session is up (ALL UP)     | Raises no alarm, or retires alarm |
| Some port sessions are up (SOME UP)   | Raises a WARNING alarm            |
| Every port session is down (ALL DOWN) | Raises a MINOR alarm              |

## ATM Remote Layer 3 Query (#1291)

The ATM Remote Layer 3 Query Test queries the far-end switch or terminal adapter to determine whether the signaling connection is functioning properly at Layer 3. It selects a B-channel in the in-service or maintenance service state and sends an ISDN Layer-3 SERVICE message, which requires a response from the far end. The test is not performed if there are no B-channels in an appropriate ISDN service state (for example, when none are administered or they are all out of service).

**Note:**

The service state can be displayed by using the `status trunk grp#/mem#` or `status pri-endpoint` command.

A PASS only indicates that a message was successfully sent to the far-end switch or terminal adapter. The ISDN PRI Specification allows up to 2 minutes for a response. Check the Error Log for ATM-SGRP errors of type 2305 for evidence of an ATM Remote Layer 3 Query failure.

This test checks the communication path from the processor, through the TDM/packet bus and ATM Interface circuit pack, and on to the far-end switch or terminal adapter. It is designed to ensure that the communication path between the switch and the far end is up and operational, and that the two endpoints can properly exchange ISDN control messages.

This test runs on [ATM-SGRP \(ATM Signaling Group\)](#).

## ATM Board DSP Test (#1293)

This test checks the board's interface to the TDM bus and the functions of all 24 on-board DSPs (Digital Signal Processors). There are three functional types of DSPs:

- 1 talkers – put data on the TDM bus
- 1 listeners – take data off the TDM bus
- 1 echo cancellers – filter out echoes of the main transmission

If the test fails for every DSP, a MAJOR alarm is raised against the board.

If the test fails for one or more DSPs, a MINOR alarm is raised.

If a DSP is busy, the test for that particular DSP is considered passed.

## Maintenance Demand Tests

The test aborts if the system resources such as TDM time slots and Tone Generator are not available.

This test applies to TN2305 and TN2306 ATM-EIs, both active and standby. It runs on [ATM-EI \(Expansion Interface Circuit Pack\)](#) and [ATM-TRK \(Circuit Emulation Service Circuit Pack\)](#).

## ATM Crosstalk Test (#1298)

The ATM Crosstalk Test verifies that TDM time slots are correctly allocated to connections. It is useful for diagnosing one-way or noisy connections. The test fails if the TDM programmable logic and/or the interface to the DSP is not operating properly.

This test runs on [ATM-EI \(Expansion Interface Circuit Pack\)](#) and [ATM-TRK \(Circuit Emulation Service Circuit Pack\)](#).

**Note:**

This test takes approximately 12 minutes and applies only to TN2305 and TN2306 circuit packs.

## RC NPE Port Audit Test (#1315)

This tests executes the NPE crosstalk test on a Radio controller (RC) NPE port. If the test is unsuccessful, the port number (1-24) of the RC NPE port which failed is returned.

Not all ports are tested, as this would take an excessive amount of time. It is most likely that if one port fails, then all of the ports are bad. To test all 24 RC NPE ports, use the *repeat 24* option for the `test board` command. This test is run on [RC-BD \(Radio Controller Board\)](#).

## RC NPE Port Loop Test (#1316)

The circuit pack must be busied out before running this test.

This test executes the NPE Digital Port Loop Test on a Radio controller (RC) NPE port. If the test is unsuccessful, the port number (1-24) of the RC NPE port which failed is returned.

## Maintenance Demand Tests

Not all ports are tested, as this would take an excessive amount of time. It is most likely that if one port fails, then all of the ports are bad. To test all 24 RC NPE ports, use the **repeat 24** option for the **test board** command. This test is run on [RC-BD \(Radio Controller Board\)](#).

**Table 512: RC NPE Port Loop Test (#1316)**

## RC Hardware Translation Audit (#1317)

This test validates that the operating parameters which are translated for an RC circuit pack match those that have been previously downloaded to the circuit pack.

If this audit fails, an error will be logged and a WARNING alarm generated. However, no attempt will be made to correct the mismatched data by re-downloading to the RC. Instead, the RC circuit pack needs to be reset to have the operating parameters re-downloaded to the circuit pack. The RC circuit pack cannot accept operating parameter updates and still remain in-service.

This test is run on [RC-BD \(Radio Controller Board\)](#).

## RC Tone Loopback Test (#1343)

This test is very disruptive.

The RC board must first be busied out in order for this test to run.

This test validates the RC board circuitry by looping a 1004 Hz reflective tone to the far-end of the RC circuit pack, then back to the processor. The Loopback Test is performed 24 times, once for each NPE port.

This test aborts if any of the 24 tone loopback tests abort. This test fails if any of the 24 tone loopback tests fail. If all 24 tone loopback tests pass, this test passes.

This test is run on [RC-BD \(Radio Controller Board\)](#).

## ASAI Link Status Test (#1365)

This tests queries the system for the state of the TCP Tunnel Connection and the ASAI TCP/IP link. If both the TCP Tunnel Connection and the ASAI TCP/IP Link are in the "established" state, the test passes. The test fails otherwise. This test is run on [ADJ-IP \(ASAI Adjunct TCP/IP Link\)](#).

**Table 516: ASAI Link Status Test (#1365)**

| Error Code | Test Result | Description / Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

## IP Address Update Test (#1371)

This test is **conditionally destructive**.

This test queries the media processor for its IP address, subnet mask, and gateway translation (IP parameters). If the parameters do not match software translation, the system reboots the board. The board goes through a logical board removal and insertion.

When Test #1371 fails, it is an indication that an illegal change was made and the customer should be notified.

This test sends the following information to the board:

- 1 IP address, subnet mask, gateway address, VLAN information, and ethernet options information from the **change ip-interface** form. If the board is one of a duplicated pair, the test also updates the board's virtual IP address and virtual MAC address.
- 1 QoS, Diffserv, and Audio DSP gains from the **change system-parameters ip-options** and **change ip-network-region** forms

This test also updates the board's packet link translation and checks if the packet link is in service for the board.

This test is run on [IPMEDPRO \(IP Media Processor\)](#) and [MEDPRO \(Media Processor MAPD Circuit Pack\)](#).

## Registration Status Inquiry Test (#1372)

The Registration status inquiry reports the H.323 registration status of the endpoint. An endpoint must be registered and authenticated in order to receive service from the system.

Registration is initiated when the endpoint user attempts to login using the Avaya registration software application running on the endpoint PC. The user must provide a valid extension and security code. The registration messages are sent to the IP address of a C-LAN Ethernet port.

A registered extension has a port type of SNNNNN, where N is a digit from 0–9. A non-registered extension has a port type of X.

This test runs on [DIG-IP-S \(Digital IP Station\)](#) and [H323-STN \(H.323 IP Station\)](#).

**Table 518: Registration Status Inquiry Test (#1372)**

## Signaling Path PING Test (#1373)

This test checks the circuitry involved in the data path of a peer-to-peer IP layer connection. The Signaling Path PING test determines the local C-LAN through which the signaling originates and the endpoint's IP address. It then requests the local C-LAN to execute a PING on the endpoint's address. If the PING is successful, the test passes. If the PING is not successful, the test fails.

**Note:**

Multiple failures of this test can take the IP Station out of service.

This test runs on [DIG-IP-S \(Digital IP Station\)](#) and [H323-STN \(H.323 IP Station\)](#).

**Table 519: Signaling Path PING Test (#1373)**

## Media Path PING Test (#1374)

The Media Path PING Test selects a Media Processor board. It then requests the local Media Processor to execute a PING on the endpoint address. If the PING is successful, the test passes. If the PING is not successful, the test fails.

The standard `ping` command can be executed using the Media Processor board address and endpoint IP address to see the actual round-trip delay.

This test checks the IP network connectivity needed for audio packets to be sent to the endpoint. It runs on [H323-SGR \(H.323 Signaling Group\)](#).

## Ping Test (#1379)

This test verifies that the IP Media Processor can communicate with other nodes on the LAN.

This test pings the gateway IP address as defined on the IP Interface screen. If the PING is successful, this test looks at the PING round-trip delay. If a round-trip delay of greater than 4 seconds is reported, a separate error is logged. Excessive round-trip delays do not take the IP Media Processor out of service.

This test runs on [IPMEDPRO \(IP Media Processor\)](#) and [MEDPRO \(Media Processor MAPD Circuit Pack\)](#).

The test can be executed with the standard `ping` command using the C-LAN board address and IP Media Processor IP address to see the actual round-trip delay. (See `ping` commands.)

## DSP Port TDM Looparound Test (#1380)

This test sets up a loopback path from the TDM bus out to the NIC edge of the Media Processor and back to the TDM bus. The loopback is established by setting up the outbound IP connection to send IP packets to the MedPro's own IP address. The tone generator places a test tone (440Hz) onto a timeslot. The timeslot is listened to by the Media Processor board. The tone is routed through the board's DSP farm, where it may undergo transcoding to G.723, etc. The tone is looped back at the Network interface and back through the board where it is converted back into standard PCM. The tone is placed onto a TDM timeslot and detected by a tone detector port. The test passes if 440Hz is reported by the tone detector

This test runs on [MEDPROPT \(MEDPRO DSP PORT\)](#).

## Windows 2000 Reset Test (#1381)

This test resets the TN802 MAPD circuit pack. The test is highly **destructive** and can be initiated only by a **reset board location** command on the TN802 circuit pack.

This test runs on [MEDPRO \(Media Processor MAPD Circuit Pack\)](#).

**Table 523: Windows 2000 Reset Test (#1381) 1 of 2**

| Error Code | Test Result | Description / Recommendation                                                                                                                |

---

## DSP Query Test (#1382)

When running on a TN802 Media Processor circuit pack, this test polls the circuit pack for the number of failed DSPs. If every DSP is functional, the test passes and the board is operating at maximum capacity. If any DSPs fail, the test fails and reports the number of failed DSPs. A failure of 3 or fewer DSPs does not result in an alarm. A failure of more than 3 and up to 8 DSPs results in a warning alarm. A failure of more than 8 DSPs results in a minor alarm. In all cases, except when every DSP fails, the MEDPROPT continues to provide reduced capacity

When running on a TN2302 or TN2602 IP Media Processor circuit pack, this test polls the circuit pack for the state of health of a specific DSP. If the DSP is bad, an error will be logged and the board will be polled again. If the circuit pack is still failing, the DSP will be taken out of service and a MINOR alarm will be raised.

## Maintenance Demand Tests

This test runs on [MEDPROPT \(MEDPRO DSP PORT\)](#).

**Table 524: DSP Query Test (#1382)**

| Error Code | Test Result | Description / Recommendation                                                                                                     |

## C-LAN Ethernet Port Status Test (#1386)

This test checks the status of the C-LAN Ethernet port that is the near-end gatekeeper of this signaling group. If the C-LAN Ethernet port is in service, the test passes. If the port is out of service, the test fails.

This test runs on [H323-SGR \(H.323 Signaling Group\)](#) and [SIP-SGRP \(SIP Signaling Group\)](#).

## Maintenance Demand Tests

**Note:**

Failure of this test will put the SIG-GRP in the OOS state.

**Table 526: C-LAN Ethernet Status Test (#1386) 1 of 2**

## Signaling Group Ping Test (#1387)

This test checks the circuitry involved in the data path of a peer-to-peer IP layer connection. It is only run for those signaling groups that have an administered far-end IP address. If the H.323 or SIP signaling group does not have an administered far-end IP address, the test will abort.

The test determines the local C-LAN through which the signaling originates, and the far-end terminating IP address. It then requests the local C-LAN to execute a PING on the far-end address. If the PING is successful, the test passes. If the ping is not successful, the test fails.

**Note:**

Multiple failures of this test will cause this signaling group's associated H.323 or SIP B-channels to be taken out of service (OOSFE). This will allow incoming calls to be made when the far-end comes up before the near end has detected it. The signaling group will be left in service, but in the far end bypass state.

If the PING is successful, the test looks at the PING round-trip delay. If a round-trip delay of greater than 4 seconds is reported, a separate error is logged. Excessive round-trip delays within the signaling group will not take the signaling group out of service.

The standard PING command can be executed using the C-LAN board's address and far-end IP address from the signaling group screen to see the actual round-trip delay.

This test runs on [H323-SGR \(H.323 Signaling Group\)](#) and [SIP-SGRP \(SIP Signaling Group\)](#).

## MedPro Status Test (#1392)

This test determines if at least one media processor port is in service and serves the same region as the C-LAN that the signaling group uses. If at least port one exists and is in service, the test passes. Otherwise, the test fails.

This test runs on [H323-SGR \(H.323 Signaling Group\)](#) and [SIP-SGRP \(SIP Signaling Group\)](#).

## Ethernet Hardware Query Test (#1405)

This test queries the circuit pack for the status of the Ethernet hardware on the board.

If the Ethernet hardware is bad, the board will indicate this. An error and alarm will be posted, and the DSPs will be taken out of service. The system then attempts to reset the Ethernet hardware. If the reset passes or the original test passes, the DSPs are placed into service, if necessary.

This test runs on [IPMEDPRO \(TN2602AP IP Media Resource 320\)](#).

Table 530: Ethernet Hardware Query Test (#1405) 1 of 2

| Error Code    | Test Result | Description / Recommendation                                                                                                                                                                                                                              |

## MP Diagnostic Test (#1406)

**This test is destructive.**

The MP Diagnostic Test runs the following diagnostic tests in the following order, but only if each successive test passes:

**DSP FPGA Query:** This test verifies the status of the FPGA device on the TN2302 circuit pack. If the device is bad, the system posts an error and alarm and takes out of service every DSP that is controlled by the one FPGA. The system then attempts to reset the FPGA. If the reset passes or the original test passes, the DSPs are placed back into service.

**Ethernet Query:** This test passes if the TN2302 hardware is functioning properly and the Ethernet port is connected. Otherwise, it fails.

**SCOTCH Sanity:** The SCOTCH device on a board communicates with switch software via the TDM bus for conferencing and gain adjustment by setting up connections on TDM bus time slots. If errors are reported from the board, the system takes the DSPs out of service and executes a circuit pack reset (SAKI Test #53)

This test runs on [IPMEDPRO \(TN2302 IP Media Processor\)](#).

**Table 531: MP Diagnostic Test (#1406)**

| Error Code   | Test Result | Description / Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                         |

## DSP Port Status Query Test (#1407)

This test queries the state of the DSP port. It runs on [MEDPROPT \(MEDPRO DSP PORT\)](#).

**Table 532: DSP Port Status Query Test (#1407)**

| Error Code | Test Result | Description / Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

## Firmware Download Test (#1413)

**This test is destructive.**

This test has two functions and can only be executed if there is a download schedule to verify or if there are FW-DWNLD errors to resolve and alarms to clear.

1. This test verifies that the information on the FIRMWARE DOWNLOAD screen is correct. It also verifies that the source board is of the correct type, the file to be downloaded is present on that source board, and the file is free of errors. In addition, it verifies that the target board code and suffix are correct. It also retrieves the new firmware vintage for the target board and populates the appropriate field in the firmware download table.
2. If this test is executed after a FIRMWARE DOWNLOAD schedule has run and there are FW-DWNLD alarms/errors, it resolves the errors, clears the alarms, copies the current download status table to the last table, and clears out the current table.

**Table 533: Firmware Download Test (#1413) 1 of 3**

| Error Code    | Test Result | Description / Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

## Network Region Interconnectivity Test (#1417)

This test does not specify and list Error Codes in the usual manner. If this test detects a failure, the test is retried using different IP endpoints, if available, from the same two network regions. If the test still fails between these network regions:

1. Maintenance software marks the connectivity between them as "failed."
2. Communication Manager denies every attempted call between them.

For this test, devices that can serve as IP endpoints include:

- 1 IPMEDPRO
- 1 MEDPRO
- 1 CLAN-BD
- 1 IP phones or Softphones, with the ability to initiate a ping

For a network region without an IPMEDPRO, MEDPRO, or a CLAN-BD, Test #1417 looks for another ping-capable endpoint. If found, the region's testing continues. If not, the test assumes that the region's connectivity is operating normally.

This test runs on [NR-CONN \(Network-Region Connect\)](#).

## Echo Cancellor Test (#1420)

This test is destructive.

**Note:**

This test is executed only for USD1 circuit packs and DS1 Interface Media Modules that have been administered on the DS1 screen to provide echo cancellation. The circuit pack or media module must be busied out before this test is run.

The Echo Cancellor Test is part of the `test board long` demand test sequence of a UDS1 circuit pack or DS1 Media Module. The test checks echo cancellation on a subset of channels. If any channel fails twice or if any two channels fail once, the test fails and echo cancellation is bypassed on every channel of the board. Otherwise, the test passes and echo cancellation is configured to the administered parameters.

This test runs on [MG-DS1 \(DS1 Interface Media Module\)](#) and [UDS1-BD \(UDS1 Interface Circuit Pack\)](#).

**Table 535: Echo Canceller Test (#1420)**

## Short IP 2-Way Transmission Test (#1505)

This test attempts to verify IP network connectivity between one pair of IP Media Processors which are connected to a customer's LAN/WAN IP network.

This test creates a G.711 audio path between the source IP Media Processor specified in the command line and a destination IP Media Processor. The destination IP Media Processor is chosen by the system. The destination IP Media Processor is chosen from a port network other than the port network containing the source IP Media Processor. In addition, the destination IP Media Processor is chosen from the same IP network region as the source IP Media Processor or is chosen from an IP network region that is administered to be connected to the IP network region of the source IP Media Processor.

An audio channel using G.711 is setup between both boards. A 1004-Hz test tone is transmitted from the source PN to the destination PN over the G.711 audio channel. The test tone is then transmitted from the destination PN to the source PN.

This test runs on [IPMEDPRO \(IP Media Processor\)](#).

## Long IP 2-Way Transmission Test (#1506)

This test verifies IP network connectivity between a specified IP Media Processor and every other IP Media Processor in the system. It is an extended version of the [Short IP 2-Way Transmission Test \(#1505\)](#).

Test #1505 verifies IP voice connectivity in both directions between the specified IP Media Processor (A) and a system chosen destination IP Media Processor (B).

Test #1506 verifies IP voice connectivity in both directions between the specified IP Media Processor (A) and all other IP Media Processor/s (B, C, D, E, ....) that has administered IP network region connectivity to the IP network region of the source IP Media Processor.

The test passes if the source IP Media Processor (A) has 2-way voice connectivity to all other IP Media Processors. The test fails and stops immediately if the source IP Media Processor (A) cannot verify 2-way talk path to any destination IP Media Processor. The failure code indicates the port network that contains the destination Media Processor that could not be reached.

This test creates a G.711 audio path between the source IP Media Processor specified in the command line and a destination IP Media Processor. All destination Media Processors are chosen from the same IP network region as the source IP Media Processor and connected IP network regions. An audio channel using G.711 is setup between a pair of boards. A 1004-Hz test tone is transmitted from the source PN to the destination PN over the G.711 audio channel. The test tone is then transmitted from the destination PN to the source PN.

This test runs on [IPMEDPRO \(IP Media Processor\)](#).

## Verify NIC Options Test (#1511)

The Verify NIC Options Test checks if the circuit pack's network interface parameters (auto-negotiate, speed, and duplex) match with its administration.

The test passes if the NIC parameters match circuit pack administration. The test fails if the NIC parameters do not match.

This test runs on [IPMEDPRO \(IP Media Processor\)](#) and [ETH-PT \(Control LAN Ethernet\)](#).

| Error Code | Test Result | Description / Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                             |
|------------|-------------|------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------------|
| 1          | FAIL        | <p>The board's NIC is set to auto-negotiate. However, the transmission is set to half-duplex. It should be set to full-duplex. There is a mismatch between what is programmed on the board and what is administered in Communication Manager.</p> <ol style="list-style-type: none"> <li>1. Change the Ethernet options. Set the speed to <b>100Mbps</b> with <b>full duplex</b>. Set Auto (negotiate) to <b>n</b>. This should match the settings of the connected router. If the router does not have the same capabilities, you may have to adjust accordingly. The important thing is to make the media processor and the connected router match. The commands to change administration are:               <ol style="list-style-type: none"> <li>a. Enter <code>get ethernet-options location</code> to determine the current settings, both administered and actual.</li> <li>b. Enter <code>change ip-interface location</code> and change the <b>Enable Ethernet Port</b> field to <b>n</b> to turn off the interface. Submit the form to disable the interface.</li> <li>c. Enter <code>change ip-interface location</code> and change the Ethernet Options fields as required. Submit the form.</li> <li>d. Enter <code>change ip-interface location</code> and change the <b>Enable Ethernet Port</b> field to <b>y</b> to turn on the interface. Submit the form to enable the interface.</li> <li>e. Enter <code>get ethernet-options location</code> to verify that Ethernet options are the same in administration and on the board.</li> </ol> </li> <li>2. If service is normal and the alarm is causing concern, disable the test and escalate the problem.</li> </ol> |
|            |             | <b>2 of 3</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                            |

## Link State Audit Test (#1527)

This test verifies the Media Gateway H.248 link state and alarm state. If the user knows the MG is up but there is still an alarm indicating the link is down, this test should be run by using `test media-gateway location`.

This test runs on [MED-GTWY \(MEDIA GATEWAY\)](#).

**Table 539: Link State Audit Test (#1527)**

| Error Code | Test Result | Description / Recommendation                                                                                            |
|------------|-------------|-------------------------------------------------------------------------------------------------------------------------|
| 1007       | ABORT       | The media gateway is not administered.                                                                                  |
| 2012       | ABORT       | System call failed.<br>1. Retry the test at one-minute intervals up to 5 times.                                         |
| 1          | FAIL        | Gateway has been unregistered longer than the Link Loss Delay Timer.<br>1. A Major alarm is raised.                     |
| 257        | FAIL        | Link is up on a Survivable Remote Server.                                                                               |
| 769        | FAIL        | Gateway is in link bounce. It has been unregistered less than the Link Loss Delay Timer.<br>1. A Minor alarm is raised. |
|            | PASS        | The link is up and there is no alarm.                                                                                   |
|            |             |                                                                                                                         |

## Serial Bus Status Test (#1531)

The TN2312BP IPSI requests status information from the power supplies every 5 seconds. If it does not receive a response, or if it does not detect at least one power supply at initialization, it generates a serial bus failure error message. This test runs on [SER-BUS \(Serial Communication Bus\)](#).

Table 540: Serial Bus Status Test (#1531) 1 of 4

| Error Code   | Test Result | Description and recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                          |

|              | FAIL        | <p>The test failed.</p> <ol style="list-style-type: none"> <li>1. Enter <code>list configuration power-supply cab</code> and check if any power supplies are detected.</li> <li>2. Enter <code>list configuration all</code> and verify that the carrier locations for the power supplies appear correct. If not, verify that the paddle boards are inserted in the correct position for the carrier location.</li> <li>3. Use the following Serial Bus repair procedures: <p><b>Procedure 1:</b> This procedure removes and reinserts port circuit packs (those in the purple slots) one or more at a time. Use this procedure for each port circuit pack in the port network until the problem is resolved or until all circuit packs in the port network have been tried.</p> <ol style="list-style-type: none"> <li>1. If the Serial Bus problem is present when the circuit pack is inserted, but is resolved when the circuit pack is removed, either the circuit pack or the backplane pins in that slot are causing the problem.</li> <li>2. If the backplane pins are intact, replace the circuit pack.</li> </ol> <p>If some of the tests fail regardless of whether the circuit pack is inserted or removed, and the backplane pins are intact, the circuit pack is not the cause of the problem. In a multiple failure situation, the circuit pack could be one cause of the Serial Bus problem. However, other simultaneous failures might also be responsible for Serial Bus faults. Consider removing all circuit packs in the carrier and replacing them one at a time. However, if large service disruptions are to be avoided, work with one circuit pack at a time. This option is slower, but it disrupts only the users of a single circuit pack.</p> <ol style="list-style-type: none"> <li>3. Remove one or several circuit packs as appropriate. Any circuit packs that have been recently inserted should be checked first. If you decide to remove multiple circuit packs, consider working with an entire carrier at a time to more quickly and reliably determine which circuit packs are not the source of trouble. Do not remove the A carrier TN2312BP IPSI as it is the link back to the server.</li> </ol> </li> </ol> |
|              |             | <b>1 of 4</b>                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                           |

**Table 540: Serial Bus Status Test (#1531) 2 of 4**

| Error Code | Test Result      | Description and recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                 |

## Emergency Transfer Query Test (#1532)

The Emergency Transfer Query Test queries the maintenance module on the TN2312BP IPSI to determine if Emergency Transfer is set in MANUAL-ON or MANUAL-OFF mode. If Emergency Transfer is set to MANUAL-ON, a major alarm is generated. If Emergency Transfer is set to MANUAL-OFF, a warning alarm is generated.

This test is run on [CAB-EXFR \(Emergency Transfer\)](#).

## Power/Fan Lead Query Test (#1533)

The Power/Fan Query Test sends a request for the state of the power/fan lead (AuxSig) to the TN2312BP IPSI board in the G650 with an A carrier address. If the lead is on, the test fails. If the lead is off, the test passes. This test runs on [CAB-PFL \(Power Fan Lead\)](#).

**Table 542: Power/Fan Lead Query Test (#1533) 1 of 3**

## Power Supply Recycle Test (#1534)

The Power Supply Recycle Test verifies that the redundant power supply (slot 15) can fully support the power load for the G650, or shuts down the power to an entire carrier to force all the circuit boards in the carrier to recycle. This test turns off the DC output voltages for a few seconds and then turns the voltages back on. This test is run as a scheduled test only if redundant power supplies are present and then only on one power supply at a time. When redundant power supplies are present, this test can generate error log entries for either power supply.

This test runs on [POW-SUP \(Power Supply\)](#).

## **Power Supply Detection Test (#1535)**

The power supply detection test verifies that:

- 1 The power supply is detected.
- 1 No internal failures are reported.
- 1 Input power is present.

When redundant power supplies are present, the microcontroller for a power supply may still be powered, even though input power to the power supply is not present.

This test runs on [POW-SUP \(Power Supply\)](#).

1. It is unlikely that these failure codes will occur when redundant power supplies are present because each power supply is measuring the backplane voltage rather than the power supply voltage.

---

## Power Supply Voltage Test (#1536)

The TN2312BP IPSI scans the status of each 655A power supply on the serial bus every 5 seconds. This test returns the status of the most recent scan of the 655A DC output voltages.

This test runs on [POW-SUP \(Power Supply\)](#).

1. The values of these failure codes might be added together. For example, a value of 3 indicates that both the +5V and the -5V are out of tolerance or a value of 15 indicates that all four voltages are out of tolerance.

## Power Supply Temperature Test (#1537)

The power supply temperature test runs on [CAB-TEMP \(Cabinet Temperature\)](#). It provides the status of the following temperatures:

- 1 Inlet to the power supply (120F/49C)
- 1 Carrier exhaust (120F/49C)
- 1 Power supply hot spot status

**Table 546: Power Supply Temperature Test (#1537) 1 of 2**

## Ring Generator Interchange Test (#1539)

The ring generator interchange test causes a temporary interchange and is only used if the G650 has redundant power supplies. This test sends a command to the primary power supply in slot 0 to turn off ringing voltage, the ring arbitration lead changes state, and the secondary power supply in slot 15 provides ringing voltage to the backplane. The ring detection circuit for the secondary power supply is checked to verify that the secondary power supply is providing ringing voltage.

A command is sent to the primary power supply to apply ringing. The ring arbitration lead changes back to allow the primary power supply to provide ringing voltage. The ring voltage detection circuit on the primary power supply is checked to verify that the primary supply is applying ring voltage.

The long test sequence causes a ring interchange. The short test, which is the default, does not cause a ring interchange.

This test runs on [PS-RGEN \(Power Supply Ring Generator\)](#).

**Table 548: Ring Generator Interchange Test (#1539) 1 of 2**

---

## Ring Generator Status Test (#1540)

The ring generator status test verifies that the power supply ring voltage detector detects the presence of ringing voltage. The operational status information from the ring generator does **not** indicate that the generator is:

- 1 shut down because it has an internal fault or shorted lead
- 1 active but its output is operating under overload

This test does not fail if the ring selector switch on the 655A power supply is disabled.

This test runs on This test runs on [PS-RGEN \(Power Supply Ring Generator\)](#).

**Table 549: Ring Generator Status Test (#1540)**

## Correct Board Test (#1546)

A TN2312BP IPSI or TN8412 SIPI circuit pack is required for the environmental functions to work in the G650 or CMC1 media gateway. This test verifies that the proper circuit pack is inserted in the G650 or CMC1.

The G600 can have either a TN2312A or TN2312B IPSI circuit pack.

This test runs on [CAB-MTCE \(Media Gateway Maintenance\)](#).

**Table 551: Correct Board Test (#1546)**

| Error Code | Test Result | Description and recommendation                                                                                                                  |

| 2033<br>2500 | ABORT       | Internal system error.<br>Internal operation failed. Possible unknown cabinet type.<br>1. Repeat the command at one-minute intervals up to 3 times.         |
|              | FAIL        | The TN2312BP in carrier A is missing. This test will also fail if an incorrect response or no response from firmware is received when the board is queried. |
|              | PASS        | The correct board is present and a valid response was received.                                                                                             |
|              |             |                                                                                                                                                             |

---

## Environmental Maintenance Initialization Test (#1548)

The Environmental Maintenance Initialization Test is executed when an IPSI circuit pack is inserted and the board and media gateway type is determined. When a TN2312AP is inserted in a CMC1, G600, or G650, the Power Fan Lead (AuxSig) environmental maintenance is enabled.

When a TN2312BP IPSI is inserted in either a CMC1 or G600, Communication Manager sends the following messages to the embedded software (firmware) on the board:

- 1 Enable environmental maintenance (Power Fan lead)
- 1 A query to verify that environmental maintenance is enabled

## Maintenance Demand Tests

When a TN2312BP IPSI is inserted in a G650, Communication Manager sends the following messages to embedded software (firmware) on the board:

- 1 Enable environmental maintenance
- 1 Enable power supply insertion
- 1 Enable power supply audits
- 1 A query to verify that environmental maintenance is enabled
- 1 A query to verify that power supply insertion is enabled
- 1 A query to verify that power supply audits are enabled

This test runs on [CAB-MTCE \(Media Gateway Maintenance\)](#).

**Table 553: Environmental Maintenance Initialization Test (#1548)**

| Error Code           | Test Result | Description and recommendation                                                                                                                                                                                                                                                      |

## AESVCS Session Level Link Status Test (#1623)

The Application Enablement Services (AESVCS) Session Level Link Status Test determines if any AESVCS Links are associated with a given AESVCS Session. This test is run on [AESV-LNK \(AE Services Link\)](#).

**Table 557: AESVCS Session Level Link Status Test (#1623)**

| Error Code | Test Result | Description / Recommendation                                                                  |
|------------|-------------|-----------------------------------------------------------------------------------------------|
| 1124       | ABORT       | AE Services Server is disabled on the AE Services Administration page of the IP Services form |
|            | FAIL        | No AESVCS links are associated with this session.                                             |
|            | PASS        | At least one AESVCS link is assigned.                                                         |
|            |             |                                                                                               |

## AESVCS Link Heartbeat Test (#1624)

The Application Enablement Services (AESVCS) Link Heartbeat Test sends a TCP tunnel connection heartbeat message to the far end AESVCS Server. If the AESVCS Server fails to return a response to the heartbeat message, the test fails. An AESVCS Link that fails a Heartbeat test is subsequently deleted from the AESVCS Session.

This test is run for [AESV-LNK \(AE Services Link\)](#) and [AESV-SES \(AE Services Session\)](#).

**Table 558: AESVCS Link Heartbeat Test (#1624)**

| Error Code | Test Result | Description / Recommendation                                                             |
|------------|-------------|------------------------------------------------------------------------------------------|
|            | FAIL        | The heartbeat test failed.<br>1. Check the network connectivity and check the AE Server. |
|            | PASS        | The heartbeat test passed.                                                               |
|            |             |                                                                                          |

## Aggregator Hardware Query (#1629)

This test queries the status of the aggregator hardware on the IP Media Processor. The host processor and aggregator hardware work in tandem to implement an IP network interface supporting VoIP connectivity.

If the status is bad, the DSPs are taken out-of-service and a reset of the aggregator hardware is attempted. If the reset is successful, the DSPs are placed back into service.

This test runs on [IPMEDPRO \(TN2602AP IP Media Resource 320\)](#).

**Table 559: Aggregator Hardware Query (#1629)**

| Error Code                   | Test Result | Description / Recommendation                                                                                                                                                                                                                               |

## Packet Count Query Test (#1630)

This test sends a request for a count of packets received by the firmware from the LAN bus on the TN2602AP IP Media Processor. This test is based on the Medpro DSP looparound test. The Packet Count Query requests the packet count value from the IP Media Processor, runs the looparound test on an available port, then requests a second packet count value from the IP Media Processor. If the second value is greater than the first, then the packet bus is working. If the second value is not greater than the first, then there is a problem with the packet bus.

This test runs on [IPMEDPRO \(TN2602AP IP Media Resource 320\)](#).

**Table 560: Packet Count Query Test (#1630) 1 of 3**

| Error Code    | Test Result | Description / Recommendation                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                                  |

## System Link Status (#1647)

This test queries the circuit pack for the status of the serial link.

This test runs on [S8400-BD \(S8400 Server\)](#).

Table 561: System Link Status Test (#1647)

| Error Code | Test Result | Description / Recommendation                                                                                                                        |

## Power Supply Aux Signal Test (#1649)

The power supply aux signal test identifies which 655A power supply is asserting the AUXSIG lead. The test fails if the lead is being asserted by the power supply under test.

A POW-SUP Major alarm will be generated when the AUXSIG lead is asserted in a G650 carrier without duplicated power supplies.

A POW-SUP Minor alarm will be generated when the AUXSIG lead is asserted by a power supply in a G650 carrier with duplicated power supplies.

The test may abort for a power supply in a carrier that does not have duplicated power supplies since the microcontroller for the power supply may not have power when the power supply fails.

This test runs on [POW-SUP \(Power Supply\)](#).

**Table 562: Power Supply Aux Sig Test (#1649) 1 of 2**

## Media Gateway Announcement Module Test (#1683)

The Media Gateway Announcement Module test (#1683) is nondestructive and performs the following:

- 1 Checks the status of the Media Gateway Announcement module—verifies whether the Compact Flash is turned on in the change media gateway administration form.
- 1 Makes status inquiries to the Media Gateway Announcement Module—requests for data from the module to inquire whether the module is currently experiencing any problems related to the Compact Flash.

This test runs as part of periodic and scheduled maintenance as well as initialization and analysis.

When running the demand test, the Media Gateway Announcement module can respond with any of the following:

- 1 **Failure code 1:** if the Compact Flash is enabled, but not present, or not recognized, or there are no announcements found after a reset.
- 1 **Failure code 2:** if the Compact Flash is enabled and is present, but there is not enough RAM to support it.
- 1 **Failure code 4:** if the Compact Flash is enabled and is present, but there is not enough memory left on it.

The Media Gateway Announcement module can respond with multiple failures to a single query and make the error condition a combination of errors. If the board has multiple failures, the error codes are effectively in a logical order together.

This test also queries the module for the size of the Compact Flash and the amount of memory used on the Compact Flash.

**Note:**

Even if the Media Gateway Announcement Module test fails, the announcement module does not go out of service. However, the announcements may not be in good working condition and recording new announcements may fail.

## NO BOARD

No board was detected by the test. The test could not relate the internal ID to the port. This could be due to incorrect translations, no board is inserted, an incorrect board is inserted, or an insane board is inserted.

1. Enter **display errors** and check the Error Log for Error Type 125 (wrong board) or Error Type 131 (no board). Resolve either of these issues, if applicable.
2. Verify that the board is properly translated and inserted by using **list configuration**. Resolve any problems.
3. For DS1/UDS1 boards, use **add ds1 location** to administer the DS1 interface if it is not already administered.
4. If the board was already administered correctly, check the Error Log to determine whether the board is hyperactive (Error Type 1538). If so, the board was shut down. Reseating the board will re-initialize it.
5. If the circuit pack is correctly inserted, enter the following commands:
  - | **busyout board location**
  - | **reset board location**
  - | **release board location**
  - | **test board location long**

This should re-establish the linkage between the internal ID and the port. If not, verify that a valid board is inserted.

**Note:**

Hyperactivity causes some special problems with the sequence suggested above. If the ports are translated after entering **list config** but the **Vintage** field reports that there is no board when there really is a board, then the **busyout board** and **release board** commands will not work even though **reset board location** will work. The switch will put the hyperactive board back in service after the hyperactivity clears.

---

## Hyperactive DS1/UDS1 Interface Circuit Pack/Media Module

Error type 1538 in the error log indicates hyperactivity. The hyperactive DS1 board is out of service and one or more of the following symptoms may be exhibited.

- | The DS1 board tests such as test 138 and test 139 abort with error code 2000.

- | The tests run on the ports are returning NO BOARD.
- | A **busyout** or a **release** command has no affect on the test results.
- | A **list config** command shows that the circuit pack or media module and the ports are properly installed.

When hyperactivity occurs, the DS1 board is isolated from the system, and all of its trunks are placed into the out-of-service state. The system will try to restore the DS1 board within 15 minutes. When no faults are detected for 15 minutes, the DS1 board is restored to normal operation and every DS1 interface trunk is returned to the in-service state.

Hyperactivity is often caused by the associated facility. In this case, faults such as slips, misframes, or blue alarms would be entered in the error log. In addition, many hardware errors would be logged against the associated trunk circuits.

If the facility is OK and the error occurs again after 15 minutes, escalate this problem.

---

## Repair Procedures for DS1/UDS1 Circuit Pack/Media Module

---

### T1 Network Facility Procedures

If the DS1/UDS1 circuit pack or Media Module connects to a T1 network facility or to another switch, do the following:

1. Verify that both endpoints of the DS1 link are administered using the same signaling mode, framing mode, and line coding.
2. Contact the T1 Network Service or a technician at the far-end switch to diagnose the remote DS1 endpoint.
3. Check the physical connectivity of the DS1 boards and of the cable.
4. Replace the local DS1/UDS1 circuit pack or media module, and repeat the test.

---

### Line-side Terminating Device Procedures

If the DS1/UDS1 circuit pack or media module connects to a line-side terminating device such as a PRI terminal adapter, do the following.

1. Verify that the switch DS1 and the line-side terminating device are administered using the same signaling mode, framing mode, and line coding.

## Maintenance Demand Tests

2. Investigate the maintenance status of the line-side terminating device. Refer to the 'Line-Side Terminating Device Operating Manual' for information.
3. Contact the vendor of the line-side terminating device to diagnose the equipment.
4. Check the physical connection of the DS1 board to the terminating device, and check the premise distribution system or the intra-premise wiring for physical connection failures.
5. Replace the local DS1/UDS1 Interface circuit pack or media module and repeat the test.
